| OMEG _n | The <i>n</i> th rotating speed. |

Remarks:

1. **Equilibrium Equation.** The equilibrium equations depend on the reference frame. For the rotating coordinate system, the linearized equilibrium equation is given by

$$\mathbf{M}\ddot{\mathbf{u}} + (\mathbf{D} + 2\Omega\mathbf{C})\dot{\mathbf{u}} + (\mathbf{K} - \Omega^2\mathbf{K}_G)\mathbf{u} = \mathbf{F}.$$

Whereas, in a fixed coordinate system, the linearized equilibrium equation is

$$\mathbf{M}\ddot{\mathbf{u}} + (\mathbf{D} + \Omega\mathbf{C})\dot{\mathbf{u}} + \mathbf{K}\mathbf{u} = \mathbf{F}$$

with

- \mathbf{M} = lumped mass matrix
- \mathbf{D} = damping matrix
- \mathbf{K} = stiffness matrix
- \mathbf{C} = gyroscopic matrix
- \mathbf{K}_G = centrifugal stiffness matrix
- \mathbf{u} = nodal displacement vector
- $\dot{\mathbf{u}}$ = nodal point velocities at time
- $\ddot{\mathbf{u}}$ = nodal point acceleration at time
- Ω = rotating speed

The chief difference between the equations for the rotating and fixed frames is the inclusion of the centrifugal stiffness matrices \mathbf{K}_g . Additionally, the coefficient on the gyroscopic matrix, \mathbf{C} , as well as its content are modified in the rotating-frame case. Specifically, the rotating system includes an additional Coriolis contribution to \mathbf{C} .

2. **Spin Softening and Gyroscopic Effects.** Rotational Dynamics generates additional terms of spin softening and gyroscopic effects. For transient simulations adding both terms makes the stiffness matrix nonsymmetric which doubles the storage and cost for the numerical factorization. For large problems the user might consider using `ISTFNS = 2` which adds only the spin softening terms. This feature maintains the symmetry of the stiffness matrix, hence, avoiding the doubling of the cost of the numerical factorization. No matter the value of `ISTFNS`, all the effects of rotational dynamics are included in the force computation.
3. **Eigen-Frequencies.** In many applications of rotational dynamics, the critical speed – the theoretical angular velocity that excites the natural frequency of a rotating object – is of particular concern. Therefore, the study of mode frequency response with the change of the rotating speed is very important. The Campbell diagram, which is defined to represent a system's eigen-frequencies as a function of rotating speeds, is introduced for this purpose. In order to do this, the user needs to define a set of rotating speeds on Card 2, and LS-DYNA will do modal analysis for each of these speeds. `NOMEGA` should be defined as the number of rotating speeds specified in Card 2. A keyword file example in this application can be set as follows:

```

VARIABLE**DESCRIPTION**

NSOLVR

Solution method for implicit analysis:

EQ.-1: Multistep linear

EQ.1: Linear

EQ.12: Nonlinear with BFGS updates + optional arc length, (default) incorporating different line search and integration schemes compared to solver 2.

EQ.2: Nonlinear with BFGS updates (obsolete)

EQ.3: Nonlinear with Broyden updates

EQ.4: Nonlinear with DFP updates

EQ.5: Nonlinear with Davidon updates

EQ.6: Nonlinear with BFGS updates + arc length

EQ.7: Nonlinear with Broyden updates + arc length

EQ.8: Nonlinear with DFP updates + arc length

EQ.9: Nonlinear with Davidon updates + arc length

ILIMIT

Iteration limit between automatic stiffness reformations

MAXREF

Stiffness reformation limit per time step.

LT.0: If |MAXREF| matrix reformations occur, convergence for that time step is forced; see Remarks.

DCTOL

Displacement relative convergence tolerance

ECTOL

Energy relative convergence tolerance

RCTOL

Residual (force) relative convergence tolerance (DE-

| VARIABLE | DESCRIPTION |
|----------|---|
| | FAULT = inactive) |
| LSTOL | Line search convergence tolerance |
| ABSTOL | Absolute convergence tolerance. LT.0: Convergence detected when the residual norm is less than ABSTOL . Tip: To drive convergence based on ABSTOL , set DCTOL and ECTOL to 1.0E-20. |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|--------|-------|---------|--------|---------|-------|---|
| Variable | DNORM | DIVERG | ISTIF | NLPRINT | NLNORM | D3ITCTL | CPCHK | |
| Type | I | I | I | I | F/I | I | I | |
| Default | 2 | 1 | 1 | 0 | 2 | 0 | 0 | |

Strict Tolerances Optional Card. Define this card if and only if DNORM is less than 0.

| Card 2.1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|---|-------|-------|-------|-------|
| Variable | DMTOL | EMTOL | RMTOL | | NTTOL | NRTOL | RTTOL | RRTOL |
| Type | F | F | F | | F | F | F | F |
| Default | 0.0 | 0.0 | 0.0 | | 0.0 | 0.0 | 0.0 | 0.0 |

| VARIABLE | DESCRIPTION |
|----------|---|
| DNORM | Displacement norm for convergence test EQ.1: Increment as a function of displacement over current step EQ.2: Increment as a function of total displacement (default) LT.0: DNORM ; also activates reading of optional Card 2.1. |
| DIVERG | Divergence flag (force imbalance increase during equilibrium iterations) |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | EQ.1: reform stiffness if divergence detected (default) EQ.2: ignore divergence |
| ISTIF | Initial stiffness formation flag: EQ.1: reform stiffness at start of each step (default) EQ.n: reform stiffness at start of every "n"th step |
| NLPRINT | Nonlinear solver print flag: EQ.0: no nonlinear iteration information printed (new v970 default) EQ.1: print iteration information to screen, message, d3hsp files EQ.2: print extra norm information (NLNORM = 1) EQ.3: same as 2, but also print information from line search NOTE: during execution, interactive commands can be used: <u>interactive command</u> <u>response</u> <ctrl-c> nlprint toggle NLPRINT between 0 and 1 <ctrl-c> diagnostic toggle NLPRINT between 0 and 2 <ctrl-c> information set NLPRINT = 2 for one iteration |
| NLNORM | Nonlinear convergence norm type, input an integer if zero or a positive number is used and float if a negative value is used LT.0: Same as 4, but rotational degrees of freedom are scaled with characteristic length NLNORM to account for units. See Remarks. EQ.1: consider translational and rotational degrees of freedom EQ.2: consider translational degrees of freedom only (default) EQ.4: consider sum of translational and rotational degrees of freedom, i.e., no separate treatment. See remarks. |
| D3ITCTL | Control d3iter database. If nonzero, the search directions for the nonlinear implicit solution are written to the d3iter database. To reduce the size of the d3iter database the database is reset every n time steps where n = d3itctl. |
| CPCHK | Contact penetration check flag. This flag does not apply to mortar contacts. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | EQ.0: no contact penetration check is performed (default). EQ.1: check for contact penetration during the nonlinear solution procedure. If such penetration is found modify the line search to prevent unnecessary penetration. |
| DMTOL | Maximum displacement convergence tolerance; convergence is detected when the <i>relative</i> maximum nodal or rigid body displacement is less than this value |
| EMTOL | Maximum energy convergence tolerance; convergence is detected when the <i>relative</i> maximum nodal or rigid body energy increment is less than this value |
| RMTOL | Maximum residual convergence tolerance; convergence is detected when the <i>relative</i> maximum nodal or rigid body residual is less than this value |
| NTTOL | Nodal translational convergence tolerance; convergence is detected when the <i>absolute</i> maximum nodal translational residual is less than this value |
| NRTOL | Nodal rotational convergence tolerance; convergence is detected when the <i>absolute</i> maximum nodal rotational residual is less than this value |
| RTTOL | Rigid body translational convergence tolerance; convergence is detected when the <i>absolute</i> maximum rigid body translational residual is less than this value |
| RRTOL | Rigid body rotational convergence tolerance; convergence is detected when the <i>absolute</i> maximum rigid body rotational residual is less than this value |

Arc Length Optional Card. The contents of this card are ignored unless an arc-length method is activated ($6 \leq \text{NSOLVR} \leq 9$, or $\text{NSOLVR} = 12$ and $\text{ARCMTH} = 3$).

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|-----------|---------|--------|--------|--------|--------|--------|
| Variable | ARCCTL | ARCDIR | ARCLLEN | ARCMTH | ARCDMP | ARCPSI | ARCALF | ARCTIM |
| Type | I | I | F | I | I | F | F | F |
| Default | 0 | see below | 0. | 1 | 2 | 0. | 0. | 0. |

VARIABLE**DESCRIPTION**

| | |
|---------|---|
| ARCCTL | Arc length controlling node ID EQ.0: generalized arc length method |
| ARCDIR | Arc length controlling node direction (ignored if $\text{ARCCTL} = 0$ above) EQ.1: global x -translation EQ.2: global y -translation EQ.3: global z -translation |
| ARCLLEN | Relative arc length size. See remarks below. LE.0.0: use automatic size, GT.0.0: use $\text{ARCLLEN} \times (\text{automatic step size})$. |
| ARCMTH | Arc length method EQ.1: Crisfield (default) EQ.2: Ramm EQ.3: Modified Crisfield (used with $\text{NSOLVR} = 12$ only) Note: When using Arc-length method, termination should be based on some criteria using <i>*TERMINATION_OPTION</i> keyword. |
| ARCDMP | Arc length damping option EQ.2: off (default) EQ.1: on, oscillations in static solution are suppressed |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| ARCPSI | Relative influence of load/time parameter in spherical arclength constraint; default value is 0 which corresponds to a cylindrical arclength constraint. Applies to ARCMTH = 3. |
| ARCALF | Relative influence of predictor step direction for positioning of the arc center; default is 0 which means that the center is at the origin. Applies to ARCMTH = 3. |
| ARCTIM | Optional time when arclength method is initiated. Applies to ARCMTH = 3. |

Line Search Parameter Optional Card.

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|------|------|------|------|---|---|
| Variable | LSMTD | LSDIR | IRAD | SRAD | AWGT | SRED | | |
| Type | I | I | F | F | F | F | | |
| Default | 4 | 2 | 0.0 | 0.0 | 0.0 | 0.0 | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| LSMTD | Line search convergence method: EQ.1: Energy method using only translational variables EQ.2: Residual method EQ.3: Energy method using both translational and rotational variables EQ.4: Energy method using sum of translational and rotational degrees of freedom (default), that is, no separate treatment EQ.5: Same as 4, but account for residual norm growth to be extra conservative in step length EQ.6: Same as 5, but minimizes the residual norm whenever convenient. |
| LSDIR | Line search direction method: EQ.1: Search on all variables (traditional approach used in versions prior to 971) |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | EQ.2: Search only on the independent (unconstrained) variables |
| | EQ.3: Use adaptive line search (see AWGT, SRED) |
| | EQ.4: Use curved line search (see IRAD, SRAD) |
| IRAD | Normalized curvature factor for curved line search, where 0 indicates a straight line search and 1 indicates full curved line search. |
| SRAD | Radius of influence for determining curve in curved line search. For each independent node, all nodes within this radius are used for determining the curve. If 0, then all nodes connected to the same element as the independent node are used. |
| AWGT | Adaptive line search weight factor between 0 and 1. A high value tends to restrict the motion of oscillating nodes during the implicit process. |
| SRED | Initial step reduction between 0 and 1 for adaptive line search; use large number for conservative start in implicit procedure. |

Remarks:

| VARIABLE | REMARKS |
|-----------------|--|
| NSOLVR | <p>NSOLVR = 1 invokes a linear analysis for a user specified number of time steps. The results are cumulative for those time steps. NSOLVR = -1 resets the geometry back to the initial state for each time step. This allows a linear analysis for several different loading cases with only one stiffness matrix formation and factorization. If a linear analysis is selected, equilibrium checking and iterations are not performed.</p> <p>The Full Newton nonlinear solution method can be invoked by using the default BFGS solver, and selecting ILIMIT = 1 to form a new stiffness matrix every iteration.</p> <p>In the neighborhood of limit points the Newton based iteration schemes often fail. The arc length method of Riks and Wempner (combined here with the BFGS method) adds a constraint equation to limit the load step to a constant "arc length" in load-displacement space. This method is frequently used to solve snap through buckling problems. <u>When applying</u></p> |

| VARIABLE | REMARKS |
|-----------------|---|
| | <p><u>the arc-length method, the curves that define the loading should contain only two points, and the first point should be at the origin (0,0).</u> LS-DYNA will extrapolate, if necessary, to determine the load. In this way, time and load magnitude are related by a constant. It is possible that time can become negative in case of load reversal. The arc length method cannot be used in a dynamic analysis.</p> |
| ILIMIT | <p>In the default BFGS method, the global stiffness matrix is only reformed every ILIMIT iterations. Otherwise, an inexpensive stiffness update is applied. By setting ILIMIT= 1, a stiffness reformation is performed every iteration. This is equivalent to the Full Newton method (with line search). A higher value of ILIMIT (20-25) can reduce the number of stiffness matrix reformations and factorizations which may lead to a significant reduction in cost. Note that the storage requirements for implicit include storing 2 vectors per iteration. Large values of ILIMIT will cause substantial increase in storage requirements.</p> |
| MAXREF | <p>The nonlinear equilibrium search will continue until the stiffness matrix has been reformed MAXREF times, with ILIMIT iterations between each reformation. If equilibrium has not been found and MAXREF > 0, control will be passed to the automatic time step controller if it is activated. If the automatic time step controller is not active, error termination will result. When the auto time step controller is active, it is often efficient to choose MAXREF = 5 and try another stepsize quickly, rather than wasting too many iterations on a difficult step.</p> <p>When MAXREF < 0 and MAXREF matrix reformations have occurred, convergence for the current time step is declared, with a warning, and the simulation moves to the next time step. This option should be used with caution as the results for that particular time step may be wrong.</p> |
| DCTOL | <p>When the displacement norm ratio is reduced below DCTOL, this condition is satisfied. Smaller numbers lead to more accurate determination of equilibrium and, on the negative side, result in more iterations and higher costs. Use NLPRINT to display norm data each iteration.</p> |
| ECTOL | <p>When the energy norm ratio is reduced below ECTOL, this condition is satisfied. Smaller numbers lead to more strict determination of equilibrium and, on the negative side, result in</p> |

| VARIABLE | REMARKS |
|-----------------|--|
| | more iterations and higher costs. Use NLPRINT to display norm data each iteration. |
| RCTOL | When the residual norm ratio is reduced below RCTOL, this condition is satisfied. Smaller numbers lead to more strict determination of equilibrium and, on the negative side, result in more iterations and higher costs. By default this convergence criterion is effectively disabled using RCTOL = 1.e10. Use NLPRINT to display norm data each iteration. |
| DMTOL, etc. | For all nonzero values of the strict tolerance fields in optional Card 2b, the associated criterion must be satisfied <i>in addition</i> to the ones defined through DCTOL, ECTOL, and RCTOL. These criteria are based on the maximum norm, which is regarded as stronger than the Euclidian norm used for the other parameters, and using them will likely result in higher accuracy at the price of more iterations. For NLPRINT greater than or equal to 2, a table is listed in the message and d3hsp files for each iteration, providing the values associated with all the criteria activated. The first three (DMTOL, EMTOL and RMTOL) of these extra fields are unitless and honor the meaning of both DNORM and NLNORM. The last four (NTTOL, NRTOL, RTTOL and RRTOL) are to be given in units of force, torque, force and torque, respectively, and the values used should account for the representative loads in the problem as well as the discretization size. |
| LSTOL | A line search is performed on stiffening systems to guard against divergence of Newton-based nonlinear solvers. With the Full Newton method, it is sometimes helpful to define a large value (LSTOL = 9999.0) to effectively disable line search. |
| DNORM | When computing the displacement ratio, the norm of the incremental displacement vector is divided by the norm of "total" displacement. This "total" displacement may be either the total over the current step, or the total over the entire simulation. The latter tends to be more lax, and can be poor at the end of simulations where large motions develop. For these problems, an effective combination is DNORM = 1, and DCTOL = 0.01 or larger. |
| DIVERGE | By default, a new stiffness matrix is formed whenever divergence (growing out-of-balance force) is detected. This flag can be used to suppress this stiffness reformation. |

| VARIABLE | REMARKS |
|----------|---|
| ISTIF | <p>By default, a new stiffness matrix is formed at the start of every time step. Suppressing this stiffness reformation can decrease the cost of simulations which have many tiny steps that are mostly linear, such as transient dynamics.</p> |
| NLPRINT | <p>This flag controls printing of displacement and energy convergence measures during the nonlinear equilibrium search. If convergence difficulty occurs, this information is helpful in determining the problem.</p> |
| NLNORM | <p>By default, only translational degrees of freedom are used in evaluating convergence norms. Use this flag to include rotational degrees of freedom, or to make additional data available for diagnosing convergence problems.</p> <p>This additional data includes the worst offending node and degree of freedom contributing to each norm. Rotational degrees of freedom can be considered independently from the translational degrees of freedom, meaning that two separate scalar products are used for evaluating norms, $\langle \mathbf{u}, \mathbf{v} \rangle_t = \mathbf{u}^T \mathbf{J}_t \mathbf{v}$ and $\langle \mathbf{u}, \mathbf{v} \rangle_r = \mathbf{u}^T \mathbf{J}_r \mathbf{v}$. Here \mathbf{J}_t and \mathbf{J}_r are diagonal matrices with ones on the diagonal to extract the translational and rotational degrees of freedom, respectively. This is the option $\text{NLNORM} = 1$, and the convergence criteria must be satisfied for both translational and rotational degrees of freedom simultaneously.</p> <p>Alternatively they can be included by defining the single scalar product $\langle \mathbf{u}, \mathbf{v} \rangle = \langle \mathbf{u}, \mathbf{v} \rangle_t + \lambda_u \lambda_v \langle \mathbf{u}, \mathbf{v} \rangle_r$, where λ_u and λ_v are scale factors to account for different units of the rotational degrees of freedom. For $\text{NLNORM} = 4$ these scale factors are equal to a characteristic element size that is calculated internally, but for $\text{NLNORM} < 0$ λ_u is equal to NLNORM if \mathbf{u} is a displacement vector and $\text{NLNORM} ^{-1}$ if it is a force vector, and the same goes for the pair λ_v and \mathbf{v}. So NLNORM is a characteristic length that appropriately weighs translational and rotational degrees of freedom together. For $\text{NLNORM} = 4$ the internally calculated size is echoed to the screen, d3hsp and message files for observation and based on this $\text{NLNORM} < 0$ can be used if another scale factor is more suitable.</p> |
| ARCCTL | <p>The arc length method can be controlled based on the displacement of a single node in the model. For example, in dome reversal problems the node at the center of the dome can</p> |

| VARIABLE | REMARKS |
|-----------------|---|
| | be used. By default, the generalized arc length method is used, where the norm of the global displacement vector controls the solution. This includes all nodes. |
| ARCLLEN | In many cases the arc length method has difficulty tracking the load displacement curve through critical regions. Using $0 < \text{ARCLLEN} < 1$ will reduce the step size to assist tracking the load-displacement curve with more accuracy. Use of $\text{ARCLLEN} < 1$ will cause more steps to be taken. Suggested values are 1.0 (the default), 0.5, 0.25, and 0.10. |
| ARCDMP | Some static problems exhibit oscillatory response near instability points. This option numerically suppresses these oscillations, and may improve the convergence behavior of the post-buckling solution. |
| LMSTD | The default method for determining convergence of the nonlinear line search is to find the minimum of the energy. This parameter allows choosing the energy on only the translational variables, energy of both the translational and rotational variables, or for minimizing the residual (forces). The effect of using a residual based line search is not always positive; sometimes it is too restrictive and stops convergence. But it is a more conservative approach than using the energy based method since it explicitly controls the norm of the residual. It should not be seen as a better strategy than the energy method but as an alternative to try in cases when the default method seems to be working poorly. Line search methods 5 and 6 are conservative line search methods to be used for highly nonlinear problems; these should not be used as default but as final resorts to potentially resolve convergence issues. The rule of thumb is that the $\text{LSMTD} = 5$ is slow but robust and $\text{LSMTD} = 6$ is even slower but more robust. |
| LSDIR | In Version 971 of LS-DYNA new line search options were added. The traditional approach ($\text{LSDIR} = 1$) computes the line search direction using all variables. The new (default) approach of $\text{LSDIR} = 2$ computes the line search direction only on the unconstrained variables. It has proven to be both robust and more efficient. We have also included two new approaches to try for problems where the default and traditional approach fail and the user is using Full Newton ($\text{ILIMIT} = 1$). See the next two remarks for more information on those methods. |

| VARIABLE | REMARKS |
|-----------------|--|
| IRAD / SRAD | <p>The parameters IRAD and SRAD are for the curved line search (LSDIR = 4). The first parameter is a switch (0 or 1) to invoke this line search; an intermediate value is interpreted as weighted combination of a straight and curved line search (the curvature radius is decreased with increasing IRAD). A value of unit is recommended in situations with rather smooth responses, such as springback. Also, IRAD = 1 seems to work best with full Newton iterations. The SRAD parameter should be equal to 0 for most cases; this means that the search curve for a node is determined from the search direction of nodes connected to the same elements as that node. SRAD > 0 is interpreted as a radius of influence, meaning that the search curve for a node is determined from the search direction of nodes within a distance SRAD of this node. This option was introduced as an experiment to see if this had a smoothing and stabilizing effect. A value of 0.0 is currently recommended.</p> |
| AWGT / SRED | <p>The parameters AWGT and SRED are for the adaptive line search. The intention is to improve robustness for problems that have tendencies to oscillate or diverge, indicated by the dnorm and enorm parameter outputs in the iterations (stdout). A value of 0.5 is recommended for AWGT as a starting point. With a nonzero value the motions of individual nodes are tracked. For nodes that are oscillating (going back and forth in space), the maximum step size for the next iteration is reduced in proportion to the parameter AWGT, and for nodes that are not oscillating but going nicely along a straight path, the maximum step size for the next iteration is increased in proportion to 1-AWGT.</p> <p>In test problems, the introduction of the adaptive line search has stabilized the implicit procedure in the sense that the dnorm and enorm values are more monotonically decreasing until convergence with virtually no oscillations. If a problem is still oscillating or diverging, the user should try to increase the AWGT parameter since this is a more restrictive approach but probably gives a slower convergence rate. An option for nasty problems is also to use SRED > 0 which is the initial step reduction factor (less than 1). This means that the initial step size is reduced by this value but the maximum step size will increase by an amount that is determined by the success in the iterative procedure; eventually it will reach unity. It can never decrease. Also here, it is intended to be used with full Newton</p> |

VARIABLE**DESCRIPTION**

LSOLVR

Linear equation solver method (see [Remark 1](#)).

EQ.2: Parallel multi-frontal sparse solver (default)

EQ.22: iterative, CG with diagonal preconditioner

EQ.23: iterative, CG with SGS preconditioner

EQ.24: iterative, CG with SSOR preconditioner

EQ.25: iterative, CG with modified ILDLTD preconditioner

EQ.26: iterative, CG with modified ILDLTO preconditioner that requires extra storage

EQ.90: User Supplied Linear Equation Solver (see [Remark 2](#))

SMP only:

EQ.6: BCSLIB-EXT, direct, sparse, double precision

EQ.10: iterative, best of currently available iterative methods

EQ.11: iterative, Conjugate Gradient method

EQ.12: iterative, CG with Jacobi preconditioner

EQ.13: iterative, CG with Incomplete Choleski preconditioner

EQ.14: iterative, Lanczos method

EQ.15: iterative, Lanczos with Jacobi preconditioner

EQ.16: iterative, Lanczos with Incomplete Choleski preconditioner

LPRINT

Linear solver print flag controls screen and message file output (see [Remarks 3](#) and [5](#)).

EQ.0: no printing

EQ.1: output summary statistics on memory, cpu requirements

| VARIABLE | DESCRIPTION |
|----------|--|
| NEGEV | <p>EQ.2: more statistics</p> <p>EQ.3: even more statistics and debug checking</p> <p>During execution, use the interactive command "<ctrl-c> lprint" to toggle this print flag between 0 and 1.</p> <p>Negative eigenvalue flag. Selects procedure when negative eigenvalues are detected during stiffness matrix inversion (see Remark 4).</p> |
| ORDER | <p>EQ.1: stop, or retry step if auto step control is active</p> <p>EQ.2: print warning message, try to continue (default)</p> <p>Ordering option (see Remark 5):</p> <p>EQ.0: method set automatically by LS-DYNA</p> <p>EQ.1: MMD, Multiple Minimum Degree.</p> <p>EQ.2: Metis</p> <p>EQ.4: LS-GPart</p> |
| DRCM | <p>Drilling rotation constraint method for shells (see Remark 6):</p> <p>EQ.1: add drilling stiffness (old Version 970 method)</p> <p>EQ.2: same as 4 below</p> <p>EQ.3: add no drilling stiffness</p> <p>EQ.4: add drilling stiffness (improved method) (default)</p> |
| DRCPRM | <p>Drilling rotation constraint parameter for shells. This parameter scales the drilling stiffness. For the old method (DRCM = 1) the default value of DRCPRM is 1.0 for linear analysis, 100.0 for nonlinear implicit analysis, and either 10^{-12} or 10^{-8} for eigenvalue analysis depending on the shell element type. For eigenvalue analysis, the input value for DRCPRM is ignored. For the improved method (default, DRCM = 4), the default value of DRCPRM is as described above for the old method except default DRCPRM is 1.0 for nonlinear implicit analysis.</p> |
| AUTOSPC | <p>Automatic Constraint Scan flag</p> <p>EQ.1: scan the assembled stiffness matrix looking for unconstrained, unattached degrees of freedom. Generate additional constraints as necessary to avoid negative eigenvalues.</p> <p>EQ.2: do not add constraints.</p> |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| AUTOTOL | AUTOSPC tolerance. The test for singularity is the ratio of the smallest singular value and the largest singular value. If this ratio is less than AUTOTOL, then the triple of columns is declared singular and a constraint is generated. Default values in single and double precision are 10^{-4} and 10^{-8} , respectively. |
| LCPACK | Matrix assembly package: EQ.2: Default. EQ.3: Same as 2, but incorporates a non-symmetric linear solver; see Remark 7 . |
| MTXDMP | Matrix and right-hand-side dumping. LS-DYNA has the option of dumping the globally assembled stiffness matrix and right-hand-side vectors files in Harwell-Boeing sparse matrix format. Such output may be useful for comparing to other linear equation solution packages. EQ.0: No dumping GT.0: Dump all matrices and right-hand-side vectors every MTXDMP time steps. The first dump occurs at the first time step, then at time step MTXDUMP+1, 2*MTXDUMP+1, and so on. Output is written as ASCII text and the involved filenames are of the following form: <u>K xxxx_yyy.mtx.rb</u> This file contains the stiffness matrix at step xxxx, iteration yyy. <u>M xxxx_yyy.mtx.rb</u> This file contains the mass matrix at step xxxx, iteration yyy. Only for eigenvalue analysis. <u>W xxxx_yyy.mtx.rb</u> This file contains the damping matrix at step xxxx, iteration yyy. Only for simulations with damping. <u>K xxxx_yyy_zzz.rhs.rb</u> This file contains the right hand side at step xxxx, iteration yyy, where yyy is the iteration at which a stiffness matrix is formed; and zzz is the cumulative iteration number for the step. The values of yyy and zzz don't always coincide because the stiffness matrix is not necessarily reformed every iteration. |

| VARIABLE | DESCRIPTION |
|----------|--|
| | <p style="text-align: center;"><u>Node Data xxxx yyy</u></p> <p>This file maps stiffness matrix to nodes and provides nodal coordinates.</p> <p>LT.0: Like positive values of MTXDMP but dumped data is binary.</p> <p>EQ. 9999]: Simulation is terminated after dumping matrices and right hand side prior to factorization.</p> |
| IPARM1 | For $22 \leq \text{LSOLVR} \leq 26$ only, maximum number of iterations. Default is 500. |
| RPARAM1 | For $22 \leq \text{LSOLVR} \leq 26$ only, absolute tolerance for convergence. Default is 10^{-10} . |
| RPARAM2 | For $22 \leq \text{LSOLVR} \leq 26$ only, relative tolerance for convergence. Default is 10^{-4} . |
| EMXDMP | <p>Flag for dumping elemental stiffness and mass matrices:</p> <p>EQ.0: No dumping</p> <p>GT.0: Dump all elemental matrices every EMXDMP time steps. Output is written as ASCII text and the involved filenames are of the following form:</p> <p style="text-align: center;"><u>ElmStfMtx xxxx yyy</u></p> <p>This file contains the elemental stiffness matrix at step xxxx, iteration yyy.</p> <p style="text-align: center;"><u>ElmMssMtx xxxx yyy</u></p> <p>This file contains the elemental mass matrix at step xxxx, iteration yyy.</p> <p>LT.0: Like positive values of MTXDMP but dumped data is binary.</p> <p>EQ. 9999]: Simulation is terminated after dumping matrices and right hand side prior to factorization.</p> |
| RDCMEM | Starting with LS-DYNA R11, the memory for linear algebra has been moved from static memory allocation to dynamic memory allocation. For implicit applications we have found that some operating systems are not "robust" when queried about how much dynamic memory is free. This factor caps the amount of dynamic memory requested for linear algebra applications to RDCMEM times the amount that the operating system declares available. 0.85 seems to work well for most systems. If you are using a workstation and starting up other applications while |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | running LS-DYNA, you may need to use a number like 0.50. |

Remarks:

1. **Direct versus Iterative Solvers.** The linear solver is used to compute the inverse of the global stiffness matrix, which is a costly procedure both in memory and CPU time. Direct solvers apply Gaussian elimination, while iterative solvers successively improve “guesses” at the correct solution. Iterative solvers require far less memory than direct solvers, but may suffer from convergence problems. Generally, iterative solvers are poor for automotive applications, but can be superior for large brick element models, such as solid models in civil engineering.
2. **User Supplied Solver.** Starting with R11, we have added a capability for a user supplied solver. Users can follow the template in the file UserLE.F90 to supply their own linear equation solver. Some examples are available in the usermat delivery and are available from LSTC Technical Support.
3. **Solver Print Flag.** Select printing of the timing and storage information (LPRINT = 1) if you are comparing performance of linear equation solvers, or if you are running out of memory for large models. Minimum memory requirements for in-core and out-of-core solution are printed. This flag can also be toggled using sense switch "<ctrl-c> lprint". *For best performance, increase available memory using “memory= ” on the command line until an IN-CORE solution is indicated.*

When using solver option 6, LPRINT = 2 and 3 will cause increased printed output of statistics and performance information.

4. **Negative Eigenvalues.** Negative eigenvalues result from underconstrained models (rigid body modes), severely deformed elements, or non-physical material properties. The NEGEV flag allows control to be passed directly to the automatic time step controller when negative eigenvalues are detected. Otherwise, significant numerical roundoff error is likely to occur during factorization, and equilibrium iterations may fail (see *CONTROL_IMPLICIT_AUTO).
5. **Reordering Cost.** The system of linear equations is reordered to optimize the sparsity of the factorization when using direct methods. Metis is an ordering method from University of Minnesota which is very effective for larger problems and for 3D solid problems, but also very expensive. MMD is inexpensive, but may not produce an optimum reordering, leading to higher cost during numeric factorization. MMD is usually best for smaller problems (less than 100,000 degrees of freedom).

Reordering cost is included in the symbolic factorization phase of the linear solver ($LSPRINT \geq 1$). For large models, if this cost exceeds 20% of the numeric factorization cost, it may be more efficient to select the MMD method.

Note that the values of $LPRINT$ and $ORDER$ also affect the eigensolution software. That is $LPRINT$ and $ORDER$ from this keyword card is applicable to eigensolution.

As of R11 an ordering method that scales in both memory and time is being developed. It should be used for Large MPP Implicit applications with 8 or more processes. Since it is still being developed, it is best not to use this ordering method unless Metis is not working for your application due to its serial nature and you are in contact with LSTC developers. Please refer to ***CONTROL_IMPLICIT_ORDERING** for additional parameters for order methods.

6. **Drilling Degree of Freedom.** To avoid a singular stiffness matrix for the implicit analysis of flat shell topologies, some constraint on the drilling degree of freedom is needed. The default method of applying this constraint, $DRCM = 4$, adds the consistent force vector for consistency and improved convergence as compared to the old method, $DRCM = 1$.

In explicit analysis, an unconstrained drilling degree of freedom is usually not a concern since a stiffness matrix is not used. However, special situations may arise in which the user wishes to include additional resisting rotational force in the drilling degree of freedom for improved robustness and/or accuracy. To activate the consistent drilling constraint in explicit analysis, use the input variables $DRCPSID$ and $DRCPRM$ for ***CONTROL_SHELL**.

7. **Non-Symmetric Matrix Solver.** Certain features may break the symmetry of the stiffness matrix. Unless $LCPACK$ is set to 3, these contributions are suppressed or symmetrized by the default symmetric linear solver. However, when $LCPACK$ is set to 3, a more general linear solver lifting the symmetry requirement is used. The solver for non-symmetric matrices is more computationally expensive.

For eigenvalue analysis, $LCPACK = 3$ is only implemented in SMP. For static and dynamic implicit analyses, $LCPACK = 3$ is implemented for both SMP and MPP.

Keywords for which the non-symmetric contribution is included when $LCPACK = 3$ are listed below. If none of these features are included in the model, setting $LCPACK = 3$ offers no benefit but will nevertheless incur additional computational cost.

***CONTACT_..._MORTAR:**

The mortar contact accounts for frictional non-symmetry in the resulting tangent stiffness matrix; the effects on convergence characteristics have not yet shown to be significant.

***LOAD_SEGMENT_NONUNIFORM:**

The non-symmetric contribution may be significant for the follower load option, $LCID < 0$.

***LOAD_SEGMENT_SET_NONUNIFORM:**

The non-symmetric contribution may be significant for the follower load option, $LCID < 0$.

***MAT_FABRIC_MAP:**

This stress map fabric model accounts for non-symmetry in the material tangent modulus, representing the non-linear Poisson effect due to complex interaction of yarns.

***SECTION_SHELL, *SECTION_SOLID:**

User defined resultant elements ($ELFORM = 101, 102, 103, 104, 105$ with $NIP = 0$) support the assembly and solution of non-symmetric element matrices.

***SECTION_BEAM:**

Belytschko-Schwer beam ($ELFORM = 2$) nonsymmetric geometric stiffness contribution is supported.

8. **Constraints.** Explicit treats all the constraints in sequence, which introduces the limitation of applying several constraints on the same DOF. Implicit (with $LCPACK$), on the other hand, treats all constraints simultaneously, which precludes (circumvents) the limitation on applying multiple constraints on the same nodes or DOFs, as long as they are not in conflict.

***CONTROL_IMPLICIT_STABILIZATION_{OPTION}**

Available options include:

<BLANK>

DYN

SPR

Purpose: This optional card applies to implicit calculations. Artificial stabilization is required for multi-step unloading in implicit springback analysis (see also *CONTROL_IMPLICIT_GENERAL). The DYN option allows setting controls specifically for the dynamic relaxation phase. The SPR option allows setting controls specifically for the springback phase.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-------|--------|------|---|---|---|---|
| Variable | IAS | SCALE | TSTART | TEND | | | | |
| Type | I | F | F | F | | | | |
| Default | 2 | 1.0 | ↓ | ↓ | | | | |

VARIABLE**DESCRIPTION**

IAS

Artificial Stabilization flag (see [Remark 2](#)):

EQ.1: active

EQ.2: inactive (default)

SCALE

Scale factor for artificial stabilization (see [Remark 3](#)). For flexible parts with large springback, like outer body panels, a value of 0.001 may be required.

EQ.-n: curve ID = n gives SCALE as a function of time

TSTART

Start time. (Default: immediately upon entering implicit mode)

TEND

End time. (Default: termination time)

Remarks:

1. **Artificial Stabilization.** Artificial stabilization allows springback to occur over several steps. This is often necessary to obtain convergence during equilibrium iterations on problems with large springback deformation. Stabilization is introduced at the start time TSTART, and slowly removed as the end time TEND is approached. Intermediate results are not accurate representations of the fully unloaded state. The end time TEND must be reached exactly for total springback to be predicted accurately.
2. **IAS Defaults.** The default for IAS depends on the analysis type in *CONTROL_IMPLICIT_GENERAL. For “seamless” springback analysis, automatic time step control and artificial stabilization are activated by default. Otherwise, IAS is inactive by default.
3. **Scale Factor.** SCALE is a penalty scale factor similar to that used in contact interfaces. If modified, it should be changed in order-of-magnitude increments at first. Large values suppress springback deformation until very near the termination time, making convergence during the first few steps easy. Small values may not stabilize the solution enough to allow equilibrium iterations to converge.

***CONTROL_IMPLICIT_STATIC_CONDENSATION_{OPTION}**

Available options include:

<BLANK>

BINARY

Purpose: Request static condensation of a part to build a reduced linearized model for later computation with *ELEMENT_DIRECT_MATRIX_INPUT. Optionally the analysis can continue using the linearization for the current analysis.

Note: Implicit Static Condensation is not supported in MPP. Please use *CONTROL_IMPLICIT_MODES.

| | | | | | | | | |
|----------|---------|---------|---------|---------|----------|----------|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | SC_FLAG | SC_NSID | SC_PSID | SE_MASS | SE_STIFF | SE_INERT | | |
| Type | I | I | I | C | C | C | | |
| Default | 0 | 0 | 0 | | | | | |

| | | | | | | | | |
|----------|-------------|---|---|---|---|---|---|---|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | SE_FILENAME | | | | | | | |
| Type | A80 | | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| SC_FLAG | Static Condensation Control Flag EQ.0: no static condensation will be performed EQ.1: create superelement representation based on static condensation. EQ.2: use static condensation to build a linearized representation for a part and use that linearized representation in the following analysis. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| SC_NSID | Node set ID for nodes to be preserved in the static condensation procedure. Required when SC_FLAG = 1. |
| SC_PSID | Part set ID for parts to be included in the static condensation procedure. When SC_FLAG = 1, SC_PSID can be used to specify a subset of the model with the default being the entire model. When SC_FLAG = 2, SC_PSID is required. SC_PSID = 0 implies that the entire model is condensed. |
| SE_MASS | Name of the superelement mass matrix. If left blank it is not generated. |
| SE_STIFF | Name of the superelement stiffness matrix. If left blank it is not generated. |
| SE_INERT | Name of the superelement inertia matrix, required for gravity loading applications of the superelement. If left blank it is not generated. |
| SE_FILENAME | If any of SE_MASS, SE_STIFF, or SE_INERT is blank then the second line is required and contains the file name for the superelement. |

Remarks:

To use this feature, an implicit analysis must be requested using IMFLAG = 1 on *CONTROL_IMPLICIT_GENERAL, and a non-zero termination time must be specified on *CONTROL_TERMINATION. A double precision version of LS-DYNA should be used for best accuracy. The superelement model is written to file SE_FILENAME.

Static condensation is the reduction of the global stiffness and mass matrices to a specified sets of rows and columns associated with the nodes in the node set SC_NSID. The first and second node set attribute parameters can be optionally used to restrict the translational and rotational degrees of freedom for which modes are requested, respectively, according to the following syntax:

Node set attribute parameters DA1 and A1: translational degree of freedom codes

Node set attribute parameters DA2 and A2: rotational degree of freedom codes

| <u>Code</u> | <u>Modes Computed</u> |
|-------------|------------------------------|
| 0 | (See note below.) |
| 1 | X degree of freedom only |
| 2 | Y degree of freedom only |
| 3 | Z degree of freedom only |
| 4 | X, Y degrees of freedom only |
| 5 | Y, Z degrees of freedom only |
| 6 | X, Z degrees of freedom only |
| 7 | X, Y, Z degrees of freedom |

Setting both node set attributes to zero is equivalent to setting both node set attributes to 7 (X, Y, and Z for translational and rotational degrees of freedom).

If one node set attribute is nonzero (codes 1 to 7) and the other node set attribute is zero, then the zero attribute means NO degrees of freedom are considered. For example, if DA1 = 2 and DA2 = 0, then only the Y-translational degree of freedom modes are calculated.

The user can create the superelement representation of the reduced model by specifying the SE_MASS, SE_STIFF, SE_INERT and SE_FILENAME fields. This implementation does not include SE_DAMP. The file, by default is written in the Nastran DMIG file format and can be used as input to *ELEMENT_DIRECT_MATRIX_INPUT. The keyword option BINARY can be used to create a binary representation for the superelement which can be used with *ELEMENT_DIRECT_MATRIX_INPUT_BINARY to reduce the file size.

Static Condensation is equivalent to using only constraint modes with *CONTROL_IMPLICIT_MODES. Static Condensation does have the ability to continue the analysis using the linear representation for a part set.

***CONTROL_IMPLICIT_TERMINATION**

Purpose: Specify termination criteria for implicit transient simulations.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|-------|-------|-------|-------|--------|---|
| Variable | DELTAU | DELTA1 | KETOL | IETOL | TETOL | NSTEP | ABSTOL | |
| Type | F | F | F | F | F | I | F | |
| Default | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 3 | 0.0 | |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| DELTAU | <p>Terminate based on relative total displacement in the Euclidean norm.</p> <p>GT.0.0: terminate when displacement in the Euclidean norm for last time step relative to the total displacement in the Euclidean norm is less than DELTAU.</p> |
| DELTA1 | <p>Terminate based on relative total displacement in the max norm.</p> <p>GT.0.0: terminate when displacement in the max norm for last time step relative to the total displacement in the max norm is less than DELTAU.</p> |
| KETOL | <p>Terminate based on kinetic energy</p> <p>GT.0.0: terminate when kinetic energy drops below KETOL for NSTEP consecutive implicit time steps.</p> |
| IETOL | <p>Terminate based on internal energy</p> <p>GT.0.0: terminate when internal energy drops below IETOL for NSTEP consecutive implicit time steps.</p> |
| TETOL | <p>Terminate based on total energy</p> <p>GT.0.0: terminate when total energy drops below TETOL for NSTEP consecutive implicit time steps.</p> |
| NSTEP | <p>Number of steps used in the early termination tests for kinetic, internal, and total energy.</p> |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| ABSTOL | Terminate based on absolute total displacement in the Euclidean norm. GT.0.0: terminate when displacement in the Euclidean norm for last time step is less than ABSTOL. |

Remarks:

For some implicit applications it is useful to terminate when there is no change in displacement or low energy. This keyword provides the ability to specify such a stopping criteria to terminate the simulation prior to ENDTIM.

***CONTROL_MAT**

Purpose: Define global control parameters for material model related properties.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | MAEF | | | | | | | |
| Type | I | | | | | | | |
| Default | 0 | | | | | | | |

VARIABLE**DESCRIPTION**

MAEF

Failure options:

EQ.0: all *MAT_ADD_EROSION definitions are active.

EQ.1: switch off all *MAT_ADD_EROSION definitions globally. This feature is useful for larger models where removing the *MAT_ADD_EROSION cards is inconvenient.

***CONTROL_MPP**

Purpose: Set control parameters for MPP specific features.

- *CONTROL_MPP_CONTACT_GROUPABLE
- *CONTROL_MPP_DECOMPOSITION_ARRANGE_PARTS
- *CONTROL_MPP_DECOMPOSITION_AUTOMATIC
- *CONTROL_MPP_DECOMPOSITION_BAGREF
- *CONTROL_MPP_DECOMPOSITION_CHECK_SPEED
- *CONTROL_MPP_DECOMPOSITION_CONTACT_DISTRIBUTE
- *CONTROL_MPP_DECOMPOSITION_CONTACT_ISOLATE
- *CONTROL_MPP_DECOMPOSITION_DISABLE_UNREF_CURVES
- *CONTROL_MPP_DECOMPOSITION_DISTRIBUTE_ALE_ELEMENTS
- *CONTROL_MPP_DECOMPOSITION_DISTRIBUTE_SALE_ELEMENTS
- *CONTROL_MPP_DECOMPOSITION_DISTRIBUTE_SPH_ELEMENTS
- *CONTROL_MPP_DECOMPOSITION_ELCOST
- *CONTROL_MPP_DECOMPOSITION_FILE
- *CONTROL_MPP_DECOMPOSITION_METHOD
- *CONTROL_MPP_DECOMPOSITION_NUMPROC
- *CONTROL_MPP_DECOMPOSITION_OUTDECOMP
- *CONTROL_MPP_DECOMPOSITION_PARTS_DISTRIBUTE
- *CONTROL_MPP_DECOMPOSITION_PARTSET_DISTRIBUTE
- *CONTROL_MPP_DECOMPOSITION_RCBLOG
- *CONTROL_MPP_DECOMPOSITION_SCALE_CONTACT_COST
- *CONTROL_MPP_DECOMPOSITION_SCALE_FACTOR_SPH
- *CONTROL_MPP_DECOMPOSITION_SHOW

*CONTROL_MPP_DECOMPOSITION_TRANSFORMATION
*CONTROL_MPP_IO_LSTC_REDUCE
*CONTROL_MPP_IO_NOBEAMOUT
*CONTROL_MPP_IO_NOD3DUMP
*CONTROL_MPP_IO_NODUMP
*CONTROL_MPP_IO_NOFAIL
*CONTROL_MPP_IO_NOFULL
*CONTROL_MPP_IO_SWAPBYTES
*CONTROL_MPP_PFILE

***CONTROL_MPP_CONTACT_GROUPABLE**

Purpose: Allow for global specification that the GROUPABLE algorithm should be enabled/disabled for contacts when running MPP.

| | | | | | | | | |
|----------|------|---|---|---|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | GRP | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

VARIABLE

DESCRIPTION

GRP

The sum of these available options (in any combination that makes sense):

- 1: Turn on GROUPABLE for all non-tied contacts
- 2: Turn on GROUPABLE for all tied contacts
- 4: Turn off GROUPABLE for all non-tied contacts
- 8: Turn off GROUPABLE for all tied contacts

Remarks:

The GROUPABLE algorithm is an alternate MPP communication algorithm for various single surface (including AUTOMATIC_GENERAL), nodes_to_surface, and surface_to_surface contacts. This groupable algorithm does not support all contact options, including SOFT = 2, ERODING, and MORTAR, and is still under development. It can be significantly faster and scale better than the normal algorithm when there are more than two or three applicable contact types defined in the model. Its intent is to speed up the contact processing but not to change the behavior of the contact.

This keyword will override any setting of the GRPABLE parameter on the *CONTACT_..._MPP card, and is intended as a way to quickly experiment with this feature. The equivalent pfile option is "contact { groupable GRP }" where GRP is an integer as described above.

*CONTROL

*CONTROL_MPP_DECOMPOSITION_ARRANGE_PARTS

*CONTROL_MPP_DECOMPOSITION_ARRANGE_PARTS_OPTION

Purpose: Allow users to distribute certain part(s) to all processors or to isolate certain part(s) in a single processor. This keyword supports multiple entries. Each entry is processed as a separate region for decomposition.

When this keyword is part of an included file and the **LOCAL** option is given, the decomposition will be done in the coordinate system of the included file, which may be different from the global system, if the file is included using the ***INCLUDE_TRANSFORM** keyword.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-------|-------|---|---|---|---|
| Variable | ID | TYPE | NPROC | FRSTP | | | | |
| Type | I | I | I | I | | | | |
| Default | none | none | None | None | | | | |

VARIABLE

DESCRIPTION

| | |
|-------|---|
| ID | Part ID/Part set ID |
| TYPE | EQ.0: Part ID to be distributed to all processors EQ.1: Part Set ID to be distributed to all processors EQ.10: Part ID to be lumped into one processor EQ.11: Part Set ID to be lumped into one processor EQ.20: Part ID to be lumped into one processor with MPP load balanced EQ.21: Part Set ID to be lumped into one processor with MPP load balanced. |
| NPROC | Used only for TYPE equal to 0 or 1. Number of processors will be used for decomposition and this Part ID/Part set ID will be distributed to NPROC of processors. |
| FRSTP | Used only for TYPE equal to 0 or 1. Starting MPP rank ID(rank starts from 0). |

Remarks:

Each line of this option will be treated as a region for the decomposition. Therefore the equivalent method is pfile will be different for part and partset as shown below.

Part: region { parts PID nproc NPROC FRSTP }

Part set: region { partsets PSID nproc NPROC FRSTP }

Part: region { parts PID lumped }

Part set: region { partsets PSID lumped }

Part: region { parts PID together }

Part set: region { partsets PSID together }

***CONTROL_MPP_DECOMPOSITION_AUTOMATIC**

Purpose: Instructs the program to apply a simple heuristic to try to determine the proper decomposition for the simulation.

There are no input parameters. The existence of this keyword triggers the automated decomposition. This option should not be used if there is more than one occurrence of any of the following options in the model:

*INITIAL_VELOCITY

*CHANGE_VELOCITY

*BOUNDARY_PRESCRIBED_MOTION

And the following control card must not be used:

*CONTROL_MPP_DECOMPOSITION_TRANSFORMATION

For the general case, it is recommended that you specify the proper decomposition using the command *CONTROL_MPP_DECOMPOSITION_TRANSFORMATION instead.

***CONTROL_MPP_DECOMPOSITION_BAGREF**

Purpose: With this card LS-DYNA performs decomposition according to the airbag's reference geometry, rather than the folded geometry.

Other than BAGID values this card takes no input parameters. The initial geometry may lead to a poor decomposition once the bag is deployed. This option will improve load balancing for the fully deployed geometry.

Optional card(s) for selected reference geometry ID

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|--------|--------|--------|--------|--------|--------|
| Variable | BAGID1 | BAGID2 | BAGID3 | BAGID4 | BAGID5 | BAGID6 | BAGID7 | BAGID8 |
| Type | I | I | I | I | I | I | I | I |
| Default | none |

| VARIABLE | DESCRIPTION |
|--------------------|--|
| BAGID _i | ID defined in *AIRBAG_REFERENCE_GEOMETRY_ID or *AIRBAG_SHELL_REFERENCE_GEOMETRY_ID |

Bags specified in the optional cards will be decomposed based on the reference geometry. If there is no card given, *all* bags will be decomposed by their reference geometry.

Remarks:

Command in partition file (pfile): BAGREF. The option for selecting particular airbags is only available when using keyword input.

***CONTROL**

***CONTROL_MPP_DECOMPOSITION_CHECK_SPEED**

***CONTROL_MPP_DECOMPOSITION_CHECK_SPEED**

Purpose: Modifies the decomposition depending on the relative speed of the processors involved.

There are no input parameters. Use of this keyword activates a short floating point timing routine to be executed on each processor. The information gathered is used during the decomposition, with faster processors being given a relatively larger portion of the problem. This option is not recommended on homogeneous systems.

***CONTROL_MPP_DECOMPOSITION_CONTACT_DISTRIBUTE** ***CONTROL**

***CONTROL_MPP_DECOMPOSITION_CONTACT_DISTRIBUTE_{OPTION}**

Purpose: Ensures that the indicated contact interfaces are distributed across all processors, which can lead to better load balance for large contact interfaces. If this appears in an included file and the LOCAL option is used, the decomposition will be done in the coordinate system of the included file, which may be different from the global system if the file is included through *INCLUDE_TRANSFORM.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|---|---|---|
| Variable | ID1 | ID2 | ID3 | ID4 | ID5 | | | |
| Type | I | I | I | I | I | | | |
| Default | none | none | none | none | none | | | |

VARIABLE

DESCRIPTION

ID1

First contact interface ID to distribute. If no contact ID's are specified, the number given here corresponds to the order of the interfaces as they appear in the input, with the first being 1.

ID2, ID3,
ID4, ID5

Remaining interfaces ID's to distribute.

Remarks:

Up to 5 contact interface ID's can be specified. The decomposition is modified as follows: First, all the elements involved in the first contact interface are decomposed across all the processors. Then all the elements involved in the second contact interface (excluding any already assigned to processors) are distributed, and so on. After all the contact interfaces given are processed, the rest of the input is decomposed in the normal manner. This will result in each processor having possibly several disjoint portions of the input assigned to it, which will increase communications somewhat. However, this can be offset by improved load balance for the contact. It is generally recommended that at most one or two interfaces be specified, and then only if they are of substantial size relative to the whole problem.

*CONTROL

*CONTROL_MPP_DECOMPOSITION_CONTACT_ISOLATE

*CONTROL_MPP_DECOMPOSITION_CONTACT_ISOLATE

Purpose: Ensures that the indicated contact interfaces are isolated on a single processor, which can lead to decreased communication.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|---|---|---|
| Variable | ID1 | ID2 | ID3 | ID4 | ID5 | | | |
| Type | I | I | I | I | I | | | |
| Default | none | none | none | none | none | | | |

VARIABLE

DESCRIPTION

ID1

First contact interface ID to isolate. If no contact ID's are specified, the number given here corresponds to the order of the interfaces as they appear in the input, with the first being 1.

ID2, ID3,
ID4, ID5

Remaining interfaces ID's to isolate.

Remarks:

Up to 5 contact interfaces can be specified. The decomposition is modified as follows: First, all the elements involved in the first contact interface ID are assigned to the first processor. Then all the elements involved in the second contact interface ID (excluding any already assigned to processors) are assigned to the next processor, and so on. After all the contact interfaces given are processed, the rest of the input is decomposed in the normal manner. This will result in each of the interfaces being processed on a single processor. For small contact interfaces this can result in better parallelism and decreased communication.

***CONTROL_MPP_DECOMPOSITION_DISABLE_UNREF_CURVES *CONTROL**

***CONTROL_MPP_DECOMPOSITION_DISABLE_UNREF_CURVES**

Purpose: Disable unreferenced time dependent load curves for the following keywords:

*BOUNDARY_PRESCRIBED_MOTION_NODE

*LOAD_NODE

*LOAD_SHELL_ELEMENT

*LOAD_THERMAL_VARIABLE_NODE

The details of this operation are reported in each processor's scratch scr#### file. This will skip the curve evaluation on each cycle, and improve the parallel efficiency.

Remarks:

Command in partition file (pfile): DUNREFLC.

***CONTROL_MPP_DECOMPOSITION_DISTRIBUTE_ALE_ELEMENTS**

Purpose: Ensures ALE elements are evenly distributed to all processors.

There are no input parameters and the card below is optional. ALE elements usually have a larger computational cost than other element types, and it is better to distribute them to all CPUs for better load balance. This keyword causes DYNA/MPP to extract ALE parts from the input and then evenly distribute them to all the processors.

FSI/ALE Mesh Card. This card is optional.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---------|---|---|---|---|---|---|---|
| Variable | OVERLAP | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

VARIABLE**DESCRIPTION**

OVERLAP

For FSI models where structures are inside ALE meshes (see *CONSTRAINED_LAGRANGE_IN_SOLID), flag to decompose the structure and ALE domains together instead of first the structure and then the ALE (see [Remark 2](#)).

EQ.0: Off

EQ.1: On

Remarks:

1. **Partition File.** Command in partition file (pfile): ALEDIST.
2. **ALE/FSI Overlap.** Most of the processors will have to deal with MPP subdomains from the structure and ALE meshes: a portion of the ALE computational domain and a portion of the structure meshes. The default decomposition (first divide the structures, then ALE) does not always overlap these subdomains. The more they overlap, the less the MPP communications due to the coupling cost. Cutting the ALE and structure meshes together allows their MPP subdomains to be as inclusive as possible.

***CONTROL_MPP_DECOMPOSITION_DISTRIBUTE_SPH_ELEMENTS**

Purpose: Ensures SPH elements are evenly distributed to all processors

There are no input parameters. SPH elements usually have higher computational cost than other type of elements and it is better to distribute them to all CPU for better load balance. The existence of this keyword causes DYNA/MPP to extract SPH parts from input and then evenly distributed to all processors.

Remarks:

Command in partition file (pfile): SPHDIST.

*CONTROL

*CONTROL_MPP_DECOMPOSITION_ELCOST

*CONTROL_MPP_DECOMPOSITION_ELCOST

Purpose: Instructs the program to use a hardware specific element cost weighting for the decomposition

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|---|---|---|---|---|---|
| Variable | ITYPE | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

VARIABLE

DESCRIPTION

ITYPE

Hardware specific cost profile.

EQ.1: Fujitsu PrimePower

EQ.2: Intel IA 64, AMD Opteron

EQ.3: Intel Xeon 64

EQ.4: General profile

Remarks:

Command in partition file (pfile): elcost itype.

***CONTROL_MPP_DECOMPOSITION_FILE**

Purpose: Allow for pre-decomposition and a subsequent run or runs without having to do the decomposition.

| | | | | | | | | |
|----------|------|---|---|---|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | NAME | | | | | | | |
| Type | A80 | | | | | | | |
| Default | none | | | | | | | |

VARIABLE

DESCRIPTION

NAME

Name of a file containing (or to contain) a decomposition record.

Remarks:

If the indicated file does not exist, it is created with a copy of the decomposition information from this run. If the file exists, it is read and the decomposition steps can be skipped. The original run that created the file must be for a number of processors that is a multiple of the number of processors currently being used. Thus, a problem can be decomposed once for, say, 48 processors. Subsequent runs are then possible on any number that divides 48: 1, 2, 3, 4, 6, etc. Since the decomposition phase generally requires more memory than execution, this allows large models to be decomposed on one system and run on another (provided the systems have compatible binary formats). The file extension “.pre” is added automatically.

*CONTROL

*CONTROL_MPP_DECOMPOSITION_METHOD

*CONTROL_MPP_DECOMPOSITION_METHOD

Purpose: Specify the decomposition method to use.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | NAME | | | | | | | |
| Type | A80 | | | | | | | |
| Default | RCB | | | | | | | |

VARIABLE

DESCRIPTION

NAME

Name of the decomposition method to use. There are currently two options:

EQ."RCB": recursive coordinate bisection

EQ."GREEDY": a simple heuristic method

In almost all cases the RCB method is superior and should be used.

***CONTROL_MPP_DECOMPOSITION_NUMPROC**

Purpose: Specify the number of processors for decomposition.

| | | | | | | | | |
|----------|------|---|---|---|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | N | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

VARIABLE

DESCRIPTION

N

Number of processors for decomposition.

Remarks:

This is used in conjunction with the CONTROL_MPP_DECOMPOSITION_FILE command to allow for later runs on different numbers of processors. By default, the decomposition is performed for the number of processors currently being used. However, a different value can be specified here. If $N > 1$ and only one processor is currently being used, the decomposition is done and then the program terminates. If N is *not* a multiple of the current number of processors, then it is ignored the execution proceeds with the current number of processors. Otherwise, the decomposition is performed for N processors, and the execution continues using the current number of processors.

***CONTROL_MPP_DECOMPOSITION_OUTDECOMP**

Purpose: Instructs the program to output element's ownership data to file for post-processor to show state data from different processors.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | TYPE | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

VARIABLE**DESCRIPTION**

ITYPE

Sets the format for the output file.

EQ.1: database in LS-PrePost format:

decomp_parts.lsprepost

EQ.2: database in animator format:

decomp_parts.ses

Remarks:

1. **PFILE.** Command in partition file (pfile): OUTDECOMP ITYPE.
2. **LS-PrePost.** When ITYPE is set to 1, the elements assigned to any particular core can be viewed and animated by LS-PrePost by (1) reading the d3plot data, and then (2) selecting *Models* → *Views* → *MPP* → *Load* → *decomp_parts.lsprepost*.

***CONTROL_MPP_DECOMPOSITION_PARTS_DISTRIBUTE_{OPTION}**

Purpose: Distribute the parts given by this keyword to all processors before the decomposition for the rest of the model is performed. If this appears in an included file and the LOCAL option is used, the decomposition will be done in the coordinate system of the included file, which may be different from the global system if the file is included via *INCLUDE_TRANSFORM.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | ID1 | ID2 | ID3 | ID4 | ID5 | ID6 | ID7 | ID8 |
| Type | I | I | I | I | I | I | I | I |
| Default | none |

VARIABLE**DESCRIPTION**

ID1, ID2,
ID3, ...

For each ID:

GT.0: ID is a part number.

LT.0: |ID| is a part set number.

All parts defined in this card will be treated as a single region to be decomposed.

Remarks:

1. **Decomposition.** Up to 1000 parts/part sets can be specified. The decomposition is modified as follows: the elements involved in the given parts are put into a separate domain from rest of the model and then distributed to all processors to balance their computational cost. Then the remainder of the model will be distributed in the usual way.
2. **PFILE.** This is equivalent to the pfile command (for example, if ID1 - ID3 are part IDs and ID4 - ID6 are part set IDs):

```
decomp { region { parts ID1 ID2 ID3 or partsets ID4 ID5 ID6 } }
```

The part set IDs, however, are positive when used in the pfile.

***CONTROL *CONTROL_MPP_DECOMPOSITION_PARTSET_DISTRIBUTE**

***CONTROL_MPP_DECOMPOSITION_PARTSET_DISTRIBUTE_{OPTION}**

Purpose: Distribute the part sets given in this option to all processors before the decomposition for the remainder of the model is performed. If this appears in an included file and the LOCAL option is given, the decomposition will be done in the coordinate system of the included file, which may be different from the global system if the file is included via *INCLUDE_TRANSFORM.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | ID1 | ID2 | ID3 | ID4 | ID5 | ID6 | ID7 | ID8 |
| Type | I | I | I | I | I | I | I | I |
| Default | none |

VARIABLE

DESCRIPTION

ID1, ID2,
ID3, ...

Part Set ID to be distributed. All parts in ID1 will be shared across all processors. Then all parts in ID2 will be distributed, and so on.

Remarks:

Any number of part sets can be specified. Each part set is distributed across all processors, in the order given. The order may be significant if, in particular, a part ID is in more than one set. Distribution of these parts is done before any decomposition specifications given in the pfile.

***CONTROL_MPP_DECOMPOSITION_RCBLOG**

Purpose: Causes the program to record decomposition information in the indicated file, for use in subsequent analyses.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|---|---|---|---|---|---|---|
| Variable | FILENAME | | | | | | | |
| Type | A80 | | | | | | | |
| Default | none | | | | | | | |

VARIABLE

DESCRIPTION

FILENAME

Name of output file where decomposition history will be recorded. This file can be used as the pfile for later analyses.

Remarks:

Command in parallel option file (pfile): rcblog filename.

***CONTROL *CONTROL_MPP_DECOMPOSITION_SCALE_CONTACT_COST**

***CONTROL_MPP_DECOMPOSITION_SCALE_CONTACT_COST**

Purpose: Instructs the program to apply a scale factor to the list of contacts to change the partition weight for the decomposition.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | SF | ID1 | ID2 | ID3 | ID4 | ID5 | ID6 | ID7 |
| Type | F | I | I | I | I | I | I | I |
| Default | none |

VARIABLE

DESCRIPTION

SF

Scale factor for the contact segments listed in the interface ID.

ID1, ID2, ...

interfaces ID's to be considered for scaling. Include second card if necessary.

Remarks:

Up to 15 contact interfaces ID can be specified. The decomposition is modified by applying this scale factor to the default computational cost of elements for the given contact interface ID.

Command in partition file (pfile): CTCOST ID1, ID2, ..., SF.

***CONTROL_MPP_DECOMPOSITION_SCALE_FACTOR_SPH**

Purpose: Instructs the program to apply a scale factor to SPH elements to change the partition weight for the decomposition.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | SF | | | | | | | |
| Type | F | | | | | | | |
| Default | none | | | | | | | |

VARIABLE

DESCRIPTION

SF

Scale factor

Remarks:

Command in partition file (pfile): SPHSF SF.

***CONTROL_MPP_DECOMPOSITION_SHOW**

Purpose: The keyword writes the final decomposition to the d3plot database. There are no input parameters.

This keyword causes MPP LS-DYNA to terminate immediately after the decomposition phase without performing an analysis. The resulting d3plot database is designed to allow visualization of the decomposition by making each part correspond to the group of solids, shells, beams, thick shells, or SPH particles assigned to a particular processor. For example, in a model that includes various element types including solids, part 1 corresponds to the solid elements assigned to processor 1, part 2 corresponds to the solid elements assigned to processor 2, and so on.

This command can be used in conjunction with the *CONTROL_MPP_DECOMPOSITION_NUMPROC command to run on one processor and produce a d3plot file to visualize the resulting decomposition for the number of processors specified in *CONTROL_MPP_DECOMPOSITION_NUMPROC.

***CONTROL_MPP_DECOMPOSITION_TRANSFORMATION**

Purpose: Specifies transformations to apply to modify the decomposition.

There are 10 different kinds of decomposition transformations available. For a detailed description of each, see Appendix O the LS-DYNA MPP user guide.

The data cards for this keyword consist of transformation operations. Each operation, depending on its type, involves either one or two additional cards. The input deck may include an arbitrary number of transformations with the next keyword, "*" card, terminating this input.

Transformation Card 1. For each transformation this card is required.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|-----|-----|-----|-----|-----|---|
| Variable | TYPE | V1 | V2 | V3 | V4 | V5 | V6 | |
| Type | A10 | F | F | F | F | F | F | |
| Default | none | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | |

Transformation Card 2. Additional card for TYPE set to one of VEC3, C2R, S2R, MAT.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|---|---|---|---|---|
| Variable | V7 | V8 | V9 | | | | | |
| Type | F | F | F | | | | | |
| Default | 0.0 | 0.0 | 0.0 | | | | | |

VARIABLE

DESCRIPTION

TYPE Which transformation to apply. The allowed values are RX, RY, RZ, SX, SY, SZ, VEC3, C2R, S2R, and MAT.

V1 - V9 For type set to either RX, RY, RZ, SX, SY, or SZ:
The parameter V1 gives either the angle of rotation (RX, RY, RZ) or the magnitude for the scaling (SX, SY, SZ). The remaining parameters are ignored.

*CONTROL

*CONTROL_MPP_DECOMPOSITION_TRANSFORMATION

| VARIABLE | DESCRIPTION |
|----------|-------------|
|----------|-------------|

For type set to either VEC3, C2R, S2R, or MAT:

All parameters are used. See the appendix for the "pfile."

Remarks:

When using scale factors (SX, SY, SZ), specify a non-zero scale factor; if left blank, it will be set to use 0.0.

***CONTROL_MPP_IO_LSTC_REDUCE**

Purpose: Use LSTC's own reduce routine to get consistent summation of floating point data among processors. There are no input parameters.

Remarks:

Command in partition file (pfile): lstc_reduce.

***CONTROL_MPP_IO_NOBEAMOUT**

Purpose: Suppress beam, shell, and solid element failure messages in the d3hsp and message files. There are no parameters for this keyword.

Remarks:

Command in parallel option file (pfile): nobeamout.

***CONTROL_MPP_IO_NOD3DUMP**

Purpose: Suppresses the output of all dump files.

There are no input parameters. The existence of this keyword causes the d3dump and runrsf file output routines to be skipped.

***CONTROL_MPP_IO_NODUMP**

Purpose: Suppresses the output of all dump files and full deck restart files.

There are no input parameters. The existence of this keyword causes the d3dump and runrsf file output routines to be skipped. It also suppresses output of the full deck restart file d3full.

***CONTROL_MPP_IO_NOFULL**

Purpose: Suppresses the output of the full deck restart files.

There are no input parameters. The existence of this keyword suppresses the output of the full deck restart file d3full.

***CONTROL_MPP_IO_SWAPBYTES**

Purpose: Swap bytes on some of the output files.

There are no input parameters. The existence of this keyword causes the d3plot file and the "interface component analysis" file to be output with bytes swapped. This is to allow further processing of data on a different machine that has big endian vs. little endian incompatibilities compared to the system on which the analysis is running.

***CONTROL_MPP_MATERIAL_MODEL_DRIVER**

Purpose: Enable this feature in MPP mode. To allow MPP reader to pass the input phase even without any nodes and elements but using only one processor.

***CONTROL_MPP_PFILE**

Purpose: Provide keyword support for the MPP “p=” pfile options

All lines of input up to the next keyword card will be copied to a temporary file which is effectively pre-pended to the “p=” file given on the command line (even if no such file is given). This allows all options available via the “p=” file to be specified in the keyword input. The only restriction is that pfile directives in the “directory” section are not available, as those must be processed before the keyword input file is read. See the “LS-DYNA MPP User Guide” in the appendix for details of the available pfile commands and their syntax.

***CONTROL_NONLOCAL**

Purpose: Allocate additional memory for *MAT_NONLOCAL option.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | MEM | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

VARIABLE

DESCRIPTION

MEM

This parameter is no longer used and any value input will be ignored. Memory is allocated dynamically as needed.

*CONTROL

*CONTROL_OUTPUT

*CONTROL_OUTPUT

Purpose: Set miscellaneous output parameters. This keyword does not control the information that is written into the binary databases, such as the stress and strain tensors. For the latter, see the keyword *DATABASE_EXTENT_BINARY.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

| Default | 0 | 0 | 0 | | | | | |

VARIABLE**DESCRIPTION**

NPOPT

Print suppression during input phase flag for the d3hsp file:

EQ.0: no suppression,

EQ.1: nodal coordinates, element connectivities, rigid wall definitions, nodal SPCs, initial velocities, initial strains, adaptive constraints, and SPR2/SPR3 constraints are not printed.

NEECHO

Print suppression during input phase flag for echo file:

EQ.0: all data printed,

EQ.1: nodal printing is suppressed,

EQ.2: element printing is suppressed,

EQ.3: both nodal and element printing is suppressed.

NREFUP

Flag to update reference node coordinates for beam formulations 1, 2, and 11. This option requires that each reference node is unique to the beam:

EQ.0: Do not update reference node.

EQ.1: Update reference node. This update is required for proper visualization of the beam cross-section orientation in LS-PrePost beyond the initial ($t = 0.0$) plot state. NREFUP does not affect the internal updating of the beam cross-section orientation in LS-DYNA.

IACCOP

Flag to average or filter nodal accelerations output to file nodout and the time history database d3thdt:

EQ.0: no average (default),

EQ.1: averaged between output intervals,

EQ.2: accelerations for each time step are stored internally and

| VARIABLE | DESCRIPTION |
|-----------------|--|
| OPIFS | <p>then filtered over each output interval using a filter from General Motors [Sala, Neal, and Wang, 2004] based on a low-pass Butterworth frequency filter. See also [Neal, Lin, and Wang, 2004]. DT2MS in *CONTROL_-TIMESTEP must be set to a negative value when IAC-COP = 2 so that the maximum possible number of time steps for an output interval is known and adequate memory can be allocated.</p> <p>Output time interval for interface file written per *INTERFACE_-COMPONENT_option.</p> |
| IPNINT | <p>Flag controlling output of initial time step sizes for elements to d3hsp:</p> <p>EQ.0: 100 elements with the smallest time step sizes are printed.</p> <p>EQ.1: Time step sizes for all elements are printed.</p> <p>GT.1: IPNINT elements with the smallest time step sizes are printed.</p> |
| IKEDIT | <p>Problem status report interval steps to the d3hsp file. This flag is ignored if the glstat file is written; see *DATABASE_GLSTAT.</p> |
| IFLUSH | <p>Number of time steps interval for flushing I/O buffers. The default value is 5000. If the I/O buffers are not emptied and an abnormal termination occurs, the output files can be incomplete. The I/O buffers for restart files are emptied automatically whenever a restart file is written so these files are not affected by this option.</p> |
| IPRTF | <p>Default print flag for rbdout and matsum files. This flag defines the default value for the print flag which can be defined in the part definition section; see *PART. This option is meant to reduce the file sizes by eliminating data which is not of interest.</p> <p>EQ.0: write part data into both matsum and rbdout</p> <p>EQ.1: write data into rbdout file only</p> <p>EQ.2: write data into matsum file only</p> <p>EQ.3: do not write data into rbdout and matsum</p> |
| IERODE | <p>Output eroded internal and kinetic energy into the matsum file. Also, output to the matsum file under the heading of part ID 0 the</p> |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | <p>kinetic energy from nonstructural mass, lumped mass elements and lumped inertia elements.</p> <p>EQ.0: do not output extra data</p> <p>EQ.1: output the eroded internal and kinetic energy</p> |
| TET10S8 | <p>Output ten connectivity nodes for the 10-node solid tetrahedral (solid formulations 16/17) and the eight connectivity nodes for the 8-node shell (shell formulation 23) into the d3plot database. The current default is set to 2 since this change in the database may make the data unreadable for many popular post-processors and older versions of LS-PrePost.</p> <p>EQ.1: write the full node connectivity into the d3plot database</p> <p>EQ.2: write only the corner nodes of the elements into the d3plot database</p> |
| MSGMAX | <p>Maximum number of each error/warning message:</p> <p>GT.0: number of messages to screen output; all messages written to d3hsp/messag</p> <p>LE.0: number of messages to screen output and d3hsp/messag</p> <p>EQ.0: default, 50</p> |
| IPCURV | <p>Flag to output digitized curve data to messag and d3hsp files:</p> <p>EQ.0: off</p> <p>EQ.1: on</p> |
| GMDT | <p>Output interval for recorded motions from *INTERFACE_SSI_AUX</p> |
| IP1DBLT | <p>Output information of 1D (bar-type) seatbelt created for 2D (shell-type) seatbelt to sbtout.</p> <p>EQ.0: the analysis results of internally created 1D seatbelts are extracted and processed to yield the 2D belt information. The 2D belt information is stored in sbtout.</p> <p>EQ.1: the analysis results of internally created 1D retractors and slip rings are stored in sbtout. Belt load can be yielded by *DATABASE_CROSS_SECTION.</p> |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| EOCS | <p>elout Coordinate System: controls the coordinate system to be used when writing out shell data to the elout file. EOCS has no effect on eloutdet.</p> <p>EQ.0: default (local element coordinate system, or if an orthotropic material model and CMPFLG = 1, then material coordinate system)</p> <p>EQ.1: local element coordinate system</p> <p>EQ.2: global coordinate system</p> |
| TOLEV | <p>Timing Output Levels: controls the number of levels output in the timing summary at termination. The default is 2.</p> |
| NEWLEG | <p>New Legends: controls the format of the LEGEND section of various ASCII output files.</p> <p>EQ.0: use the normal format</p> <p>EQ.1: use the optional format with extra fields.</p> |
| FRFREQ | <p>Output frequency for failed element report in cycles. The default is to report the summary every cycle in which an element fails. If > 1, the summary will be reported every FRFREQ cycles whether an element fails that cycle or not, provided some element has failed since the last summary report. Individual element failure is still reported as it occurs.</p> |
| MINFO | <p>Output penetration information for mortar contact after each implicit step, not applicable in explicit analysis. See remarks on mortar contact on *CONTACT card.</p> <p>EQ.0: No information</p> <p>EQ.1: Penetrations reported for each contact interface.</p> |
| SOLSIG | <p>Flag to extrapolate stresses and other history variables for multi-integration point solids from integration points to nodes. These extrapolated nodal values replace the integration point values normally stored in d3plot. When a nonzero SOLSIG is invoked, NINTSLD in *DATABASE_EXTENT_BINARY should be set to 8 as any other value of NINTSLD will result in only one value being reported for each element. Supported solid formulations are: -1, -2, 2, 3, 4, 18, 16, 17, and 23.</p> <p>EQ.0: No extrapolation.</p> |

| VARIABLE | DESCRIPTION |
|----------|--|
| | <p>EQ.1: Extrapolate the stress for linear materials only.</p> <p>EQ.2: Extrapolate the stress if plastic strain is zero.</p> <p>EQ.3: Extrapolate the stress always.</p> <p>EQ.4: Extrapolate all history variables.</p> <div style="border: 1px solid black; padding: 5px; margin: 10px 0;"> <p>NOTE: Do not use "Setting - Extrapolate" in LS-PrePost when this field, SOLSIG, is nonzero.</p> </div> |
| MSGFLG | <p>Flag for writing detailed error/warning messages to d3msg. MSGFLG has no effect on output of standard length error/warning messages; such messages are written to <code>messag</code> or <code>mes****</code>. NOTE: Most errors/warnings offer only standard length messages. Only a few also offer optional, detailed messages.</p> <p>EQ.0: Do not write detailed messages to d3msg.</p> <p>EQ.1: Write detailed messages to d3msg at the conclusion of the run. Each detailed message is written only once even in cases where the associated error or warning occurs multiple times.</p> |
| CDETOL | <p>Tolerance for output of *DEFINE_CURVE discretization warnings. After each curve is discretized, the resulting curve is evaluated at each of the original definition points, and the values compared. A warning will be issued for any curve where this comparison results in an error of more than $CDETOL/100 \times M$, where the curve specific value M is computed as the median of the absolute values of the non-zero curve values.</p> |
| PHSCHNG | <p>Message to <code>messag</code> file when materials 216, 217, and 218 change phase.</p> <p>EQ.0: (default) no message.</p> <p>EQ.1: The time and element ID are written.</p> |
| DEMDEN | <p>Output DEM density data to d3plot database.</p> <p>EQ.0: (default) no output.</p> <p>EQ.1: output data.</p> |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| ICRFILE | <p>Flag to output node sets and element sets used in computing secforc data; see *DATABASE_CROSS_SECTION_OPTION and *DATABASE_SECFORC. These sets are written in keyword format (*SET_...) and thus can be displayed using LS-PrePost. The assigned set IDs are the same as the ID of the cross-section.</p> <p>EQ.0: Do not write sets (default).</p> <p>EQ.1: Write a separate file for each cross-section called <code>cross_section_#</code> where # is the cross-section ID.</p> <p>EQ.2: Write sets for all cross-sections to a file called <code>cross_sections</code>.</p> |

***CONTROL_PARALLEL**

Purpose: Control parallel processing usage by defining the number of processors and invoking the optional consistency of the global vector assembly. This command applies only to shared memory parallel (SMP) LS-DYNA. It does not apply to distributed memory parallel (MPP) LS-DYNA.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|-------|------|---|---|---|---|
| Variable | NCPU | NUMRHS | CONST | PARA | | | | |
| Type | I | I | I | I | | | | |
| Default | 1 | 0 | 2 | 0 | | | | |
| Remarks | | 1 | 2 | 3 | | | | |

VARIABLE**DESCRIPTION**

NCPU

Number of cpus used.

(This parameter is disabled in 971 R5 and later versions. Set number of cpus using "ncpu =" on the execution line — see Execution Syntax section of Getting Started — or on the *KEYWORD line of the input.)

NUMRHS

Number of right-hand sides allocated in memory:

EQ.0: same as NCPU, always recommended,

EQ.1: allocate only one.

CONST

Consistency flag. (Including "ncpu = n " on the execution line or on the *KEYWORD line of input overrides CONST. The algebraic sign of n determines the consistency setting.)

EQ.1 or $n < 0$: on (recommended)EQ.2 or $n > 0$: off, for a faster solution (default).

| VARIABLE | DESCRIPTION |
|-----------------|---|
| PARA | Flag for parallel force assembly if $CONST = 1$. (Including "para =" on the execution line overrides PARA.) EQ.0: off EQ.1: on (see Remark 3) EQ.2: on (see Remark 3) |

Remarks:

1. **NUMHRS.** It is recommended to always set $NUMRHS = NCPU$ because then the force assembly is done in parallel which greatly improves the parallel performance. Setting $NUMRHS$ to one reduces storage by one right hand side vector for each additional processor after the first. If the consistency flag is active, that is, $CONST = 1$, $NUMRHS$ defaults to unity.
2. **Consistency.** For any given problem with the consistency option off, i.e., $CONST = 2$, slight differences in results are seen when running the same job multiple times with the same number of processors and also when varying the number of processors. Comparisons of nodal accelerations often show wide discrepancies; however, it is worth noting that the results of accelerometers often show insignificant variations due to the smoothing effect of the accelerometers which are generally attached to nodal rigid bodies.

The accuracy issues are not new and are inherent in numerical simulations of automotive crash and impact problems where structural bifurcations under compressive loads are common. This problem can be easily demonstrated by using a perfectly square thin-walled tubular beam of uniform cross section under a compressive load. Typically, every run on one processor that includes a minor input change (i.e., element or hourglass formulation) will produce dramatically different results in terms of the final shape, and, likewise, if the same problem is again run on a different brand of computer. If the same problem is run on multiple processors the results can vary dramatically from run to run WITH NO INPUT CHANGE. The problem here is due to the randomness of numerical round-off which acts as a trigger in a "perfect" beam.

Since summations will ($CONST = 2$) occur in a different order from run to run, the round-off is also random. The consistency flag, $CONST = 1$, provides for identical results (or nearly so) whether one, two, or more processors are used while running in the shared memory parallel (SMP) mode. This is done by requiring that all contributions to global vectors be summed in a precise order independently of the number of processors used. When checking for consistent results, nodal displacements or element stresses should be compared. The

NODOUT and ELOUT files should be digit to digit identical. However, the GLSTAT, SECFORC, and many of the other ASCII files will not be identical since the quantities in these files are summed in parallel for efficiency reasons and the ordering of summation operations are not enforced. The biggest drawback of this option is the CPU cost penalty which is at least 15 percent if $PARA = 0$ and is much less if $PARA = 1$ and 2 or more processors are used. Unless the $PARA$ flag is on (for non-vector processors), parallel scaling is adversely affected. The consistency flag does not apply to MPP parallel.

3. **PARA.** The $PARA$ flag set to 1 or 2 will cause the force assembly for the consistency option to be performed in parallel for the SMP version, so better scaling will be obtained. However, $PARA = 1$ will increase memory usage while $PARA = 2$ will not. This flag does not apply to the MPP version. If $PARA = 0$, $CONST = 0$, and $NUMRHS = NCPU$, the force assembly by default is done in parallel, but without consistency. The value of the flag may also be given by including “ $para = <value>$ ” on the execution line, and the value given in this manner will override the value of $PARA$ in $*CONTROL_PARALLEL$.

*CONTROL

*CONTROL_PORE_AIR

*CONTROL_PORE_AIR

Purpose: Set parameters for pore air pressure calculations.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---------|-------|--------|--------|---|---|---|---|
| Variable | AIR_RHO | AIR_P | ETERM | ANAMSG | | | | |
| Type | F | F | F | I | | | | |
| Default | none | none | endtim | 0 | | | | |

VARIABLE

DESCRIPTION

| | |
|---------|--|
| AIR_RHO | Density of atmospheric air, = 1.184 kg/m ³ at 25°C |
| AIR_P | Pressure of atmospheric air, = 101.325 kPa at 25°C |
| ETERM | Event termination time, default to ENDTIME of *CONTROL_TERMINATION |
| ANAMSG | Flag to turn off the printing of pore air analysis status message, including the analysis time, the node with the highest pressure change. EQ.0: Status messages are printed, the default value. EQ.1: Status messages are not printed |

***CONTROL_PORE_FLUID**

Purpose: Set parameters for pore water pressure calculations.

This control card is intended for soil analysis. However, other materials containing pore fluid could be treated by the same methods. The pore pressure capabilities invoked by this card are available in SMP and MPP versions of LS-DYNA, but are not available for implicit solutions. Furthermore, pore pressure capabilities are limited to a subset of 3D solid Lagrangian element formulations, including solid formulations 1, 2, 4, 10, and 15.

LS-DYNA uses Terzaghi's Effective Stress to model materials with pore pressure. The pore fluid and soil skeleton are assumed to occupy the same volume and to carry loads in parallel. Thus, the total stress in an element is the sum of the "effective stress" in the soil skeleton, plus the hydrostatic stress in the pore fluid. LS-DYNA calculates the "effective stress" with standard material models. The pore fluid treatment, then, is independent of material model. The pore pressure is calculated at nodes, and interpolated onto the elements. The pore fluid's hydrostatic stress is equal to the negative of the element pore pressure.

|----------|--------|---|---|---|---|---|---|---|
| Variable | ETFLAG | | | | | | | |
| Type | I | | | | | | | |
| Default | 0 | | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|---------|--|
| ATYPE | Analysis type for pore water pressure calculations (see Analysis Types): EQ.0: No pore water pressure calculation. EQ.1: Undrained analysis, EQ.2: Drained analysis, EQ.3: Time dependent consolidation (coupled), EQ.4: Consolidate to steady state (uncoupled), EQ.5: Drained in dynamic relaxation, undrained in transient, EQ.6: Same as 4 but do not check convergence, continue to end time. |
| WTABLE | Default z-coordinate of water table (where pore pressure is zero). |
| PF_RHO | Default density for pore water. |
| GRAV | Gravitational acceleration used to calculate hydrostatic pore water pressure. |
| PF_BULK | Default bulk modulus of pore fluid (stress units). |
| OUTPUT | Output flag controlling stresses to D3PLOT and D3THDT binary files: EQ.0: total stresses are output EQ.1: effective stresses are output, see Output |

| VARIABLE | DESCRIPTION |
|----------|---|
| TMF | Initial Time Magnification factor for seepage (ATYPE = 3,4 only). GT.0: Factor (can be used with automatic control, see TARG, FMIN, FMAX). LT.0: Load Curve ID (see *DEFINE_CURVE) giving Time Magnification Factor as a function of analysis time. |
| TARG | Target for maximum change of excess pore pressure at any node, per timestep. If the actual change falls below the target, the time factor for the seepage calculation will be increased (see Time Factoring). If zero, the constant value of TMF is used. If non-zero, TMF is taken as the initial factor. |
| FMIN | Minimum time factor for seepage calculation |
| FMAX | Maximum time factor for seepage calculation |
| FTIED | Analysis type for pore water pressure calculations (see Remark 1): EQ.0.0: Tied contacts act as impermeable membranes, EQ.1.0: Fluid may flow freely through tied contacts. |
| CONV | Convergence tolerance for ATYPE = 4. Maximum head change per time step at any node as measured in units of characteristic length, l . $l = \frac{p}{\rho g}$ where, ρ = pore fluid density, PF_RHO g = gravitational acceleration. |
| CONMAX | Maximum factor on permeability for ATYPE = -4 |
| ETERM | Event time termination (ATYPE = 3) |
| THERM | Thermal expansion: Volumetric strain per degree increase for undrained soil. |
| ETFLAG | Flag for interpretation of time (see Time Factoring): EQ.0: Time means analysis time, EQ.1: Time means event time. |

Analysis Types (see ATYPE):

1. **Undrained.** For analyses of the “undrained” type the pore fluid is trapped within the material. Volume changes result in pore pressure changes. This approximation is used to simulate the effect of rapidly-applied loads on relatively impermeable soil.
2. **Drained.** For analyses of the “drained” type the pore fluid is free to move within the material such that the user-defined pressure as a function of z-coordinate relationship is always maintained. This approximation is used to model high-permeability soils.
3. **Time-Dependent Consolidation.** For the analysis type “time dependent consolidation” pressure gradients cause pore fluid to flow through the material according to Darcy’s law:

$$v = \kappa \nabla(p + z),$$

where

v = fluid velocity vector
 κ = permeability
 p = pressure head
 z = z-coordinate.

Net inflow or outflow at a node leads to a theoretical volume gain or loss. The analysis is coupled, that is, any difference between actual and theoretical volume leads to pore pressure change, which in turn affects the fluid flow. The result is a prediction of response as a function of time.

4. **Steady-state consolidation.** For the analysis type “steady-state consolidation” an iterative method is used to calculate the steady-state pore pressure. The analysis is uncoupled, that is, only the final state is meaningful, not the response as a function of time.

Time Factoring:

Consolidation occurs over time intervals of days, weeks or months. To simulate this process using explicit time integration, a time factor is used. The permeability of the soil is increased by the time factor so that consolidation occurs more quickly. The output times in the D3PLOT and D3THDT files are modified to reflect the time factor. The factored time (“Event Time”) is intended to represent the time taken in the real-life consolidation process and will usually be much larger than the analysis time (the analysis time is the sum of the LS-DYNA timesteps). The time factor may be chosen explicitly (using TMF), but it is recommended to use automatic factoring instead. The automatic scheme adjusts the time factor according to how quickly the pore pressure is changing; usually at the start of consolidation the pore pressure changes quickly and

the time factor is low; the time factor increases gradually as the rate of pore pressure change reduces. Automatic time factoring is input by setting TARG (the target pore pressure head change per timestep) and maximum and minimum allowable time factors, for example TARG = 0.001 to 0.01 m head, FMIN = 1.0, FMAX = 10⁶. Optimum settings for these are model-dependent.

Loading, other input data from load curves, and output time-intervals on *DATABASE cards by default use the analysis time (for example, the *x*-axis of a load curve used for pressure loading is analysis time). When performing consolidation with automatic time-factoring, the relationship between analysis time and event time is unpredictable. Termination based on event time may be input using ETERM.

It may also be desired to apply loads as functions of event time rather than analysis time, since the event time is representative of the real-life process. By setting ETFLAG = 2, the time axis of all load curves used for any type of input as a function of time, and output intervals on *DATABASE cards, will be interpreted as event time. This method also allows consolidation to be used as part of a staged construction sequence – when ETFLAG = 2, the stages begin and end at the “real time” stage limits and input curves of pore pressure analysis type as a function of time may be used to enforce, for example, consolidation in some stages, and undrained behavior in others.

Output:

Five extra variables for solid elements are automatically written to the d3plot and d3thdt files when the model contains *CONTROL_PORE_FLUID, in addition to the NEIPH variables requested on *DATABASE_EXTENT_BINARY. The first of the five is the pore pressure in stress units; the second is the excess pore pressure, meaning actual minus hydrostatic pressure. These follow the NEIPH extra variables requested by the user, so for example if NEIPH = 3 then there will be a total of 8 extra variables in the d3plot and d3thdt files of which the fourth is pore pressure.

Further optional output to d3plot and d3thdt files is available for nodal pore pressure variables; see *DATABASE_PWP_OUTPUT.

For time-dependent and steady-state consolidation, information on the progress of the analysis is written to d3hsp file.

Remarks:

1. **Tied Contacts.** By default, the mesh discontinuity at a tied contact will act as a barrier to fluid flow. If the flag FTIED is set to 1.0, then pore fluid will be transmitted across tied nodes in tied contacts (*CONTACT_TIED_SURFACE_TO_SURFACE and *CONTACT_TIED_NODES_TO_SURFACE, including_

OFFSET and non-OFFSET types). This algorithm has an effect only when the analysis type of at least one of the contacting parts is 3, 4 or 6.

2. **Thermal.** Note that this property is for VOLUMETRIC strain increase. Typical thermal expansion coefficients are linear; the volumetric expansion will be three times the linear thermal expansion coefficient. Regular thermal expansion coefficients (e.g. on *MAT or *MAT_ADD_THERMAL_EXPANSION) apply to the soil skeleton and to drained parts. Pore pressure can be generated due to the difference of expansion coefficients of the soil skeleton and pore fluid.
3. **Part Associativity.** Pore pressure is a nodal variable, but analysis type and other pore pressure related inputs are properties of parts. When a node is shared by elements of different parts, and those parts have different pore pressure inputs, the following rules are followed to determine which part's properties should be applied to the node.
 - a) Dry parts (i.e. parts without a *BOUNDARY_PORE_FLUID card) will never be used (lowest priority).
 - b) If a part is initially dormant (due to staged construction inputs), it has next-lowest priority.
 - c) Parts with analysis type = drained have highest priority.
 - d) Next, higher permeability gives higher priority.
 - e) If two or more parts have equal-highest priority at a node, the part with lowest ID will win.
4. **Related Cards.** The following are cards related to this keyword:

*BOUNDARY_PWP_OPTION

*DATABASE_PWP_OUTPUT

*DATABASE_PWP_FLOW

*MAT_ADD_PERMEABILITY

*CONTROL_REFINE_ALE

Purpose: Refine ALE hexahedral solid elements locally. Each parent element is replaced by 8 child elements with a volume equal to 1/8th the parent volume. If only the 1st card is defined, the refinement occurs during the initialization. The 2nd card defines a criterion CRITRF to automatically refine the elements during the run. If the 3rd card is defined, the refinement can be removed if a criterion CRITRM is reached: the child elements can be replaced by their parents.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

| Default | 0 | 0.0 | 0 | 0.0 | 0.0 | 0.0 | 0 | 0.0 |

Automatic Refinement Remove Card. Optional card for activating automatic refinement removal whereby, when, for a cluster of 8 child elements, certain criteria are satisfied, the cluster (2x2x2 child elements) is replaced by its parent.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|--------|--------|-------|-------|-------|-------|---------|
| Variable | MAXRM | NCYCRM | CRITRM | VALRM | BEGRM | ENDRM | MMSRM | DELAYRM |
| Type | I | F | I | F | F | F | I | F |
| Default | 0 | 0.0 | 0 | 0.0 | 0.0 | 0.0 | 0 | 0.0 |

VARIABLE**DESCRIPTION**

| | |
|--------|---|
| ID | Set ID. |
| TYPE | Set type: EQ.0: ALE Part Set, EQ.1: ALE Part, EQ.2: Lagrangian Part Set coupled to ALE (see Remarks 1 and 2), EQ.3: Lagrangian Part coupled to ALE (see Remarks 1 and 2), EQ.4: Lagrangian Shell Set coupled to ALE (see Remarks 1 and 2), EQ.5: ALE Solid Set. |
| NLVL | Number of refinement levels (see Remark 3). |
| MMSID | Multi-Material Set ID (see Remark 4): LT.0: only ALE elements with all the multi-material groups listed in *SET_MULTI-MATERIAL_GROUP_LIST can be refined (or removed otherwise) GT.0: ALE elements with at least one of the multi-material groups can be refined (or removed) |
| IBOX | Box ID (See *DEFINE_BOX) defining a region in which the ALE elements are refined. |
| IELOUT | Flag to handle child data in elout (see Remarks 10 and 11). |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| NTOTRF | Total number of ALE elements to refine (see Remark 5): GT.0: Number of elements to refine EQ.0: NTOTRF = number of solid elements in IBOX (see Remark 2) LT.0: NTOTRF is the id of *CONTROL_REFINE_MPP_DISTRIBUTION that computes the number of extra elements required by processors. |
| NCYCRF | Number of cycles between each refinement. LT.0: NCYCRF is the time interval |
| CRITRF | Refinement criterion: EQ.0: static refinement (as if only the 1st card is defined), EQ.1: Pressure (if pressure > VALRF), EQ.2: Relative Volume (if $V/V_0 < VALRF$), EQ.3: Volume Fraction (if Volume fraction > VALRF), EQ.5: User defined criterion. The fortran routine alerfn_criteria5 in the file dynrfn_user.f should be used to develop the criterion. The file is part of the general package usermat. |
| VALRF | Criterion value to reach for the refinement. |
| BEGRF | Time to begin the refinement. |
| ENDRF | Time to end the refinement. |
| LAYRF | Number of element layers to refine around a element reaching the refinement criterion (see Remark 6). |
| DELAYRF | Period of time after removing the refinement of an element, during which this element will not be refined again. |
| MAXRM | Maximum number of child clusters (cluster = 2x2x2 child elements) to remove (see Remark 9): LT.0: for the whole run, GT.0: every NCYCRM cycles |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| NCYCRM | Number of cycles between each check for refinement removal: LT.0: NCYCRM is the time interval |
| CRITRM | Criterion for refinement removal: EQ.0: no refinement removal (as if only the 1st and 2nd card are defined), EQ.1: Pressure (if pressure < VALRM), EQ.2: Relative Volume (if V/Vo > VALRM) , EQ.3: Volume Fraction (if Volume fraction < VALRM), EQ.5: User defined criterion. The fortran routine <code>alermv_criteria5</code> in the file <code>dynrfn_user.f</code> should be used to develop the criterion. The file is part of the general package <code>usermat</code> . |
| VALRM | Criterion value to reach in each child element of a cluster for its removal (child elements replaced by parent element). |
| BEGRM | Time to begin the check for refinement removal: LT.0: BEGRM represents a critical percent of NTOTRF below which the check for refinement removal should begin (0.0 < BEGRM < 1.0). (See Remark 8). |
| ENDRM | Time to end the check for refinement removal. |
| MMSRM | Multi-Material Set ID for the refinement removal. (See Remark 7) LT.0: MMSRM represents the radius of a sphere centered on a newly refined element, in which the refinement can not be removed. |
| DELAYRM | Period of time after refining an element, during which this refinement will not be removed. |

Remarks:

1. If only the 1st card is defined, only TYPE = 0, 1, 5 can be defined.
2. *CONSTRAINED_LAGRANGE_IN_SOLID needs to be defined for TYPE = 2, 3, 4. If an ALE element has at least one coupling point (see NQUAD in *CONSTRAINED_LAGRANGE_IN_SOLID), this element will be selected to be re-

fined (or removed). The number of elements to refine is computed during the initialization. NTOTRF can be zero. Otherwise it can be used to add more elements.

3. If NLVL = 1, there is only one level of refinement: the ALE elements in *ELEMENT_SOLID are the only ones to be replaced by clusters of 8 child elements. If NLVL > 1, there are several levels of refinement: not only the initial ALE elements in *ELEMENT_SOLID are refined but also their child elements.
4. If only the 1st card is defined, a multi-material set id is not used. It can be left to zero. For the 2nd and 3rd cards, MMSID is the ID of *SET_MULTI-MATERIAL_GROUP_LIST in which the multi-material group ids (as defined in *ALE_MULTI-MATERIAL_GROUP) are listed to select the ALE elements to be refined (or removed). If MMSID < 0, only mixed ALE elements containing all the multi-material groups can be refined. Otherwise clusters of 8 elements without a mix of the listed multi-material groups can be removed.
5. NTOTRF defines the total number of ALE elements to be refined. So for example NTOTRF = 100 with NLVL = 1 means that only 100 ALE elements can be replaced by 800 ALE finer elements (or 100 clusters of 8 child elements). For NLVL = 2, these 800 elements can be replaced by 6400 finer elements.
6. If an element is refined, it is possible to refine the neighbor elements as well. LAYRF defines the number of neighbor layers to refine. For example, LAYRF = 2 for an element at the center of a block of 5 × 5 × 5 elements will refine these 125 elements.
7. If MMSRM = 0, all the child clusters (cluster = 2x2x2 child elements) meeting the removal criteria can be deleted. If MMSRM is defined, only ALE child clusters fully filled by the multi-material groups listed by the set MMSRM can be removed (if the refinement removal criterion is reached).
8. If BEGRM < 0, the check for refinement removal is activated when the number of 8-element clusters for the refinement is below a limit defined by |BEGRM| * NTOTRF. If |BEGRM| = 0.1, it means that the check for refinement removal starts when 90% of the stock of clusters is used for the refinement.
9. MAXRM < 0 defines a total number of child clusters to remove for the whole run. If positive, MAXRM defines an upper limit for the number of child clusters to remove every NCYCRM cycles.
10. If only the 1st card is defined, the code for IELOUT is always activated. Since the refinement occurs during the initialization, every refined element is replaced by its 8 children in the set defined for *DATABASE_ELOUT.

11. If there are more than 1 line, the code for IELOUT is activated if the flag is equal to 1. Since the refinement occurs during the run, the parent ids in the set defined for *DATABASE_ELOUT are duplicated 8^{NLVL} times. The points of integration in the elout file are incremented to differentiate the child contributions to the database.

***CONTROL_REFINE_ALE2D**

Purpose: Refine ALE quadrilateral shell elements locally. Each parent element is replaced by 4 child elements with a volume equal to 1/4th the parent volume. If only the 1st card is defined, the refinement occurs during the initialization. The 2nd card defines a criterion CRITRF to automatically refine the elements during the run. If the 3rd card is defined, the refinement can be removed if a criterion CRITRM is reached: the child elements can be replaced by their parents.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|-------|------|--------|---|---|
| Variable | ID | TYPE | NLVL | MMSID | IBOX | IELOUT | | |
| Type | I | I | I | I | I | I | | |
| Default | none | 0 | 1 | 0 | 0 | 0 | | |

Remaining cards are optional.†

Automatic refinement card. Optional card for activating automatic refinement whereby each element satisfying certain criteria is replaced by a cluster of 4 child elements (2x2 elements)

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|--------|-------|-------|-------|-------|---|
| Variable | NTOTRF | NCYCRF | CRITRF | VALRF | BEGRF | ENDRF | LAYRF | |
| Type | I | F | I | F | F | F | I | |
| Default | 0 | 0.0 | 0 | 0.0 | 0.0 | 0.0 | 0 | |

Automatic Refinement Remove Card. Optional card for activating automatic refinement removal whereby, when, for a cluster of 4 child elements, certain criteria are satisfied the clusters (2x2 child elements) is replaced by its parent.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

| Default | 0 | 0.0 | 0 | 0.0 | 0.0 | 0.0 | 0 | |

VARIABLE**DESCRIPTION**

| | |
|--------|---|
| ID | Set ID. |
| TYPE | Set type: EQ.0: ALE Part Set, EQ.1: ALE Part, EQ.2: Lagrangian Part Set coupled to ALE (see Remarks 1 and 2), EQ.3: Lagrangian Part coupled to ALE (see Remarks 1 and 2), EQ.4: Lagrangian Beam Set coupled to ALE (see Remarks 1 and 2), EQ.5: ALE Shell Set. |
| NLVL | Number of refinement levels (see Remark 3). |
| MMSID | Multi-Material Set ID (see Remark 4): LT.0: only ALE elements with all the multi-material groups listed in *SET_MULTI-MATERIAL_GROUP_LIST can be refined (or removed otherwise) GT.0: ALE elements with at least one of the multi-material groups can be refined (or removed) |
| IBOX | Box ID (See *DEFINE_BOX) defining a region in which the ALE elements are refined. |
| IELOUT | Flag to handle child data in elout (see Remarks 10 and 11). |

| VARIABLE | DESCRIPTION |
|----------|--|
| NTOTRF | Total number of ALE elements to refine (see Remark 5): GT.0: Number of elements to refine EQ.0: NTOTRF = number of shell elements in IBOX (see Remark 2) |
| NCYCRF | Number of cycles between each refinement. LT.0: NCYCRF is the time interval |
| CRITRF | Refinement criterion: EQ.0: static refinement (as if only the 1st card is defined), EQ.1: Pressure (if pressure > VALRF), EQ.2: Relative Volume (if $V/V_0 < VALRF$), EQ.3: Volume Fraction (if Volume fraction > VALRF), EQ.5: User defined criterion: The fortran routine al2rfn_criteria5 in the file dynrfn_user.f should be used to develop the criterion. The file is part of the general package usermat. |
| VALRF | Criterion value to reach for the refinement. |
| BEGRF | Time to begin the refinement. |
| ENDRF | Time to end the refinement. |
| LAYRF | Number of element layers to refine around a element reaching the refinement criterion (see Remark 6). |
| MAXRM | Maximum number of child clusters (cluster = 2x2 child elements) to remove (see Remark 9): LT.0: for the whole run, GT.0: every NCYCRM cycles |
| NCYCRM | Number of cycles between each check for refinement removal: LT.0: NCYCRM is the time interval |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| CRITRM | <p>Criterion for refinement removal:</p> <p>EQ.0: no refinement removal (as if only the 1st and 2nd card are defined),</p> <p>EQ.1: Pressure (if pressure < VALRM),</p> <p>EQ.2: Relative Volume (if $V/V_0 > VALRM$) ,</p> <p>EQ.3: Volume Fraction (if Volume fraction < VALRM),</p> <p>EQ.5: User defined criterion: The fortran routine al2rmv_criteria5 in the file dynrfn_user.f should be used to develop the criterion. The file is part of the general package usermat.</p> |
| VALRM | Criterion value to reach in each child element of a cluster for its removal (child elements of a cluster replaced by parent element). |
| BEGRM | <p>Time to begin the check for refinement removal:</p> <p>LT.0: BEGRM represents a critical percent of NTOTRF below which the check for refinement removal should begin ($0.0 < BEGRM < 1.0$). (See Remark 8).</p> |
| ENDRM | Time to end the check for refinement removal. |
| MMSRM | Multi-Material Set ID for the refinement removal. (See Remark 7) |

Remarks:

1. If only the 1st card is defined, only TYPE = 0,1,5 can be defined.
2. *CONSTRAINED_LAGRANGE_IN_SOLID needs to be defined for TYPE = 2,3,4. If an ALE element has at least one coupling point (see NQUAD in *CONSTRAINED_LAGRANGE_IN_SOLID), this element will be selected to be refined (or removed).
3. If NLVL = 1, there is only one level of refinement: the ALE elements in *ELEMENT_SHELL are the only ones to be replaced by clusters of 4 child elements. If NLVL > 1, there are several levels of refinement: not only the initial ALE elements in *ELEMENT_SHELL are refined but also their child elements. If NLVL = 2 for example, the initial ALE elements can be replaced by clusters of 16 child elements.
4. If only the 1st card is defined, a multi-material set id is not used. It can be left to zero. For the 2nd and 3rd cards, MMSID is the ID of *SET_MULTI-MATERI-

AL_GROUP_LIST in which the multi-material group ids (as defined in *ALE_MULTI-MATERIAL_GROUP) are listed to select the ALE elements to be refined (or removed). If MMSID < 0, only mixed ALE elements containing all the multi-material groups can be refined. Otherwise clusters of 4 elements without a mix of the listed multi-material groups can be removed.

5. NTOTRF defines the total number of ALE elements to be refined. So for example NTOTRF = 100 means that only 100 ALE elements will be replaced by 400 ALE finer elements (or 100 clusters of 4 child elements). For NLVL = 2, these 400 elements can be replaced by 1600 finer elements.
6. If an element is refined, it is possible to refine the neighbor elements as well. LAYRF defines the number of neighbor layers to refine. For example, LAYRF = 2 for an element at the center of a block of 5 × 5 elements will refine these 25 elements.
7. If MMSRM = 0, all the child clusters (cluster = 2×2 child elements) meeting the removal criteria can be deleted. If MMSRM is defined, only ALE child elements fully filled by the multi-material groups listed by the set MMSRM can be removed (if the refinement removal criterion is reached).
8. If BEGRM < 0, the check for refinement removal is activated when the number of 4-element clusters for the refinement is below a limit defined by |BEGRM| * NTOTRF. If |BEGRM| = 0.1, it means that the check for refinement removal starts when 90% of the stock of clusters is used for the refinement.
9. MAXRM < 0 is the exact opposite of NTOTRF > 0 and it defines a total number of child clusters to remove for the whole run. If positive, MAXRM defines an upper limit for the number of child clusters to remove every NCYCRM cycles
10. If only the 1st card is defined, the code for IELOUT is always activated. Since the refinement occurs during the initialization, every refined element is replaced by its 4 children in the set defined for *DATABASE_ELOUT.
11. If there are more than 1 line, the code for IELOUT is activated if the flag is equal to 1. Since the refinement occurs during the run, the parent ids in the set defined for *DATABASE_ELOUT are duplicated 4^{NLVL} times. The points of integration in the elout file are incremented to differentiate the child contributions to the database.

***CONTROL_REFINE_MPP_DISTRIBUTION**

Purpose: Distribute the elements for the refinement over the MPP processes. This keyword addresses the following situation:

If TYPE = 2, 3, or 4 in *CONTROL_REFINE_ALE, the refinement occurs around a structure. The number of elements for this refinement is computed for each process according the initial position of the structure in each MPP subdomain (after the MPP decomposition of the ALE mesh during phase 3 of the initialization, each process has a subdomain that is a portion of the ALE mesh). If the structure is not in a subdomain, the related process receives no extra element for the refinement. If the structure moves into this subdomain during the computation, the refinement around the structure can not occur. To avoid this problem, the structure can be considered within a box (the structure maxima and minima give the box dimensions and positions). This box moves and expands during the computation to keep the structure inside. An estimation of the maximal displacement and expansion will allow the code to evaluate which subdomains the structure will likely cross and how many extra elements a process may need to carry out the refinement.

The computation of the number of extra elements per process occurs in 2 steps:

- If a file called refine_mpp_distribution does not exist in the working directory, it will be created to list the number of elements by process. Each line in this file matches a process rank (starting from 0). After phase 3 of the MPP decomposition, the run terminates as if *CONTROL_MPP_DECOMPOSITION_SHOW was activated.
- The model can be run again and the file refine_mpp_distribution will be read to allocate the memory for the extra elements and distribute them across the processes.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|-----|-----|-----|-----|-----|---|
| Variable | ID | DX | DY | DZ | EX | EY | EZ | |
| Type | I | F | F | F | F | F | F | |
| Default | none | 0.0 | 0.0 | 0.0 | 1.0 | 1.0 | 1.0 | |

VARIABLE**DESCRIPTION**

ID

ID = -NTOTRF in *CONTROL_REFINE_ALE

| VARIABLE | DESCRIPTION |
|----------|--|
| DX | Dimensionless x -displacement of the box. (see Remark 1). |
| DY | Dimensionless y -displacement of the box. (see Remark 1). |
| DZ | Dimensionless z -displacement of the box. (see Remark 1). |
| EX | Dimensionless x -expansion of the box. (see Remark 2). |
| EY | Dimensionless y -expansion of the box. (see Remark 2). |
| EZ | Dimensionless z -expansion of the box. (see Remark 2). |

Remarks:

- Box Displacements.** DX, DY and DZ are the maximal displacements of the box center. These displacements are ratio of the box dimensions. If, for example, the largest length of the structure in the x -direction is 10 m and the maximal displacement in this direction is 2 m, DX should be equal to 0.2.
- Maximal Box Dilations.** EX, EY and EZ represent the maximal dilatations of the box in each direction. These expansions are the ratio of the box dimensions. The box expands around its center. If, for example, the maximal thickness of a structure along the z -direction is 1 cm and the structure deforms 30 times the thickness in z -direction, EZ should be equal to 30, and DZ = 15 accounts for the box center motion. The xy -plane is a plane of symmetry for this deformation; DZ can be zero.

*CONTROL

*CONTROL_REFINE_SHELL

*CONTROL_REFINE_SHELL

Purpose: Refine quadrilateral shell elements locally. Each parent element is replaced by 4 child elements, each with a volume equal to 1/4 the parent volume.

Card Summary:

Card 1. This card is required. If only this card is defined, the refinement occurs during the initialization.

| | | | | | | | |
|----|------|------|------|--------|--|--|--|
| ID | TYPE | NLVL | IBOX | IELOUT | | | |
|----|------|------|------|--------|--|--|--|

Card 2. This card is optional. If defined, this card sets a criterion, CRITRF, to automatically refine the elements during the run.

| | | | | | | | |

| Variable | MAXRM | NCYCRM | CRITRM | VALRM | BEGRM | ENDRM | | |
| Type | I | F | I | F | F | F | | |
| Default | 0 | 0.0 | 0 | 0.0 | 0.0 | 0.0 | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| MAXRM | Maximum number of child clusters to remove: LT.0: MAXRM is the total number of child clusters to be removed for the whole run, GT.0: Max number removed every NCYCRM cycles |
| NCYCRM | Number of cycles between each check for refinement removal: LT.0: NCYCRM is the time interval |
| CRITRM | Criterion for refinement removal: EQ.0: No refinement removal (as if only the 1 st and 2 nd cards are defined), |

| VARIABLE | DESCRIPTION |
|----------|---|
| | EQ.1: Pressure (if pressure < VALRM), EQ.2: undefined, EQ.3: Von Mises criterion, EQ.4: Criterion similar to ADPOPT = 4 in *CONTROL_ADAPTIVE (VALRF = ADPTOL), EQ.5: User defined criterion. The fortran routine shlrnv_criteria5 in the file dynrfn_user.f should be used to develop the criterion. The file is part of the general package usermat. |
| VALRM | Criterion value to reach in each child elements of a cluster for its removal (child elements replaced by parent element). |
| BEGRM | Time to begin the check for refinement removal. LT.0: BEGRM represents a critical percent of NTOTRF below which the check for refinement removal should begin (0.0 < BEGRM < 1.0). See Remark 4 . |
| ENDRM | Time to end the check for refinement removal. |

Remarks:

- Refinement Level.** If NLVL = 1, there is only one level of refinement; the elements in *ELEMENT_SHELL are the only ones to be replaced by clusters of 4 child elements. If NLVL > 1, there are several levels of refinement; not only the initial elements in *ELEMENT_SHELL are refined but also their child elements. If NLVL = 2 for example, the initial elements can be replaced by clusters of 16 child elements.
- Number of Parent Elements.** NTOTRF > 0 defines the total number of elements to be refined. For example, NTOTRF = 100 with NLVL = 1 means that only 100 elements can be replaced by 400 finer elements (or 100 clusters of 4 child elements). For NLVL = 2, these 400 elements can be replaced by 1600 finer elements.
- Neighboring Element Refinement.** If an element is refined, neighboring elements may be refined as well. LAYRF defines the number of neighbor layers to refine. For example, LAYRF = 2 for an element at the center of a block of 5 × 5 elements will cause these 25 elements to be refined.

4. **Refinement Removal Activation.** If $BEGRM < 0$, the check for refinement removal is activated when the number of 4-element clusters for the refinement is below a limit defined by $|BEGRM| \times NTOTRF$. If $|BEGRM| = 0.1$, the check for refinement removal starts when 90% of the stock of clusters is used for the refinement.
5. **IELOUT.** If only the 1st card is defined, the code for IELOUT is always activated. Since the refinement occurs during the initialization, every refined element is replaced by its 4 children in the set defined for *DATABASE_ELOUT.

If more than the 1st card is defined, the code for IELOUT is activated if the flag is equal to 1. Since the refinement occurs during the run, the parent IDs in the set defined for *DATABASE_ELOUT are duplicated 4^{NLVL} times. The points of integration in the elout file are incremented to differentiate the child contributions to the database.

***CONTROL_REFINE_SOLID**

Purpose: Refine hexahedral solid elements locally. Each parent element is replaced by 8 child elements with a volume equal to $1/8^{\text{th}}$ the parent volume. If only the 1st card is defined, the refinement occurs during the initialization. The 2nd card defines a criterion CRITRF to automatically refine the elements during the run. If the 3rd card is defined, the refinement can be removed if a criterion CRITRM is reached: the child elements can be replaced by their parents.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

VARIABLE**DESCRIPTION**

| | |
|--------|---|
| ID | Set ID. LT.0: parent elements can be hidden in LS-PrePost as they are replaced by their children. |
| TYPE | Set type: EQ.0: Part Set, EQ.1: Part, EQ.2: Solid Set. |
| NLVL | Number of refinement levels. See Remark 1 . |
| IBOX | Box ID (See *DEFINE_BOX) defining a region in which the elements are refined. |
| IELOUT | Flag to handle child data in elout. See Remarks 6 and 7 . |
| NTOTRF | Total number of elements to refine. See Remark 2 . GT.0: Number of elements to refine EQ.0: NTOTRF = number of solid elements in IBOX |
| NCYCRF | Number of cycles between each refinement. LT.0: NCYCRF is the time interval |

| VARIABLE | DESCRIPTION |
|----------|--|
| CRITRF | Refinement criterion: EQ.0: static refinement as if only the 1 st card is defined, EQ.1: Pressure, if pressure > VALRF, EQ.2: undefined , EQ.3: Von Mises criterion. EQ.5: User defined criterion. The fortran routine <code>sldrfn_criteria5</code> in the file <code>dynrfn_user.f</code> should be used to develop the criterion. The file is part of the general package <code>usermat</code> . |
| VALRF | Criterion value to reach for the refinement. |
| BEGRF | Time to begin the refinement. |
| ENDRF | Time to end the refinement. |
| LAYRF | Number of element layers to refine around an element reaching the refinement criterion. See Remark 3 . |
| MAXRM | Maximum number of child clusters to remove. See Remark 5 . LT.0: for the whole run, GT.0: every NCYCRM cycles |
| NCYCRM | Number of cycles between each check for refinement removal: LT.0: NCYCRM is the time interval |
| CRITRM | Criterion for removal of refinement: EQ.0: no removal of refinement as if only the 1 st and 2 nd card are defined, EQ.1: Pressure if pressure < VALRM, EQ.2: undefined, EQ.3: Von Mises criterion. EQ.5: User defined criterion. The FORTRAN routine <code>sldrmv_criteria5</code> in the file <code>dynrfn_user.f</code> should be used to develop the criterion. The file is part of the general package <code>usermat</code> . |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| VALRM | Criterion value to reach in each child element of a cluster for its removal (replace child elements with parent element). |
| BEGRM | Time to begin check for refinement removal: LT.0: BEGRM represents a critical percent of NTOTRF below which the check for refinement removal should begin (0.0 < BEGRM < 1.0). See Remark 4 . |
| ENDRM | Time to end the check for refinement removal. |

Remarks:

- Number of Refinement Levels.** If $NLVL = 1$, there is only one level of refinement: the elements in *ELEMENT_SOLID are the only ones to be replaced by clusters of 8 child elements. If $NLVL > 1$, there are several levels of refinement: not only the initial elements in *ELEMENT_SOLID are refined but also their child elements. If $NLVL = 2$ for example, the initial elements can be replaced by clusters of 64 child elements.
- Maximum Number of Elements to Refine.** NTOTRF defines the total number of elements to be refined. For example, $NTOTRF = 100$ with $NLVL = 1$ means that only 100 elements can be replaced by 800 finer elements (or 100 clusters of 8 child elements). For $NLVL = 2$, these 800 elements can be replaced by 6400 finer elements.
- Number of Layers to Refine.** If an element is refined, it is possible to refine the neighbor elements as well. LAYRF defines the number of neighbor layers to refine. For example, $LAYRF = 2$ for an element at the center of a block of $5 \times 5 \times 5$ elements will refine these 125 elements.
- Onset of Refinement Removal.** If $BEGRM < 0$, the check for refinement removal is activated when the number of 8-element clusters for the refinement is below a limit defined by $|BEGRM| \times NTOTRF$. If $|BEGRM| = 0.1$, it means that the check for refinement removal starts when 90% of the stock of clusters are used for the refinement.
- Maximum Refinement Removal.** $MAXRM < 0$ defines a total number of child clusters to remove for the whole run. If positive, MAXRM defines an upper limit for the number of child clusters to remove every NCYCRM cycles.

6. **The elout Database and Initial Refinement.** If only the 1st card is defined, the code for IELOUT is always activated. Since the refinement occurs during the initialization, every refined element is replaced by its 8 children in the set defined for *DATABASE_ELOUT.

7. **The elout Database and Refinement at Run Time.** If there is more than 1 line, the code for IELOUT is activated if the flag is equal to 1. Since the refinement occurs during the run, the parent IDs in the set defined for *DATABASE_ELOUT are duplicated 8^{NLVL} times. The points of integration in the elout file are incremented to differentiate the child contributions to the database.

***CONTROL_REMESHING_{OPTION}**

Available options include:

<BLANK>

EFG

Purpose: Provide control over the remeshing of solids which are meshed with the solid tetrahedron element type 13 and mesh-free solid types 41, 42. The element size for three-dimensional adaptivity can be set on the surface mesh of the solid part, and adaptivity can be activated based on the criteria of volume loss, mass increase, or minimum time step size. In addition, so-called interactive adaptivity triggers can be invoked using the EFG option.

There are two types of 3-D solid adaptivity affected by *CONTROL_REMESHING:

1. General tetrahedral adaptivity for which the EFG option of *CONTROL_REMESHING may be invoked. See ADPOPT = 2 in *PART.
2. Axisymmetric adaptivity, sometimes called orbital adaptivity, in which remeshing is done with hexahedral and pentahedral elements. See ADPOPT = 3 in *PART. The EFG option of *CONTROL_REMESHING does not apply for this type of adaptivity.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

| Variable | IAT1 | IAT2 | IAT3 | | | | | |
| Type | F | F | F | | | | | |
| Default | 10 ²⁰ | 10 ²⁰ | 10 ²⁰ | | | | | |

VARIABLE**DESCRIPTION**

| | |
|---------|---|
| RMIN | Minimum edge length for the surface mesh surrounding the parts which should be remeshed. See Remark 1 . |
| RMAX | Maximum edge length for the surface mesh surrounding the parts which should be remeshed. See Remark 1 . |
| VF_LOSS | Volume fraction loss required in a type 13 tetrahedral elements to trigger a remesh. For the type 13 solid elements, the pressures are computed at the nodal points; therefore, it is possible for volume to be conserved but for individual tetrahedrons to experience a significant volume loss or gain. The volume loss can lead to numerical problems. Recommended values for VF_LOSS in the range of 0.10 to 0.30 may be reasonable. |
| MFRAC | Mass ratio gain during mass scaling required for triggering a remesh. For a one percent increase in mass, set MFAC = 0.010. This variable applies to both to general three dimensional tetrahedral remeshing and to three dimensional axisymmetric remeshing. |
| DT_MIN | Time step size required for triggering a remesh. This option applies only to general three dimensional tetrahedral remeshing and is checked before mass scaling is applied and the time step size reset. |
| ICURV | Define number of elements along the radius in the adaptivity. See Remark 3 . |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| CID | <p>Coordinate system ID for three dimensional axisymmetric remeshing. The z-axis in the defined coordinate system is the orbital axis, and has to be parallel to the global z-axis in the current axisymmetric remesher.</p> <p>EQ.0: use global coordinate, and the global z-axis is the orbital axis (default)</p> |
| SEGANG | <p>For Axisymmetric 3-D remeshing: Angular element size (degrees).</p> <p>For General (tet) 3-D remeshing: Critical angle specified in radians to preserve feature lines.</p> |
| IVT | <p>Internal variable transfer in adaptive EFG.</p> <p>EQ.1: Moving Least Square approximation with Kronecker-delta property (recommended in general case).</p> <p>EQ.-1: Moving Least Square approximation without Kronecker-delta property.</p> <p>EQ.2: Partition of unity approximation with Kronecker-delta property.</p> <p>EQ.-2: Partition of unity approximation without Kronecker-delta property.</p> <p>EQ.-3: Finite element approximation.</p> |
| IAT | <p>Flag for interactive adaptivity (see Remark 2):</p> <p>EQ.0: No interactive adaptivity.</p> <p>EQ.1: Interactive adaptivity combined with predefined adaptivity.</p> <p>EQ.2: Purely interactive adaptivity. The time interval between two successive adaptive steps is bounded by ADPFREQ.</p> <p>EQ.3: Purely interactive adaptivity.</p> |
| IAAT | <p>Interactive adaptivity adjustable tolerance.</p> <p>EQ.0: The tolerance to trigger interactive adaptivity is not adjusted.</p> <p>EQ.1: The tolerance is adjusted in run-time to avoid over-activation.</p> |

| VARIABLE | DESCRIPTION |
|----------|--|
| IER | Interactive adaptive remeshing with element erosion for metal cutting. EQ.1: The failed elements are eroded and the cutting surface is reconstructed before adaptive remeshing. The current implementation only supports SMP and IAT = 1, 2, 3. |
| MM | Interactive adaptive remeshing with monotonic resizing. EQ.1: The adaptive remeshing cannot coarsen a mesh. The current implementation only supports IAT = 1, 2, 3 and IER = 0. |
| IAT1 | Shear strain tolerance for interactive adaptivity. If the shear strain in any formulation 42 EFG tetrahedral element exceeds IAT1, remeshing is triggered. (0.1 ~ 0.5 is recommended). |
| IAT2 | L_{\max}/L_{\min} tolerance where L_{\max} and L_{\min} are the maximum and minimum edge lengths of any given formulation 42 EFG tetrahedral element. If this ratio in any element exceeds IAT2, remeshing is triggered. (RMAX/RMIN is recommended.) |
| IAT3 | Volume change tolerance. If the normalized change in volume of any formulation 42 tetrahedral element, defined as $ v_1 - v_0 / v_0 $ where v_1 is the current element volume and v_0 is the element volume immediately after the most recent remeshing, exceeds IAT3, remeshing is triggered. (0.5 is recommended.) |

Remarks:

- Edge Length.** The value of RMIN and RMAX should be of the same order. The value of RMAX can be set to 2-5 times greater than RMIN.
- Interactive Adaptivity.** When interactive adaptivity is invoked (IAT > 0), even if none of the tolerances IAT1, IAT2, and IAT3 for the three respective indicators (shear strain, edge length ratio, normalized volume change) are exceeded, remeshing will still be triggered if any of the three indicators over a single explicit time step changes by more than 50%, that is, if

$$\frac{|[\text{value}]_n - [\text{value}]_{n-1}|}{|[\text{value}]_{n-1}|} > 0.5$$

where $[\text{value}]_n$ denotes value of indicator in n^{th} (current) time step and $[\text{value}]_{n-1}$ denotes value of indicator in previous time step. This condition is checked only if $[\text{value}]_{n-1}$ is nonzero.

3. **ICURV.** ICURV represents a number of elements and applies only when ADPENE > 0 in *CONTROL_ADAPTIVE. The “desired element size” at each point on slave contact surface is computed based on the tooling radius of curvature (see the description of ADPENE in *CONTROL_ADAPTIVE), so that ICURV elements would be used to resolve a hypothetical 90 degree arc at the tooling radius of curvature. The value of ICURV is (internally) limited to be ≥ 2 and ≤ 12 . The final adapted element size is adjusted as necessary to fall within the size range set forth by RMIN and RMAX.

*CONTROL_REQUIRE_REVISION

Purpose: To prevent the model from being run in old versions of LS-DYNA. This might be desirable due to known improvements in the program, required capability, etc.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---------|----------|---|---|---|---|---|---|
| Variable | RELEASE | REVISION | | | | | | |
| Type | C | I | | | | | | |
| Default | Rem 2 | none | | | | | | |

VARIABLE

DESCRIPTION

| | |
|----------|---|
| RELEASE | The release of code required. This should be a string such as "R6.1.0" or "R7.0" |
| REVISION | The minimum revision required. This corresponds to the "SVN Version" field in the d3hsp file. |

Remarks:

- Number of Lines.** Any number of lines can appear, indicating for example that a particular feature was introduced in different release branches at different times.
- RELEASE.** If the RELEASE field is left empty, then any executable whose development split from the main SVN trunk after the given REVISION will be allowed.

Example:

```
*CONTROL_REQUIRE_REVISION
R6.1      79315
R7.0      78310
          78304
```

The above example would prevent execution by any R6.1 executable before r79315, any R7.0 before r78310, and all other executables whose development split from the main trunk before r78304. Note that no versions of R6.0, R6.0.0, or R6.1.0 are allowed: R6.1

does NOT imply R6.1.0, no matter what the revision of R6.1.0 – R6.1.0 would have to be explicitly listed. Similarly, R7.0.0 would not be allowed because it is not listed, and it split from the trunk in r76398. Any future R8.X executable would be allowed, since it will have split from the trunk after r78304.

***CONTROL_RIGID**

Purpose: Special control options related to rigid bodies and to linearized flexible bodies, see *PART_MODES.

VARIABLE**DESCRIPTION**

LMF

Switch the explicit rigid body joint treatment to an implicit formulation which uses Lagrange multipliers to impose prescribed kinematic boundary conditions and joint constraints. There is a slight cost overhead due to the assembly of sparse matrix equations which are solved using standard procedures for nonlinear problems in rigid multi-body dynamics. Lagrange multiplier flag:

EQ.0: explicit penalty formulation

EQ.1: implicit formulation with Lagrange multipliers

| VARIABLE | DESCRIPTION |
|-----------------|---|
| JNTF | Generalized joint stiffness formulation; see Remark 1 below: EQ.0: incremental update EQ.1: total formulation (exact) EQ.2: total formulation intended for implicit analysis |
| ORTHMD | Orthogonalize modes with respect to each other: EQ.0: true EQ.1: false, the modes are already orthogonalized |
| PARTM | Use global mass matrix to determine part mass distribution. This mass matrix may contain mass from other parts that share nodes. See Remark 2 below. EQ.0: true EQ.1: false |
| SPARSE | Use sparse matrix multiply subroutines for the modal stiffness and damping matrices. See Remark 3 . EQ.0: false, do full matrix multiplies (frequently faster). EQ.1: true |
| METALF | Metal forming option, which should not be used for crash and other applications involving rigid bodies. Use fast update of rigid body nodes. If this option is active, the rotational motion of all rigid bodies should be suppressed. EQ.0: full treatment is used EQ.1: fast update for metal forming applications |
| PLOTEL | Automatic generation of *ELEMENT_PLOTEL for *CONSTRAINED_NODAL_RIGID_BODY. EQ.0: no generation EQ.1: one part is generated for all nodal rigid bodies with the PID set to 1000000. EQ.2: one part is generated for each nodal rigid body in the problem with a part ID of 1000000 + PID, where PID is the nodal rigid body ID. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| RBSMS | <p>Flag to apply consistent treatment of rigid bodies in selective and conventional mass scaling, Remark 4.</p> <p>EQ.0: Off</p> <p>EQ.1: On</p> |
| NORBIC | <p>Circumvent rigid body inertia check, see Remark 5.</p> <p>EQ.0: Off</p> <p>EQ.1: On</p> |
| GJADSTF | <p>Rotational stiffness is added to all joints in the model as a mean to model a small resistance, such as joint friction, or to avoid zero energy modes in implicit. This is equivalent to defining a <code>*CONSTRAINED_ JOINT_STIFFNESS_GENERALIZED</code> to the free rotational degrees of freedom of all joints, using a slope in <code>LCIDPH</code>, <code>LCIDT</code>, <code>LCIDPS</code> that equal to <code>GJADSTF</code>. For models with many joints this field is advantageous since it only has to be defined once for all joints, whereas the equivalent keyword must be defined for each joint.</p> |
| GJADVSC | <p>Rotational damping is added to all joints in the model as a mean to model a small resistance, such as joint friction, or to avoid zero energy modes in implicit. This is equivalent to defining a <code>*CONSTRAINED_ JOINT_STIFFNESS_GENERALIZED</code> to the free rotational degrees of freedom of all joints, using a slope in <code>DLCIDPH</code>, <code>DLCIDT</code>, <code>DLCIDPS</code> that equal to <code>GJADVSC</code>. Like <code>GJADSTF</code>, for models many joints this field is advantageous since it only has to be defined once for all joints, whereas the equivalent keyword must be defined for each joint.</p> |
| TJADSTF | <p>Translational stiffness is added to all joints in the model as a mean to model a small resistance, such as joint friction, or to avoid zero energy modes in implicit. This is equivalent to defining <code>a</code> <code>*CONSTRAINED_ JOINT_STIFFNESS_TRANSLATIONAL</code> to the free translational degrees of freedom of all joints, using a slope in <code>LCIDX</code>, <code>LCIDY</code>, <code>LCIDZ</code> that equal to <code>TJADSTF</code>. Like <code>GJADSTF</code>, for models many joints this field is advantageous since it only has to be defined once for all joints, whereas the equivalent keyword must be defined for each joint.</p> |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| TJADVSC | Translational damping is added to all joints in the model as a mean to model a small resistance, such as joint friction, or to avoid zero energy modes in implicit. This is equivalent to defining a *CONSTRAINED_JOINT_STIFFNESS_TRANSLATIONAL to the free translational degrees of freedom of all joints, using a slope in DLCIDX , DLCIDY , DLCIDZ that equal to TJADVSC . Like GJADSTF , for models many joints this field is advantageous since it only has to be defined once for all joints, whereas the equivalent keyword must be defined for each joint. |

Remarks:

1. **JNTF.** The default behavior is for the relative angles between the two coordinate systems to be done incrementally. This is an approximation, in contrast to the total formulation where the angular offsets are computed exactly. The disadvantage of the latter approach is that a singularity exists when an offset angle equals 180 degrees. In most applications, the stop angles exclude this possibility and **JNTF=1** should not cause a problem. **JNTF=2** is implemented with smooth response and especially intended for implicit analysis.
2. **PARTM.** If the determination of the normal modes included the mass from both connected bodies and discrete masses, or if there are no connected bodies, then the default is preferred. When the mass of a given part ID is computed, the resulting mass vector includes the mass of all rigid bodies that are merged to the given part ID, but does not include discrete masses. See the keyword: ***CONSTRAINED_RIGID_BODIES**. A lumped mass matrix is always assumed.
3. **SPARSE.** Sparse matrix multipliers save a substantial number of operations if the matrix is truly sparse. However, the overhead will slow the multipliers for densely populated matrices.
4. **RBSMS.** In selective mass scaling, rigid bodies connected to deformable elements can result in significant addition of inertia due to missing terms in the SMS mass matrix. This problem has been observed in automotive applications where spotwelds are modeled using constrained nodal rigid bodies. By applying consistent rigid body treatment significant improvement in accuracy and robustness are observed at the expense of increased CPU intensity. This flag also applies to conventional mass scaling as it has been observed that inconsistencies for various reasons may result in unstable solution schemes even for this case.

5. **NORBIC.** During initialization, the determinant of the rigid body inertia tensor is checked. If it falls below a tolerance value of 10^{-30} , LS-DYNA issues an error message and the calculation stops. In some rare cases (for example with an unfavorable system of units), such tiny values would still be valid. In this case, NORBIC should be set to 1 to circumvent the implied inertia check.

*CONTROL

*CONTROL_SHELL

*CONTROL_SHELL

Purpose: Provide controls for computing shell response.

VARIABLE**DESCRIPTION****WRPANG**

Shell element warpage angle in degrees. If a warpage greater than this angle is found, a warning message is printed. Default is 20 degrees.

ESORT

Sorting of triangular shell elements to automatically switch degenerate quadrilateral shell formulations to more suitable triangular shell formulations.

EQ.0: Do not sort (default).

EQ.1: Sort (switch to C0 triangular shell formulation 4, or if a quadratic shell, switch to shell formulation 24, or if a shell formulation with thickness stretch, switch to shell formulation 27).

EQ.2: Sort (switch to DKT triangular shell formulation 17, or if a quadratic shell, switch to shell formulation 24). The DKT formulation will be unstable if used to model an uncommonly thick, triangular shell.

IRNXX

Shell normal update option. This option applies to the Hughes-Liu formulations (ELFORMs 1, 6, 7, 11), the BWC formulation (ELFORM 10), and if warping stiffness is turned on, the Belytschko-Tsay formulations (ELFORMs 2/25 with BWC = 1, and ELFORMs 16/-16/26 with the hourglass formulation set to 8).

EQ.-2: unique nodal fibers which are incrementally updated based on the nodal rotation at the location of the fiber,

EQ.-1: recomputed fiber directions each cycle,

EQ.0: default set to -1,

EQ.1: compute on restarts,

EQ.n: compute every n cycles (Hughes-Liu shells only).

| VARIABLE | DESCRIPTION |
|-----------------|---|
| ISTUPD | <p>Shell thickness change option for deformable shells. The parameter, PSTUPD, on the second optional card allows this option to be applied by part ID. For crash analysis, neglecting the elastic component of the strains, ISTUPD = 4, may improve energy conservation and stability.</p> <p>EQ.0: no thickness change.</p> <p>EQ.1: membrane straining causes thickness change in 3 and 4 node shell elements. This option is very important in sheet metal forming or whenever membrane stretching is important.</p> <p>EQ.2: membrane straining causes thickness change in 8 node thick shell elements, types 1 and 2. This option is not recommended for implicit or explicit solutions which use the fully integrated type 2 elements. Types 3 and 5 thick shells are continuum based and thickness changes are always considered.</p> <p>EQ.3: options 1 and 2 apply.</p> <p>EQ.4: option 1 applies, but the elastic strains are neglected for the thickness update. This option only applies to shells (not thick shells) and the most common elastic-plastic materials for which the elastic response is isotropic. See SIDT4TU for selective application of this option.</p> |
| THEORY | <p>Default shell formulation. For a complete list of shell formulations, refer to *SECTION_SHELL. For remarks on overriding this default and how THEORY may affect contact behavior, see Remark 2.</p> <p>EQ.1: Hughes-Liu</p> <p>EQ.2: Belytschko-Tsay (default)</p> <p>EQ.3: BCIZ triangular shell (not recommended)</p> <p>EQ.4: C0 triangular shell</p> <p>EQ.5: Belytschko-Tsay membrane</p> <p>EQ.6: S/R Hughes Liu</p> <p>EQ.7: S/R co-rotational Hughes Liu</p> <p>EQ.8: Belytschko-Leviathan shell</p> <p>EQ.9: fully integrated Belytschko-Tsay membrane</p> |

| VARIABLE | DESCRIPTION |
|----------|---|
| | EQ.10: Belytschko-Wong-Chiang |
| | EQ.11: Fast (co-rotational) Hughes-Liu |
| | EQ.12: Plane stress (x - y plane) |
| | EQ.13: Plane strain (x - y plane) |
| | EQ.14: Axisymmetric solid (y -axis of symmetry) – area weighted. See Remark 5 |
| | EQ.15: Axisymmetric solid (y -axis of symmetry) – volume weighted. See Remark 5 |
| | EQ.16: Fully integrated shell element (very fast) |
| | EQ.17: Discrete Kirchhoff triangular shell (DKT) |
| | EQ.18: Discrete Kirchhoff linear shell either quadrilateral or Triangular with 6DOF per node |
| | EQ.20: C0 linear shell element with 6 DOF per node |
| | EQ.21: C0 linear shell element with 5 DOF per node with the Pian-Sumihara membrane hybrid quadrilateral membrane |
| | EQ.25: Belytschko-Tsay shell with thickness stretch |
| | EQ.26: Fully integrated shell with thickness stretch |
| | EQ.27: C0 triangular shell with thickness stretch |
| BWC | Warping stiffness for Belytschko-Tsay shells: EQ.1: Belytschko-Wong-Chiang warping stiffness added. EQ.2: Belytschko-Tsay (default). |
| MITER | Plane stress plasticity option (applies to materials 3, 18, 19, and 24): EQ.1: iterative plasticity with 3 secant iterations (default), EQ.2: full iterative plasticity, EQ.3: radial return noniterative plasticity. May lead to false results and has to be used with great care. |
| PROJ | Projection method for the warping stiffness in the Belytschko-Tsay shell (the BWC option above) and the Belytschko-Wong-Chiang elements (see Remark 1 below). This parameter applies to explicit calculations since the full projection method is always used if the solution is implicit and this input parameter is |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | ignored. EQ.0: drill projection, EQ.1: full projection. |
| ROTASCL | Define a scale factor for the rotary shell mass. This option is not for general use. The rotary inertia for shells is automatically scaled to permit a larger time step size. A scale factor other than the default, i.e., unity, is not recommended. |
| INTGRD | Default through thickness numerical integration rule for shells and thick shells. If more than 10 integration points are requested, a trapezoidal rule is used unless a user defined rule is specified. EQ.0: Gauss integration: If 1-10 integration points are specified, the default rule is Gauss integration. EQ.1: Lobatto integration: If 3-10 integration points are specified, the default rule is Lobatto. For 2 point integration, the Lobatto rule is very inaccurate, so Gauss integration is used instead. Lobatto integration has an advantage in that the inner and outer integration points are on the shell surfaces. |
| LAMSHT | Laminated shell theory flag. Except for those using the Green-Lagrange strain tensor, laminated shell theory is available for all thin shell and thick shell materials. It is activated when LAMSHT = 3, 4, or 5 and by using *PART_COMPOSITE or *INTEGRATION_SHELL to define the integration rule. See Remark 6 . EQ.0: do not update shear corrections, EQ.1: activate laminated shell theory, EQ.3: activate laminated thin shells, EQ.4: activate laminated shell theory for thick shells, EQ.5: activate laminated shell theory for thin and thick shells. |
| CSTYP6 | Coordinate system for the type 6 shell element. The default system computes a unique local system at each in plane point. The uniform local system computes just one system used throughout the shell element. This involves fewer calculations and is therefore more efficient. The change of systems has a slight effect on results; therefore, the older, less efficient method is the |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | <p>default.</p> <p>EQ.1: variable local coordinate system (default),</p> <p>EQ.2: uniform local system.</p> |
| THSHEL | <p>Thermal shell option (applies only to thermal and coupled structural thermal analyses). See parameter THERM on DATABASE_EXTENT_BINARY keyword.</p> <p>EQ.0: No temperature gradient is considered through the shell thickness (default).</p> <p>EQ.1: A temperature gradient is calculated through the shell thickness.</p> |
| PSTUPD | <p> PSTUPD is the optional shell part set ID specifying which part ID's have or do not have their thickness updated according to ISTUPD. The shell thickness update as specified by ISTUPD by default applies to all shell elements in the mesh.</p> <p>LT.0: these shell parts are excluded from the shell thickness update</p> <p>EQ.0: all deformable shells have their thickness updated</p> <p>GT.0: these shell parts are included in the shell thickness update</p> |
| SIDT4TU | <p>Shell part set ID for parts which use the type 4 thickness update where elastic strains are ignored. The shell parts in part set SIDT4TU must also be included in the part set defined by PSTUPD. SIDT4TU has no effect unless ISTUPD is set to 1 or 3.</p> |
| CNTCO | <p>Flag affecting location of contact surfaces for shells when NLOC is nonzero in *SECTION_SHELL or in *PART_COMPOSITE, or when OFFSET is specified using *ELEMENT_SHELL_OFFSET. CNTCO is not supported for the slave side of NODES_TO_SURFACE type contacts, neither has it any effect for Mortar contacts. For Mortar contacts NLOC or OFFSET completely determines the location of the contact surfaces, as if CNTCO = 1 would be set.</p> <p>EQ.0: NLOC and OFFSET have no effect on location of shell contact surfaces.</p> <p>EQ.1: Contact reference plane (see comments below) coincides with shell reference surface.</p> <p>EQ.2: Contact reference plane (see comments below) is affected</p> |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | <p>by contact thickness. This is typically not physical.</p> <p>For automatic contact types, the shell contact surfaces are always, regardless of CNTCO, offset from a contact reference plane by half a contact thickness. Contact thickness is taken as the shell thickness by default but can be overridden, for example, with input on Card 3 of *CONTACT.</p> <p>The parameter CNTCO affects how the location of the contact reference plane is determined. When CNTCO = 0, the contact reference plane coincides with the plane of the shell nodes. Whereas when CNTCO = 1, the contact reference plane coincides with the shell reference surface as determined by NLOC or by OFFSET. For CNTCO = 2, the contact reference plane is offset from the plane of the nodes by</p> $-\frac{NLOC}{2} \times \text{contact thickness}$ <p>or by</p> $OFFSET \times \left(\frac{\text{contact thickness}}{\text{shell thickness}} \right)$ <p>whichever applies.</p> |
| ITSFLG | <p>Flag to activate/deactivate initial transverse shear stresses (local shell stress components σ_{yz} and σ_{zx}) from *INITIAL_STRESS_SHELL:</p> <p>EQ.0: keep transverse shear stresses</p> <p>EQ.1: set transverse shear stresses to zero</p> |
| IRQUAD | <p>In plane integration rule for the 8-node quadratic shell element (shell formulation 23):</p> <p>EQ.2: 2 × 2 Gauss quadrature (default),</p> <p>EQ.3: 3 × 3 Gauss quadrature.</p> |
| W-MODE | <p>W-Mode amplitude for element deletion, specified in degrees. See Figure 12-88 and Remark 4 for the definition of the angle.</p> |
| STRETCH | <p>Stretch ratio of element diagonals for element deletion. This option is activated if and only if either NFAIL1 or NFAIL4 are nonzero and STRETCH > 0.0.</p> |
| ICRQ | <p>Continuous treatment across element edges for some specified result quantities. See Remark 7.</p> |

| VARIABLE | DESCRIPTION |
|----------|--|
| NFAIL1 | <p>EQ.0: not active</p> <p>EQ.1: thickness and plastic strain</p> <p>EQ.2: thickness</p> <p>Flag to check for highly distorted under-integrated shell elements, print a message, and delete the element or terminate. Generally, this flag is not needed for one point elements that do not use the warping stiffness. A distorted element is one where a negative Jacobian exist within the domain of the shell, not just at integration points. The checks are made away from the CPU requirements for one point elements. If nonzero, NFAIL1 can be changed in a restart.</p> <p>EQ.1: print message and delete element.</p> <p>EQ.2: print message, write d3dump file, and terminate</p> <p>GT.2: print message and delete element. When NFAIL1 elements are deleted then write d3dump file and terminate. These NFAIL1 failed elements also include all shell elements that failed for other reasons than distortion. Before the d3dump file is written, NFAIL1 is doubled, so the run can immediately be continued if desired.</p> |
| NFAIL4 | <p>Flag to check for highly distorted fully-integrated shell elements, print a message and delete the element or terminate. Generally, this flag is recommended. A distorted element is one where a negative Jacobian exist within the domain of the shell, not just at integration points. The checks are made away from the integration points to enable the bad elements to be deleted before an instability leading to an error termination occurs. If nonzero, NFAIL4 can be changed in a restart.</p> <p>EQ.1: print message and delete element.</p> <p>EQ.2: print message, write d3dump file, and terminate</p> <p>GT.2: print message and delete element. When NFAIL4 elements are deleted then write d3dump file and terminate. These NFAIL4 failed elements also include all shell elements that failed for other reasons than distortion. Before the d3dump file is written, NFAIL4 is doubled, so the run can immediately be continued if desired.</p> |
| PSNFAIL | Optional shell part set ID specifying which part ID's are checked |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | by the NFAIL1, NFAIL4, and W-MODE options. If zero, all shell part ID's are included. |
| KEEPCS | Flag to keep the contact segments of failed shell elements in the calculation. The contact segments of the failed shells remain active until a node shared by the segments has no active shells attached. Only then are the segments deleted. EQ.0: Inactive EQ.1: Active |
| DELFR | Flag to delete shell elements whose neighboring shell elements have failed; consequently, the shell is detached from the structure and moving freely in space. This condition is checked if NFAIL1 or NFAIL4 are nonzero. EQ.0: Inactive EQ.1: Isolated elements are deleted. EQ.2: Elements that are isolated and triangular elements that are connected by only one node are deleted. EQ.3: Elements that are either isolated or connected by only one node are deleted. |
| DRCPSID | Part set ID for drilling rotation constraint method (see Remark 3 below). |
| DRCPRM | Drilling rotation constraint parameter (default = 1.0). |
| INTPERR | Flag for behavior in case of unwanted interpolation/extrapolation of initial stresses from *INITIAL_STRESS_SHELL. EQ.0: Only warning is written, calculation continues (default). EQ.1: Error exit, calculation stops. |

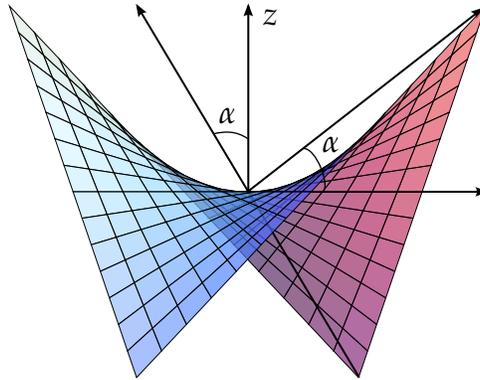

Figure 12-88. Illustration of an element in a *W-Mode*. One pair of opposite corners go up, and the other pair goes down. The angle, α , is formed by the plane of the flat element and by the vector connecting the center to the corner. See [Remark 4](#).

Remarks:

1. **Drill versus Full Projections for Warping Stiffness.** The drill projection is used in the addition of warping stiffness to the Belytschko-Tsay and the Belytschko-Wong-Chiang shell elements. This projection generally works well and is very efficient, but to quote Belytschko and Leviathan:

"The shortcoming of the drill projection is that even elements that are invariant to rigid body rotation will strain under rigid body rotation if the drill projection is applied. On one hand, the excessive flexibility rendered by the 1-point quadrature shell element is corrected by the drill projection, but on the other hand the element becomes too stiff due to loss of the rigid body rotation invariance under the same drill projection".

They later went on to add in the conclusions:

"The projection of only the drill rotations is very efficient and hardly increases the computation time, so it is recommended for most cases. However, it should be noted that the drill projection can result in a loss of invariance to rigid body motion when the elements are highly warped. For moderately warped configurations the drill projection appears quite accurate".

In crashworthiness and impact analysis, elements that have little or no warpage in the reference configuration can become highly warped in the deformed configuration and may affect rigid body rotations if the drill projection is used, i.e., **DO NOT USE THE DRILL PROJECTION.** Of course it is difficult to define what is meant by "moderately warped". The full projection circumvents these problems but at a significant cost. The cost increase of the drill projection versus no projection as reported by Belytschko and Leviathan is 12 percent and by timings in LS-DYNA, 7 percent, but for the full projection they report a 110 percent increase and in LS-DYNA an increase closer to 50 percent is observed.

In Version 940 of LS-DYNA the drill projection was used exclusively, but in one problem the lack of invariance was observed; consequently, the drill projection was replaced in the Belytschko-Leviathan shell with the full projection and the full projection is now optional for the warping stiffness in the Belytschko-Tsay and Belytschko-Wong-Chiang elements. Starting with version 950 the Belytschko-Leviathan shell, which now uses the full projection, is somewhat slower than in previous versions. In general, in light of these problems, the drill projection cannot be recommended. For implicit calculations, the full projection method is used in the development of the stiffness matrix.

2. **THEORY, ELFORM, and Contact with Tapered Shells.** All shell parts need not share the same element formulation. A nonzero value of ELFORM, given

either in *SECTION_SHELL or *PART_COMPOSITE, overrides the element formulation specified by THEORY in *CONTROL_SHELL.

When using MPP, THEORY = 1 in *CONTROL_SHELL has special meaning when dealing with non-uniform-thickness shells, that is, it serves to set the nodal contact thickness equal to the average of the nodal thicknesses from the shells sharing that node. Thus when a contact surface is comprised of non-uniform-thickness shells, THEORY = 1 is recommended and the user still has the option of setting the actual shell theory using ELFORM in *SECTION_SHELL.

- 3. **Drilling Rotation Constraint Method.** The drilling rotation constraint method which is used by default in implicit calculations (see parameter DRCM=4 on *CONTROL_IMPLICIT_SOLVER) can be used in explicit calculations as well by defining an appropriate part set DRCPSID. This might be helpful in situations where single constraints (e.g. spotwelds) are connected to flat shell element topologies. The additional drill force can be scaled with DRCPRM (default value is 1.0), where a moderate value should be chosen to avoid excessive stiffening of the structure. A speed penalty of max. 15 % may be observed with this option.
- 4. **W-Mode Failure Criterion.** The w-mode failure criteria depends on the magnitude of the w-mode, w , compared to the approximate side-length ℓ . The magnitude, w , is defined as

$$w = \frac{1}{4} [(x_1 - x_2) + (x_3 - x_4)] \cdot \mathbf{n}$$

where x_i is the position vector for node i , and \mathbf{n} is the element normal vector evaluated at the centroid. The element normal is the unit vector obtained from the cross product of the diagonal vectors \mathbf{a} and \mathbf{b} as,

$$\begin{aligned} \mathbf{a} &= \mathbf{x}_3 - \mathbf{x}_1 \\ \mathbf{b} &= \mathbf{x}_4 - \mathbf{x}_2 \\ \mathbf{n} &= \frac{\mathbf{a} \times \mathbf{b}}{\|\mathbf{a} \times \mathbf{b}\|} \end{aligned}$$

The failure criteria depends on the ratio of w to ℓ , where ℓ is defined as,

$$\ell = \frac{1}{2} \left[\underbrace{\sqrt{2} \sqrt{\frac{1}{2} \|\mathbf{a} \times \mathbf{b}\|}}_{\sim \text{diagonal length}} \right]$$

such that the element is deleted when

$$\frac{|w|}{\ell} \geq \tan(\text{WMODE}).$$

The angle α in the figure may be identified as,

$$\alpha = \arctan \left(\frac{|w|}{\ell} \right).$$

5. **2D Axisymmetric Solid Elements.** The 2D axisymmetric solid elements come in two types: area weighted (type 14) and volume weighted (type 15).
 - a) High explosive applications work best with the area weighted approach and structural applications work best with the volume weighted approach. The volume weighted approach can lead to problems along the axis of symmetry under very large deformations. Often the symmetry condition is not obeyed, and the elements will kink along the axis.
 - b) The volume weighted approach must be used if 2D shell elements are used in the mesh. Type 14 and 15 elements cannot be mixed in the same calculation.
6. **Lamination Theory.** Lamination theory should be activated when the assumption that shear strain through the shell is uniform and constant becomes violated. Unless this correction is applied, the stiffness of the shell can be grossly incorrect if there are drastic differences in the elastic constants from ply to ply, especially for sandwich type shells. Generally, without this correction the results are too stiff. For the discrete Kirchhoff shell elements, which do not consider transverse shear, this option is ignored. For thin shells of material types, *MAT_COMPOSITE_DAMAGE, *MAT_ENHANCED_COMPOSITE_DAMAGE, and *MAT_GENERAL_VISCOELASTIC, laminated shell theory may also be done by stiffness correction by setting LAMSHT=1.
7. **Continuous Result Quantities.** A nodal averaging technique is used to achieve continuity for some quantities across element edges. Applying this approach to the thickness field and plastic strains (ICRQ=1) can reduce alternating weak localizations sometimes observed in metal forming applications when shell elements get stretch-bended over small radii. This option currently works with shell element types 2, 4, and 16. A maximum number of 9 through thickness integration points is allowed for this method. A speed penalty of max. 15 % may be observed with this option.

***CONTROL_SOLID**

Purpose: Provides controls for solid element response.

VARIABLE**DESCRIPTION**

ESORT

Automatic sorting of tetrahedral and pentahedral elements to avoid use of degenerate formulations for these shapes. See *SECTION_SOLID.

EQ.0: No sorting (default)

EQ.1: Sort tetrahedron to type 10; pentahedron to type 15; cohesive pentahedron types 19 and 20 to types 21 and 22, respectively.

EQ.2: Sort tetrahedron to type 10; 1-point integrated pentahedron to type 115; fully integrated pentahedron to type 15; cohesive pentahedron types 19 and 20 to types 21 and 22, respectively.

EQ.3: Same as EQ.1 but also print switched elements in messag file

EQ.4: Same as EQ.2 but also print switched elements in messag file

| VARIABLE | DESCRIPTION |
|-----------------|---|
| FMATRX | <p>Default method used in the calculation of the deformation gradient matrix.</p> <p>EQ.1: Update incrementally in time. This is the default for explicit.</p> <p>EQ.2: Directly compute F. This is the default for implicit and implicit/explicit switching.</p> |
| NIPTETS | <p>Number of integration points used in the quadratic tetrahedron elements. Either 4 or 5 can be specified. This option applies to the types 4, 16, and 17 tetrahedron elements.</p> |
| SWLOCL | <p>Output option for stresses in solid elements used as spot welds with material *MAT_SPOTWELD. Affects elout, d3plot, d3part, etc.</p> <p>EQ.1: Stresses in global coordinate system (default)</p> <p>EQ.2: Stresses in element coordinate system</p> |
| PSFAIL | <p>Solid element erosion from negative volume is limited <i>only</i> to solid elements in the part set indicated by PSFAIL. This is similar to setting ERODE = 1 in *CONTROL_TIMESTEP except that it is not global.</p> <p>In other words, when PSFAIL is nonzero, the time-step-based criterion for erosion (TSMIN) applies to all solid elements (except formulations 11 and 12) while the negative volume criterion for erosion applies only to solids in part set PSFAIL.</p> |
| T10JTOL | <p>Tolerance for Jacobian in 4-point 10-noded quadratic tetrahedra (type 16). If the quotient between the minimum and maximum Jacobian values falls below this tolerance, a warning message is issued in the messag file. This is useful for tracking (badly shaped) elements that deteriorate convergence during implicit analysis; a value of 1.0 indicates a perfectly shaped element.</p> |
| ICOH | <p>Breaking LS-DYNA convention ICOH is interpreted digit-wise, namely as,</p> $\text{ICOH} = [\text{LK}] = \text{K} + 10 \times \text{L} .$ <p>The first digit, in the one's place, which we shall call K is interpreted as follows:</p> <p>K.EQ.0: No cohesive element deletion due to neighbor failure.</p> <p>K.EQ.1: Solid elements having ELFORM = 19 - 22 will be</p> |

| VARIABLE | DESCRIPTION |
|------------|--|
| | <p>eroded when neighboring shell or solid elements fail. Only works for nodewise connected parts, not tied contacts.</p> <p>The second digit, in the ten's place is, which we shall call L is interpreted as stated below. Note that if ICOH is less than 10 (having a single digit) then L defaults to zero.</p> <p>L.EQ.0: Default stable time step estimate, which is computed from the stiffness and the nodal masses of the top and bottom as with discrete elements.</p> <p>L.EQ.1: Most conservative (smallest) stable time step estimate. This method calculates mass by integrating the density.</p> <p>L.EQ.2: Intermediate stable time step estimate. Same as the default except reduced by a factor of $1/\sqrt{2}$ corresponding to halving the masses.</p> |
| TET13K | <p>Set to 1 to invoke a consistent tangent stiffness matrix for the pressure averaged tetrahedron (type 13). This feature is available only for the implicit integrator <i>and it is not supported in the MPP/MPI version</i>. This element type averages the volumetric strain over adjacent elements to alleviate volumetric locking; therefore, the corresponding material tangent stiffness should be treated accordingly. In contrast to a hexahedral mesh where a node usually connects to fewer than 8 elements, tetrahedral meshes offer no such regularity. Consequently, for nonlinear implicit analysis matrix assembly is computationally expensive, so this option is recommended only for linear or eigenvalue analysis to exploit the stiffness characteristics of the type 13 tetrahedron.</p> |
| PM1 – PM10 | <p>Components of a permutation vector for nodes that define the 10-node tetrahedron. The nodal numbering of 10-node tetrahedron elements is somewhat arbitrary. The permutation vector allows other numbering schemes to be used. Unless defined, this permutation vector is not used. PM1 – PM10 are unique numbers between 1 to 10 inclusive that reorders the input node ID's for a 10-node tetrahedron into the order used by LS-DYNA.</p> |

***CONTROL_SOLUTION**

Purpose: To specify the analysis solution procedure if thermal only or coupled thermal analysis is performed. Other solutions parameters including the vector length and NaN (not a number) checking can be set.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|-------|-------|-------|-------|---|---|
| Variable | SOLN | NLQ | ISNAN | LCINT | LCACC | NCDCF | | |
| Type | I | I | I | I | I | I | | |
| Default | 0 | 0 | 0 | 100 | 0 | 1 | | |

VARIABLE**DESCRIPTION**

SOLN

Analysis solution procedure:

EQ.0: Structural analysis only,

EQ.1: Thermal analysis only,

EQ.2: Coupled structural thermal analysis.

NLQ

Define the vector length used in solution. This value must not exceed the vector length of the system which varies based on the machine manufacturer. The default vector length is printed at termination in the `messag` file.

ISNAN

Flag to check for a NaN in the force and moment arrays after the assembly of these arrays is completed. This option can be useful for debugging purposes. A cost overhead of approximately 2% is incurred when this option is active.

EQ.0: No checking,

EQ.1: Checking is active.

LCINT

Number of equally spaced points used in curve (`*DEFINE_CURVE`) rediscretization. A minimum number of `LCINT = 100` is always used, i.e., only larger input values are possible. Curve rediscretization applies only to curves used in material models. Curves defining loads, motion, etc. are not rediscretized.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| LCACC | <p>Flag to truncate curves to 6 significant figures for single precision and 13 significant figures for double precision. The truncation is done after applying the offset and scale factors specified in *DEFINE_CURVE. Truncation is intended to prevent curve values from deviating from the input value, e.g., 0.7 being stored as 0.69999999. This small deviation was seen to have an adverse effect in a particular analysis using *MAT_083. In general, curve truncation is not necessary and is unlikely to have any effect on results.</p> <p>EQ.0: No truncation. NE.0: Truncate.</p> |
| NCDCF | <p>Global option to evaluate *DEFINE_CURVE_FUNCTION every NCDCF:th cycle.</p> |

*CONTROL

*CONTROL_SPH

*CONTROL_SPH

Purpose: Provide controls relating to SPH (Smooth Particle Hydrodynamics).

VARIABLE

DESCRIPTION

NCBS

Number of time steps between particle sorting.

BOXID

SPH approximations are computed inside a specified BOX. When a particle has gone outside the BOX, it is deactivated. This will save computational time by eliminating particles that no longer interact with the structure.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| DT | Death time. Determines when the SPH calculations are stopped. |
| IDIM | Space dimension for SPH particles: EQ.3: for 3D problems EQ.2: for 2D plane strain problems EQ.-2: for 2D axisymmetric problems (see Remark 2) |
| MEMORY | Defines the initial number of neighbors per particle (see Remark 1 below). |
| FORM | Particle approximation theory (Remark 2): EQ.0: default formulation EQ.1: renormalization approximation EQ.2: symmetric formulation EQ.3: symmetric renormalized approximation EQ.4: tensor formulation EQ.5: fluid particle approximation EQ.6: fluid particle with renormalization approximation EQ.7: total Lagrangian formulation EQ.8: total Lagrangian formulation with renormalization EQ.9: adaptive SPH formulation (ASPH) with anisotropic smoothing tensor (Remark 2 , (g)) EQ.10: renormalization approximation for adaptive SPH formulation (ASPH) with anisotropic smoothing tensor EQ.12: moving least-squares based formulation (Remark 2 , (e)) EQ.15: enhanced fluid formulation EQ.16: enhanced fluid formulation with renormalization |
| START | Start time for particle approximation. Particle approximations will be computed when time of the analysis has reached the value defined in START. |
| MAXV | Maximum value for velocity for the SPH particles. Particles with a velocity greater than MAXV are deactivated. A negative MAXV will turn off the velocity checking. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| CONT | <p>Flag for inter-part particle interaction by “particle approximation”:</p> <p>EQ.0: Particle approximation is used for computing inter-part particle interaction for all SPH parts (default).</p> <p>EQ.1: Particle approximation is not used for inter-part particle interaction, except as specified by the INTERACTION option of *SECTION_SPH. As an alternative to particle approximation, inter-part particle interaction can be accomplished using *DEFINE_SPH_TO_SPH_COUPLING.</p> |
| DERIV | <p>Time integration type for the smoothing length:</p> <p>EQ.0: $\frac{d}{dt} [h(t)] = \frac{1}{d} h(t) \nabla \cdot \mathbf{v}$, (default),</p> <p>EQ.1: $\frac{d}{dt} [h(t)] = \frac{1}{d} h(t) (\nabla \cdot \mathbf{v})^{1/3}$</p> |
| INI | <p>Computation of the smoothing length during the initialization:</p> <p>EQ.0: Bucket sort based algorithm (default, very fast).</p> <p>EQ.1: Global computation on all the particles of the model.</p> <p>EQ.2: Based on the mass of the SPH particle.</p> |
| ISHOW | <p>Display option for deactivated SPH particles:</p> <p>EQ.0: No distinction in active SPH particles and deactivated SPH particles when viewing in LS-PrePost.</p> <p>EQ.1: Deactivated SPH particles are displayed only as points and active SPH particles are displayed as spheres when Setting → SPH → Style is set to “smooth” in LS-PrePost.</p> |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| IEROD | <p>Deactivation control for SPH particles:</p> <p>EQ.0: Particles remain active. See Remark 3.</p> <p>EQ.1: SPH particles are partially deactivated and stress states are set to 0 when erosion criteria are satisfied. See Remark 3.</p> <p>EQ.2: SPH particles are totally deactivated and stress states are set to 0 when erosion criteria are satisfied. See Remark 3.</p> <p>EQ.3: SPH particles are partially deactivated and stress states are set to 0 when erosion criteria are satisfied. If an EOS is defined, the volumetric response is unaffected. See Remark 3.</p> |
| ICONT | <p>Controls contact behavior for deactivated SPH particles:</p> <p>EQ.0: Any contact defined for SPH remains active for deactivated particles.</p> <p>EQ.1: Contact is inactive for deactivated particles.</p> |
| IAVIS | <p>Defines artificial viscosity formulation for SPH elements (Remark 4):</p> <p>EQ.0: Monaghan type artificial viscosity formulation is used.</p> <p>EQ.1: Standard type artificial viscosity formulation from solid element is used (this option is not supported in SPH 2D and 2D axisymmetric elements).</p> |
| ISYMP | <p>Defines the percentage of original SPH particles used for memory allocation of SPH symmetric planes ghost nodes generation process (default is 100%). Recommended for large SPH particles models (value range 10~20) to control the memory allocation for SPH ghost particles with *BOUNDARY_SPH_SYMMETRY_PLANE keyword.</p> |
| ITHK | <p>Contact thickness option:</p> <p>EQ.0: The contact thickness is set to zero (default).</p> <p>EQ.1: The contact thickness is automatically calculated based on the volume of each SPH particle.</p> <p>This contact thickness calculation is ignored if a non-zero contact thickness for slave surface (SST) is provided by the contact card.</p> |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| ISTAB | Stabilization type, only used when IFORM = 12: EQ.0: Incremental stabilization (default). Adequate for most materials. EQ.1: Total stabilization. Only recommended for hyperelastic materials. |
| QL | Quasi-Linear coefficient, only used when IFORM = 12. See Remark 5 . |

Remark:

- 1. Memory.** MEMORY is used to determine the initial memory allocation for the SPH arrays. Its value can be positive or negative. If MEMORY is positive, memory allocation is dynamic such that the number of neighboring particles is initially equal to MEMORY but that number is subsequently allowed to exceed MEMORY as the solution progresses. If MEMORY is negative, memory allocation is static and |MEMORY| is the maximum allowed number of neighboring particles for each particle throughout the entire solution. Using this static memory option can avoid memory allocation problems.
- 2. Form.** The user has to be careful to pick the right FORM which depends upon the application. Below are some guidelines for selecting the FORM value:
 - a)** For most solid structure applications, FORM = 1 is recommended for more accurate results around the boundary area.
 - b)** For fluid or fluid-like material applications, FORM = 15 or 16 is recommended. FORM = 16 usually has better accuracy but requires more CPU time. Also note that formulations 15 and 16 include a smoothing of the pressure field and are, therefore, not recommended for materials with failure or problems with important strain localization.
 - c)** All SPH formulations with Eulerian kernel, that is, FORM with values 0 to 6, 15 and 16, can be used for large or extremely large deformation applications but will have tensile instability issues. FORM = 2 or 3 is not recommended for any case.
 - d)** All SPH formulations with Lagrangian kernel (FORM = 7 or 8) can be used to avoid tensile instability issue but they cannot endure very large deformations.

- e) For improved accuracy and tensile stability, a formulation based on moving least-squares (FORM = 12) is available. This formulation can be used for extremely large deformation applications, but entails a significant computational cost. FORM = 12 is available for MPP simulations only. It is strongly recommended to keep a constant smoothing length for this formulation, by setting HMIN = 1.0 and HMAX = 1.0 in *SECTION_SPH.
 - f) Only formulations 0, 1, 15 and 16 are implemented for 2D axisymmetric problems (IDIM = -2).
 - g) Form = 9, 10 are adaptive smoothed particle hydrodynamics formulation and the corresponding renormalization form with an anisotropic kernel (Eulerian kernel) whose axes evolve automatically to follow the mean particles spacing as it varies in time, space and direction based on the strain rate tensors. These forms need to go with *SECTION_SPH_ELLIPSE keyword and have better accuracy and stability than the standard SPH. These forms can be used for extremely large deformation problems and are available for 3D and SMP case only.
3. **Erosion.** The erosion criteria, which triggers particle deactivation when IEROD = 1, 2 or 3, may come from either the material model, from *MAT_ADD_EROSION, or from the ERODE field in *CONTROL_TIMESTEP.
- a) For IEROD = 0, SPH particles remain active. This option is generally not recommended when materials with erosion are used, as many material models will still reset the stress field to zero periodically. If an unaltered stress field is desired, simply remove the erosion criteria in the material model parameters.
 - b) For IEROD = 1, SPH particles are partially deactivated; that is, the stress states of the deactivated SPH particles will be set to 0, but these particles still remain in the domain integration for more stable results.
 - c) For IEROD = 2, SPH particles are totally deactivated, so the stress states will be set to 0 and the deactivated particles do not remain in the domain integration.
 - d) For IEROD = 3, SPH particles remain active. The deviatoric stress is set to 0. If an equation of state is used the volumetric response remains unaltered, otherwise the volumetric stress is set to 0 as well.
 - e) Deactivated particles can be distinguished from active particles by setting ISHOW = 1.
 - f) To disable contact for deactivated particles, set ICONT = 1.

4. **Artificial Viscosity.** The artificial viscosity for standard solid elements, which is active when AVIS = 1, is given by:

$$q = \rho l (Q_1 l \dot{\epsilon}_{kk}^2 - Q_2 a \dot{\epsilon}_{kk}) \quad \dot{\epsilon}_{kk} < 0$$

$$q = 0 \quad \dot{\epsilon}_{kk} \geq 0$$

where Q_1 and Q_2 are dimensionless input constants, which default to 1.5 and .06, respectively (see *CONTROL_BULK_VISCOSITY); l is a characteristic length given as the square root of the area in two dimensions and as the cube root of the volume in three; and a is the local sound speed. This formulation, which is consistent with solid artificial viscosity, has better energy balance for SPH elements.

For general applications, Monaghan type artificial viscosity is recommended since this type of artificial viscosity is specifically designed for SPH particles. The Monaghan type artificial viscosity, which is active when AVIS = 0, is defined as follows:

$$q = \begin{cases} \frac{-Q_2 \bar{c}_{ij} \phi_{ij} + Q_1 \phi_{ij}^2}{\bar{\rho}_{ij}} & v_{ij} x_{ij} < 0 \\ 0 & v_{ij} x_{ij} \geq 0 \end{cases}$$

where,

$$\phi_{ij} = \frac{h_{ij} v_{ij} x_{ij}}{|x_{ij}|^2 + \varphi^2}$$

$$\bar{c}_{ij} = 0.5(c_i + c_j)$$

$$\bar{\rho}_{ij} = 0.5(\rho_i + \rho_j)$$

$$h_{ij} = 0.5(h_i + h_j)$$

$$\varphi = 0.1h_{ij}$$

and Q_1/Q_2 are input constants. When using Monaghan type artificial viscosity,

it is recommended that the user set both Q_1 and Q_2 to 1.0 on either the *CONTROL_BULK_VISCOSITY or *HOURLASS keywords; see for example G. R. Liu.

5. **Quasi-Linear Coefficient.** The moving least-squares based formulation contains a quasi-linear approximation term to combine accuracy with stability in extremely large deformations simulations. The default value QL = 0.01 gives a good compromise between accuracy and stability in most cases. For greater accuracy, its value can be reduced to QL = 0.001 in simulations with small deformations, or increased to QL = 0.1 for extreme deformations, if instabilities are present.

***CONTROL_SPOTWELD_BEAM**

Purpose: Provides factors for scaling the failure force resultants of beam spot welds as a function of their parametric location on the contact segment and the size of the segment. Also, an option is provided to replace beam welds with solid hexahedron element clusters.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-------|--------|-------|-------|-------|--------|
| Variable | LCT | LCS | T_ORT | PRTFLG | T_OR5 | RPBHX | BMSID | ID_OFF |
| Type | I | I | I | I | I | I | I | I |
| Default | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

VARIABLE**DESCRIPTION**

| | |
|--------|---|
| LCT | Load curve ID for scaling the response in tension based on the shell element size. |
| LCS | Load curve ID for scaling the response in shear based on the shell element size. |
| T_ORT | Table ID for scaling the tension response (and shear response if T_OR5 = 0) based on the location of the beam node relative to the centroid of the shell. |
| PRTFLG | Set this flag to 1 to print for each spot weld attachment: the beam, node, and shell ID's, the parametric coordinates that define the constraint location, the angle used in the table lookup, and the three scale factors obtained from the load curves and table lookup. See Figure 12-89 . |

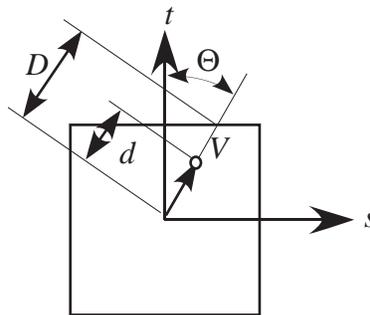

Figure 12-89. Definition of parameters for table definition.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| T_ORS | Optional table ID for scaling the shear response based on the location of the beam node relative to the centroid of the shell. |
| RPBHX | Replace each spot weld beam element with a cluster of RPBHX solid elements. The net cross-section of the cluster of elements is dimensioned to have the same area as the replaced beam. RPBHX may be set to 1, 4, or 8. When RPBHX is set to 4 or 8, a table is generated to output the force and moment resultants into the SWFORC file, if this file is active. This table is described by the keyword: *DEFINE_HEX_SPOTWELD_ASSEMBLY. The ID's of the beam elements are used as the cluster spot weld ID's so the ID's in the SWFORC file are unchanged. The beam elements are automatically deleted from the calculation, and the section and material data is automatically changed to be used with solid elements. See Figure 15-51 . |
| BMSID | Optional beam set ID defining the beam element ID's that are to be converted to hex assemblies. If zero, all spot weld beam elements are converted to hex assemblies. |
| ID_OFF | This optional ID offset applies if and only if BMSID is nonzero. Beams, which share part ID's with beams that are converted to hex assemblies, will be assigned new part ID's by adding to the original part ID the value of ID_OFF. If ID_OFF, is zero the new part ID for such beams will be assigned to be larger than the largest part ID in the model. |

Remarks:

The load curves and table provide a means of scaling the response of the beam spot welds to reduce any mesh dependencies for failure model 6 in *MAT_SPOTWELD. [Figure 12-90](#) shows such dependencies that can lead to premature spot weld failure. Separate scale factors are calculated for each of the beam's nodes. The scale factors s_T , s_S , s_{OT} , and s_{OS} are calculated using the load curves LCT, LCS, table T_ORI, and table T_ORS, respectively, and are introduced in the failure criteria,

$$\left[\frac{s_T s_{OT} \sigma_{rr}}{\sigma_{rr}^F(\dot{\epsilon}_{eff})} \right]^2 + \left[\frac{s_S s_{OS} \tau}{\tau^F(\dot{\epsilon}_{eff})} \right]^2 - 1 = 0$$

If a curve or table is given an ID of 0, its scale factor is set to 1.0. The load curves LCT and LCS are functions of the characteristic size of the shell element used in the time step calculation at the start of the calculation. The orientation table is a function of the spot weld's isoparametric coordinate location on the shell element. A vector $V=(s,t)$ is

defined from the centroid of the shell to the contact point of the beam's node. The arguments for the orientation table are the angle:

$$\Theta = \tan^{-1} \left[\frac{\min(|s|, |t|)}{\max(|s|, |t|)} \right],$$

and the normalized distance $\bar{d} = d/D = \max(|s|, |t|)$. See [Figure 12-89](#). The table is

periodic over a range of 0 (V aligned with either the s or t axis) to 45 degrees (V is along the diagonal of the element). The table is specified by the angle of V in degrees, ranging from 0 to 45, and the individual curves give the scale factor as a function of the normalized distance of the beam node, \bar{d} , for a constant angle.

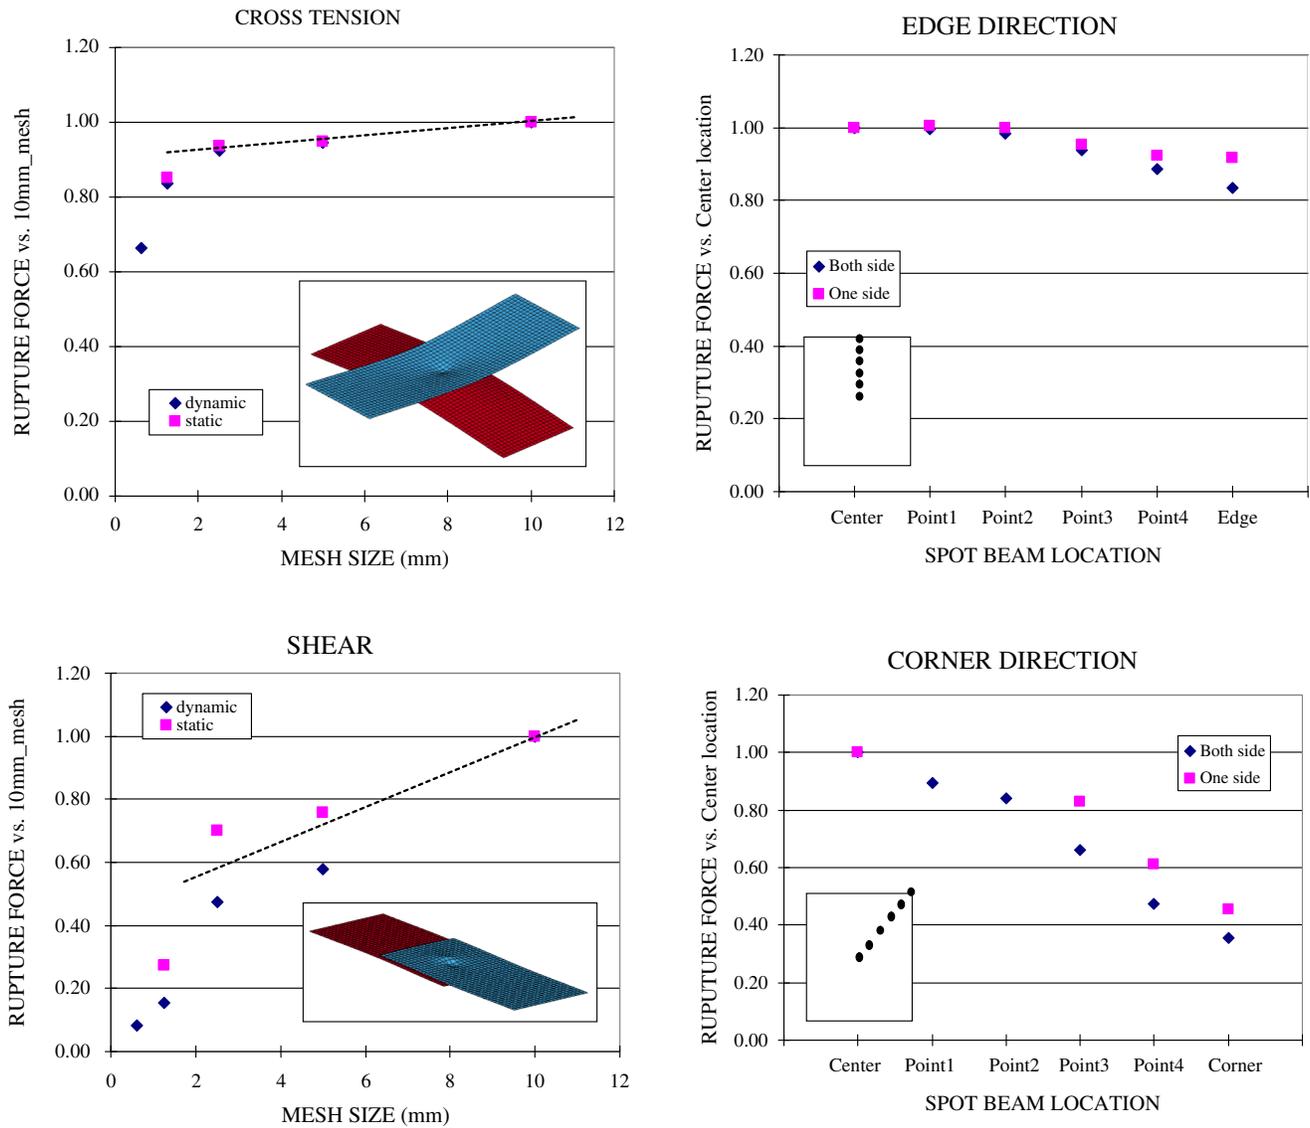

Figure 12-90 The failure force resultants can depend both on mesh size and the location of weld relative to the center of the contact segment

***CONTROL_START**

Purpose: Define the start time of analysis.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|---|---|---|---|---|---|---|
| Variable | BEGTIM | | | | | | | |
| Type | F | | | | | | | |

VARIABLE

DESCRIPTION

BEGTIM

Start time of analysis (default = 0.0). *Load curves are not shifted to compensate for the time offset.* Therefore, this keyword will change the results of any calculation involving time-dependent load curves.

*CONTROL

*CONTROL_STAGED_CONSTRUCTION

*CONTROL_STAGED_CONSTRUCTION

Purpose: Help break down analyses of construction processes into stages.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|------|------|-------|------------------|-------|--------|--------|
| Variable | TSTART | STGS | STGE | ACCEL | FACT | STREF | DORDEL | NOPDEL |
| Type | F | I | I | F | F | I | I | I |
| Default | 0. | 0 | 0 | 0.0 | 10 ⁻⁶ | 0 | 0 | 0 |

This card is optional.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|---|---|---|---|---|---|
| Variable | ITIME | | | | | | | |
| Type | I | | | | | | | |
| Default | 0 | | | | | | | |

VARIABLE

DESCRIPTION

| | |
|--------|--|
| TSTART | Time at start of analysis (normally leave blank). See Remark 5 . |
| STGS | Construction stage at start of analysis |
| STGE | Construction stage at end of analysis |
| ACCEL | Default acceleration for gravity loading |
| FACT | Default stiffness and gravity factor for parts before they are added |
| STREF | Reference stage for displacements in d3plot file |
| DORDEL | Dormant part treatment in d3plot file (see Remark 7): EQ.0: Parts not shown when dormant (flagged as “deleted”). EQ.1: Parts shown normally when dormant. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| NOPDEL | Treatment of pressure loads on deleted elements (see Remark 8): EQ.0: Pressure loads automatically deleted. EQ.1: No automatic deletion. |
| ITIME | Treatment of “Real Time” on *DEFINE_CONSTRUCTION_STAGES (see Remark 9): EQ.0: Real Time is ignored. EQ.1: Time in output files (d3plot, d3thdt, binout...) is converted to Real Time. |

Remarks:

1. **Related Keywords.** See also *DEFINE_CONSTRUCTION_STAGES and *DEFINE_STAGED_CONSTRUCTION_PART.
2. **Re-Running Analysis.** The staged construction options offer flexibility to carry out the whole construction simulation in one analysis or to run it stage by stage. Provided that at least one construction stage is defined (*DEFINE_CONSTRUCTION_STAGES), a dynain file will be written at the end of each stage (file names are end_stage001_dynain, etc). These contain node and element definitions and the stress state; the individual stages can then be re-run without re-running the whole analysis. To do this, make a new input file as follows:
 - Copy the original input file, containing *DEFINE_CONSTRUCTION_STAGES and *DEFINE_STAGED_CONSTRUCTION_PART.
 - Delete node and element definitions as these will be present in the dynain file (*NODE, *ELEMENT_SOLID, *ELEMENT_SHELL, and *ELEMENT_BEAM).
 - Delete any *INITIAL cards; the initial stresses in the new analysis will be taken from the dynain file.
 - On *CONTROL_STAGED_CONSTRUCTION set STGS to start at the desired stage
 - Add an *INCLUDE statement referencing, for example, end_stage002_dynain if starting the new analysis from Stage 3.
 - Move or copy the dynain file into the same directory as the new input file.

3. **Starting and End Stages.** When STGS is > 1 the analysis starts at a non-zero time (the start of stage STGS). In this case a dynain file must be included to start the analysis from the stress state at the end of the previous stage. The end time for stage STGE overrides the termination time on *CONTROL_TERMINATION. A new dynain file will be written at the end of all stages from STGS to STGE.

If STGS > 1 and elements have been deleted in a previous stage, these elements will be absent from the new analysis and should not be referred to (e.g. *DATABASE_HISTORY_SOLID) in the new input file.

4. **Input Simplification.** ACCEL and FACT are used with *STAGED_CONSTRUCTION_PART for simpler input definition of the parts present at different construction stages.
5. **Start Time.** TSTART can be used to set a non-zero start time (again, assuming a compatible dynain file is included). This option is used only if construction stages have not been defined.
6. **Reference Stage.** STREF allows the user to set a construction stage at the start of which displacements are considered to be zero so that initial analysis stages that achieve a pre-construction equilibrium do not contribute to contour plots of displacement. The current coordinates are not modified, only the “initial geometry” coordinates in the d3plot file. If this analysis starts from a stage later than STREF, the reference geometry will be taken from the dynain file that was written at the end of the stage previous to STREF. This dynain file must be in the same directory as the current model for this process to occur. This feature is not available in MPP.
7. **Dormant Parts.** By default, parts for which *DEFINE_STAGED_CONSTRUCTION_PART is defined are flagged as “deleted” in the d3plot file at time-states for which the part is not active (that is, STGA has not yet been reached). Parts that are deleted because STGR has been reached are also flagged as “deleted.” When animating the results, the parts should appear as they become active and disappear as they are deleted. If DORDEL is non-zero, inactive parts (before STGA) are shown normally. The parts are still shown as deleted after STGR is reached.
8. **Pressure Load Segments.** By default, pressure load “segments” are automatically deleted by LS-DYNA if they share all four nodes with a deleted solid or shell element. In staged construction, the user may want to apply a pressure load to the surface of an element, A, that is initially shared with an element, B, where B is deleted during the calculation. For example, B may be in a layer of soil that is excavated, leaving A as the new top surface. The default scheme would delete the pressure segment when B is removed, despite

the fact that A is still present. NOPDEL instructs LS-DYNA to skip the automatic deletion of pressure segments, irrespective of whether the elements have been deleted due to staged construction or material failure. The user must then ensure that pressure loads are not applied to nodes no longer supported by an active element.

9. **Real Time.** Construction processes that in real life take days, weeks or months may be modelled in seconds of analysis time using a “time acceleration” method. For example, one second of analysis time might represent ten days of real time. The speed-up factor might differ at different stages of the analysis. When presenting results, it can be advantageous to show real time on the plots and graphs rather than the analysis time used in LS-DYNA’s calculations. To do this, set ITIMES to 1, and set RTS and RTE (see optional fields RTS and RTE on *DEFINE_CONSTRUCTION_STAGES) to the real time at the start and end of each stage. This feature has no effect on the calculations as it changes only the times shown in the d3plot, d3thdt and binout files.

***CONTROL_STEADY_STATE_ROLLING**

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|--------|------|-------|---|---|---|
| Variable | IMASS | LCDMU | LCDMUR | IVEL | SCL_K | | | |
| Type | I | I | I | I | I | | | |
| Default | 0 | 0 | 0 | 0 | ↓ | | | |

VARIABLE**DESCRIPTION**

IMASS

Inertia switching flag:

EQ.0: include inertia during an implicit dynamic simulation.

EQ.1: treat steady state rolling subsystems as quasi-static during implicit dynamic simulations.

LCDMU

Optional load curve for scaling the friction forces in contact.

LCDMUR

Optional load curve for scaling the friction forces in contact during dynamic relaxation. If LCDMUR isn't specified, LCDMU is used.

IVEL

Velocity switching flag:

EQ.0: eliminate the steady state rolling body forces and set the velocities of the nodes after dynamic relaxation.

EQ.1: keep the steady state rolling body forces after dynamic relaxation instead of setting the velocities.

SCL_K

Scale factor for the friction stiffness during contact loading and unloading. The default values are 1.0 and 0.01 for explicit and implicit, respectively. Any scaling applied here applies only to contact involving the subsystem of parts defined for steady state rolling.

Remarks:

1. **Quasi-Static.** Treating the steady state rolling subsystems as quasi-static during an implicit simulation may eliminate vibrations in the system that are not of interest and is generally recommended.

2. **Scaling Friction and Convergence.** Ramping up the friction by scaling it with LCDMU and LCDMUR may improve the convergence behavior of implicit calculations. The values of the load curves should be 0.0 at initial contact and ramp up smoothly to a value of 1.0.
3. **Steady State Rolling Body Forces.** After dynamic relaxation, the default behavior is to initialize the nodes with the velocities required to generate the body forces on elements and remove the body forces. This initialization is skipped, and the body forces retained, after dynamic relaxation if IVEL = 1.
4. **Friction Stiffness Scale Factor.** The friction model in contact is similar to plasticity, where there is an elastic region during the loading and unloading of the friction during contact. The elastic stiffness is scaled from the normal contact stiffness. For implicit calculations, the default scale factor is 0.01, which results in long periods of time being required to build the friction force, and, in some cases, oscillations in the contact forces. A value between 10 and 100 produces smoother solutions and a faster build-up and decay of the friction force as the tire velocity or slip angle is varied, allowing a parameter study to be performed in a single run.

***CONTROL_STRUCTURED_{OPTION}**

Available options include:

<BLANK>

TERM

Purpose: Write out an LS-DYNA structured input deck that is largely or wholly equivalent to the keyword input deck. This option may be useful in debugging errors that occur during processing of the input file, particularly if error messages of the type “*** ERROR ##### (STR + ####)” are written. The name of the structured input deck is “dyna.str”.

Not all LS-DYNA features are supported in structured input format. Some data such as load curve numbers will be output in an internal numbering system.

If the TERM option is activated, termination will occur after the structured input deck is written.

Adding “outdeck = s” to the LS-DYNA execution line serves the same purpose as including *CONTROL_STRUCTURED in the keyword input deck.

***CONTROL_SUBCYCLE_{K}_{L}** or
***CONTROL_SUBCYCLE_{OPTION}**

Available options for subcycling first form with K and L

$$K, L \in \{<BLANK>, 1, 2, 4, 8, 16, 32, 64\}$$

Available options for multiscale (*OPTION*) include:

<BLANK>

MASS_SCALED_PART

MASS_SCALED_PART_SET

Purpose: This keyword is used to activate subcycling or mass scaling (multiscale). The common characteristic of both methods is that the time step varies from element to element, thereby eliminating unnecessary stepping on more slowly evolving portions of the model. These techniques are suited for reducing the computational cost for models involving large spatial variation in mesh density and/or material characteristics.

Subcycling is described in the LS-DYNA Theory Manual and in detail in Borrvall et.al. [2014] and may be seen as an alternative to using selective mass scaling, see the keyword ***CONTROL_TIMESTEP**.

This keyword comes in two variations:

1. **Subcycling.** Plain subcycling is activated by the ***CONTROL_SUBCYCLE_{K}_{L}** variant of this keyword. This form of the card should *not* be included more than once. It may be used in conjunction with mass scaling to limit the time step characteristics.

For subcycling, time steps for integration are determined automatically from the characteristic properties of the elements in the model, with the restriction that the ratio between the largest and smallest time step is limited by K . Furthermore, L determines the relative time step at which external forces such as contacts and loads are calculated

For example, ***CONTROL_SUBCYCLE_16_4** limits the largest explicit integration time step to at most 16 times the smallest. Contact forces are evaluated every 4 time steps. The defaults are $K = 16$ and $L = 1$, and L cannot be specified larger than K . This option may be used without mass scaling activated but internally elements may still be slightly mass scaled to maintain computational efficiency.

2. **Mass Scaling/Multiscale.** For a multiscale simulation, mass scaling is mandatory and the time steps are directly specified in the input. The specified

parts (see the PID field) or part sets (see the PSID field) run at the time step specified in the TS field. All other elements evolve with a time step set by $|DT2MS|$, which is set on *CONTROL_TIMESTEP card.

This feature was motivated by automotive crash simulation, wherein it is common for a small subset of *solid* elements to limit the time step size. With this card the finely meshed parts (consisting of solid elements) can be made to run with a smaller time step through mass scaling so that the rest of the vehicle can run with a time step size of $|DT2MS|$.

Part Card. Additional card for the MASS_SCALED_PART and MASS_SCALED_PART_SET keyword options. Provide as many cards as necessary. Input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|------|---|---|---|---|---|---|
| Variable | PID/PSID | TS | | | | | | |
| Type | I | F | | | | | | |
| Default | none | none | | | | | | |

VARIABLE**DESCRIPTION**

PID/PSID

Part ID or part set ID if the SET option is specified.

TS

Time step size at which mass scaling is invoked for the PID or PSID

***CONTROL_TERMINATION**

Purpose: Stop the job.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|-------|--------|---------|-------|---|---|
| Variable | ENDTIM | ENDCYC | DTMIN | ENDENG | ENDMAS | NOSOL | | |
| Type | F | I | F | F | F | I | | |
| Default | 0.0 | 0 | 0.0 | 0.0 | 1.0E+08 | 0 | | |
| Remarks | 1 | | 2 | | | | | |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| ENDTIM | Termination time. Mandatory. |
| ENDCYC | Termination cycle. The termination cycle is optional and will be used if the specified cycle is reached before the termination time. Cycle number is identical with the time step number. |
| DTMIN | Reduction (or scale) factor to determine minimum time step, t_{\min} , where $t_{\min} = dt_{\text{start}} \times \text{DTMIN}$ and dt_{start} is the initial step size determined by LS-DYNA. When the time step drops to t_{\min} , LS-DYNA terminates with a restart dump. See the exception described in Remark 2 . |
| ENDENG | Percent change in energy ratio for termination of calculation. If undefined, this option is inactive. |
| ENDMAS | Percent change in the total mass for termination of calculation. This option is relevant if and only if mass scaling is used to limit the minimum time step size; see *CONTROL_TIMESTEP field DT2MS. |
| NOSOL | Flag for a non-solution run, that is, normal termination directly after initialization. EQ.0: off (default), EQ.1: on. |

Remarks:

1. **Displacement Termination.** Termination by displacement may be defined in the *TERMINATION section.
2. **Erosion.** If the erosion flag on *CONTROL_TIMESTEP is set (ERODE = 1), then solid elements and thick shell elements whose time step falls below t_{min} will be eroded and the analysis will continue. This time-step-based failure option is not recommended when solid formulations 11 or 12 are included in the model. Furthermore, when PSFAIL in *CONTROL_SOLID is nonzero, regardless of the value of ERODE, then all solid elements excepting those with formulation 11 or 12, whose time step falls below t_{min} will be eroded and the analysis will continue. This time-step-based erosion of solids due to a nonzero PSFAIL is not limited to solids in part set PSFAIL. Only the negative-volume-based erosion criterion is limited to solids in part PSFAIL.

***CONTROL_THERMAL_EIGENVALUE**

Purpose: Compute eigenvalues of thermal conductance matrix for model evaluation purposes.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | NEIG | | | | | | | |
| Type | I | | | | | | | |
| Default | 0 | | | | | | . | . |

VARIABLE**DESCRIPTION**

NEIG

Number of eigenvalues to compute:

EQ.0: No eigenvalues are computed.

GT.0: Compute NEIG eigenvalues of each thermal conductance matrix.

Remarks:

1. **Feature Description.** This feature causes LS-DYNA to compute NEIG eigenvalues for each thermal conductance matrix. This tool is for model evaluation, so only a small number of thermal time steps, such as 1, should be used with this feature.

*CONTROL

*CONTROL_THERMAL_NONLINEAR

*CONTROL_THERMAL_NONLINEAR

Purpose: Set parameters for a nonlinear thermal or coupled structural/thermal analysis. The control card, *CONTROL_SOLUTION, is also required.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|------------|--------|--------|--------|--------|---|
| Variable | REFMAX | TOL | DCP | LUMPBC | THLSTL | NLTHPR | PHCHPN | |
| Type | I | F | F | I | F | I | F | |
| Default | 10 | 1.e-04 | 1.0 or 0.5 | 0 | 0. | 0 | 100. | |

VARIABLE

DESCRIPTION

REFMAX

Maximum number of matrix reformations per time step:
EQ.0: set to 10 reformations.

TOL

Convergence tolerance for temperature:
EQ.0.0: set to 1000 * machine roundoff.

DCP

Divergence control parameter:
steady state problems $0.3 \leq DCP \leq 1.0$ default 1.0
transient problems $0.0 < DCP \leq 1.0$ default 0.5

LUMPBC

Lump enclosure radiation boundary condition. LUMPBC = 1 activates a numerical method to damp out anomalous temperature oscillations resulting from very large step function boundary conditions. This option is not generally recommended.
EQ.0: off (default)
EQ.1: on

THLSTL

Line search convergence tolerance:
EQ.0.0: No line search
GT.0.0: Line search convergence tolerance

| VARIABLE | DESCRIPTION |
|-----------------|--|
| NLTHPR | Thermal nonlinear print out level: EQ.0: No print out EQ.1: Print convergence parameters during solution of nonlinear system |
| PHCHPN | Phase change penalty parameter: EQ.0.0: Set to default value 100. GT.0.0: Penalty to enforce constant phase change temperature |

***CONTROL_THERMAL_SOLVER**

Purpose: Set options for the thermal solution in a thermal only or coupled structural-thermal analysis. The control card, *CONTROL_SOLUTION, is also required.

Card Summary:

Card 1. This card is required.

| | | | | | | | |
|-------|-------|--------|-------|-----|--------|-------|-----|
| ATYPE | PType | SOLVER | CGTOL | GPT | EQHEAT | FWORK | SBC |
|-------|-------|--------|-------|-----|--------|-------|-----|

Card 2a. This card is optional. It is only read when SOLVER ≠ 17.

VARIABLE**DESCRIPTION**

ATYPE

Thermal analysis type:

EQ.0: steady state analysis (see [Remark 5](#))EQ.1: transient analysis (see [Remark 4](#))

| VARIABLE | DESCRIPTION |
|-----------------|--|
| PTYPE | <p>Thermal problem type: (see *CONTROL_THERMAL_NONLINEAR if nonzero)</p> <p>EQ.0: linear problem,</p> <p>EQ.1: nonlinear problem with material properties evaluated at gauss point temperature.</p> <p>EQ.2: nonlinear problem with material properties evaluated at element average temperature.</p> |
| SOLVER | <p>Thermal analysis solver type (see Remark 3):</p> <p>EQ.1: using solver 11 (enter -1 to use the old ACTCOL solver),</p> <p>EQ.2: nonsymmetric direct solver,</p> <p>EQ.3: diagonal scaled conjugate gradient iterative (default),</p> <p>EQ.4: incomplete choleski conjugate gradient iterative,</p> <p>EQ.5: nonsymmetric diagonal scaled bi-conjugate gradient</p> <p>For MPP executables (see Remark 1):</p> <p>EQ.11: symmetric direct solver (see Remark 2),</p> <p>EQ.12: diagonal scaling (default for MPP) conjugate gradient iterative,</p> <p>EQ.13: symmetric Gauss-Siedel conjugate gradient iterative,</p> <p>EQ.14: SSOR conjugate gradient iterative,</p> <p>EQ.15: ILDLT0 (incomplete factorization) conjugate gradient iterative,</p> <p>EQ.16: modified ILDLT0 (incomplete factorization) conjugate gradient iterative.</p> <p>For Conjugate Heat transfer problems:</p> <p>EQ.17: GMRES solver.</p> |
| CGTOL | <p>Convergence tolerance for SOLVER = 3 and 4.</p> <p>EQ.0.0: use default value of 10^{-4} for single precision or 10^{-6} for double precision</p> |
| GPT | <p>Number of Gauss points to be used in the solid elements:</p> <p>EQ.0: use default value 8,</p> <p>EQ.1: one point quadrature is used.</p> |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| EQHEAT | Mechanical equivalent of heat (see Remark 11). EQ.0.0: default value 1.0, LT.0.0: designates a load curve number for EQHEAT as a function of time. |
| FWORK | Fraction of mechanical work converted into heat. EQ.0.0: use default value 1.0. |
| SBC | Stefan Boltzmann constant. Value is used with enclosure radiation surfaces; see *BOUNDARY_RADIATION_... LT.0.0: use a smoothing algorithm when calculating view factors to force the row sum = 1. |

| Card 2a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|-------------------|------------------|-----------|---|---|-----|
| Variable | MSGLVL | MAXITR | ABSTOL | RELTOL | OMEGA | | | TSF |
| Type | I | I | F | F | F | | | F |
| Default | 0 | 500 | 10 ⁻¹⁰ | 10 ⁻⁶ | 1.0 or 0. | | | 1. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| MSGLVL | Output message level (For SOLVER > 10) EQ.0: no output (default), EQ.1: summary information, EQ.2: detailed information, use only for debugging. |
| MAXITR | Maximum number of iterations. For SOLVER > 11. EQ.0: use default value 500, |
| ABSTOL | Absolute convergence tolerance. For SOLVER > 11. EQ.0.0: use default value 10 ⁻¹⁰ |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| RELTOL | Relative convergence tolerance. Replaces CGTOL for SOLVER > 11. EQ.0.0: use default value 10^{-6} |
| OMEGA | Relaxation parameter omega for SOLVER 14 and 16. EQ.0.0: use default value 1.0 for Solver 14, use default value 0.0 for Solver 16. |
| TSF | Thermal Speedup Factor. This factor multiplies all thermal parameters with units of time in the denominator (e.g., thermal conductivity, convection heat transfer coefficients). It is used to artificially time scale the problem. Its main use is in metal stamping. If the velocity of the stamping punch is artificially increased by 1000, then set TSF = 1000 to scale the thermal parameters. |

| Card 2b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|------------|-----------|--------|---|---|---|
| Variable | MSGLVL | NINNER | ABSTOL | RELTOL | NOUTER | | | |
| Type | I | I | F | F | I | | | |
| Default | 0 | 100 | 10^{-10} | 10^{-6} | 100 | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| MSGLVL | Output message level (For SOLVER > 10) EQ.0: no output (default), EQ.1: summary information, EQ.2: detailed information, use only for debugging. |
| NINNER | Number of inner iterations for GMRES solve |
| ABSTOL | Absolute convergence tolerance. For SOLVER > 11. EQ.0.0: use default value 10^{-10} |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| RELTOL | Relative convergence tolerance. Replaces CGTOL for SOLVER > 11. EQ.0.0: use default value 10^{-6} |
| NOUTER | Number of outer iterations for GMRES solve |

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|------|--------|---|---|---|---|---|
| Variable | MXDMP | DTVF | WARDEN | | | | | |
| Type | I | F | I | | | | | |
| Default | 0 | 0. | 0 | | | | | . |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| MXDMP | Matrix Dumping for SOLVER > 11 EQ.0: No Dumping GT.0: Dump using ASCII format every MXDMP time steps. LT.0: Dump using binary format every MXDMP time steps. |
| DTVF | Time interval between view factor updates. |
| WARDEN | Variable thermal density. This parameter is only applicable for solid elements in a coupled thermal-stress problem. Setting this parameter will adjust the material thermal density in the thermal solver to account for very large volume changes when using an EOS or large coefficient of thermal expansion. For most applications, the default value, WARDEN = 0, should be used. EQ.0: use constant density (default) EQ.1: modify thermal density to account for volume change when using an EOS. EQ.2: modify thermal density to account for volume change when using a large coefficient of expansion. |

Remarks:

1. **Solver Availability in MPP.** Solvers 1, 2, 3 and 4 are only for SMP environments. Solvers 11, 12, 13, 14, 15 and 16 are for SMP and MPP.
2. **Recommended Direct Solver.** Solver 11 is the preferred direct solver. Solver 11 uses sparse matrix storage and requires much less memory than Solver 1.
3. **Direct versus Iterative Solver.** Use of a direct solver (e.g., SOLVER = 1, 2 or 11) is usually less efficient than using an iterative solver (SOLVER = 3, 4, 12, 13, 14, 15 or 16). Consider using a direct solver to get the model running and then switch to an iterative solver to decrease execution time (particularly for large models). Direct solvers should be used when experiencing slow or no convergence.
4. **Transient Problems.** For transient problems, diagonal scaling conjugate gradient (SOLVER = 3 or 12) should be adequate.
5. **Steady State Problems.** For steady state problems, convergence may be slow or unacceptable, so consider using direct solver (SOLVER = 1, 2 or 11) or a more powerful preconditioner (SOLVER = 4, 13, 14, 15 or 16).
6. **Solvers 13 & 14.** Solver 13 (symmetric Gauss-Seidel) and solver 14 (SSOR) are related. When OMEGA = 1.0, solver 14 is equivalent to solver 13. The optimal omega value for SSOR is problem dependent but lies between 1.0 and 2.0.
7. **Solvers 15 & 16.** Solver 15 (incomplete LDLT0) and solver 16 (modified incomplete LDLT0) are related. Both are no-fill factorizations that require one extra n-vector of storage. The sparsity pattern of the preconditioner is exactly the same as that of the thermal stiffness matrix. Solver 16 uses the relaxation parameter OMEGA. The optimal OMEGA value is problem dependent, but lies between 0.0 and 1.0.
8. **Solver 17.** The GMRES solver has been developed as an alternative to the direct solvers in cases where the structural thermal problem is coupled with the fluid thermal problem in a monolithic approach using the ICFD solver. A significant gain of calculation time can be observed when the problem reaches 1M elements.
9. **Completion Conditions for Solvers 12 – 15.** Solvers 12, 13, 14, 15 and 16 terminate the iterative solution process when (1) the number of iterations exceeds MAXITR or (2) the 2-norm of the residual drops below:
$$\text{ABSTOL} + \text{RELTOL} \times 2\text{-norm of the initial residual.}$$
10. **Debug Data.** Solvers 11 and up can dump the thermal conductance matrix and right-hand-side using the same formats as documented under *CON-

TROL_IMPLICIT_SOLVER. If this option is used, files beginning with T_ will be generated.

11. **Unit Conversion Factor.** EQHEAT is a unit conversion factor. EQHEAT converts the mechanical unit for work into the thermal unit for energy according to,

$$\text{EQHEAT} \times [\text{work}] = [\text{thermal energy}]$$

However, it is recommended that a consistent set of units be used with EQHEAT set to 1.0. For example, when using SI,

$$[\text{work}] = 1\text{Nm} = [\text{thermal energy}] = 1\text{J} \Rightarrow \text{EQHEAT} = 1.$$

***CONTROL_THERMAL_TIMESTEP**

Purpose: Set time step controls for the thermal solution in a thermal only or coupled structural/thermal analysis. This card requires that the deck also include *CONTROL_SOLUTION, and, *CONTROL_THERMAL_SOLVER needed.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

| Variable | TS | TIP | ITS | TMIN | TMAX | DTEMP | TSCP | LCTS |
| Type | I | F | F | F | F | F | F | I |
| Default | 0 | 0.5 | none | - | - | 1.0 | 0.5 | 0 |

VARIABLE**DESCRIPTION**

| | |
|------|---|
| TS | Time step control: EQ.0: fixed time step, EQ.1: variable time step (may increase or decrease). |
| TIP | Time integration parameter. See Remark 1 for details. EQ.0.5: Crank-Nicholson scheme, EQ.1.0: fully implicit (default). |
| ITS | Initial thermal time step |
| TMIN | Minimum thermal time step: EQ.0.0: set to structural explicit time step. LT.0.0: curve ID = (-TMIN) gives minimum thermal time step size as function of time. The load curve defines pairs (thermal time breakpoint, new minimum time step). See Remark 2 . |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| TMAX | <p>Maximum thermal time step:</p> <p>EQ.0.0: set to 100 * structural explicit time step.</p> <p>LT.0.0: curve ID = (-TMAX) gives maximum thermal time step size as function of time. The load curve defines pairs (thermal time breakpoint, new minimum time step). The time step will be adjusted to hit the time breakpoints exactly. See Remark 2.</p> |
| DTEMP | <p>Maximum temperature change in each time step above which the thermal time step will be decreased:</p> <p>EQ.0.0: set to a temperature change of 1.0.</p> <p>LT.0.0: curve ID = (-DTEMP) gives maximum temperature change as function of time. The load curve defines pairs (thermal time breakpoint, new temperature change). See Remark 2.</p> |
| TSCP | <p>Time step control parameter. The thermal time step is decreased by this factor if convergence is not obtained. $0. < TSCP < 1.0$:</p> <p>EQ.0.0: set to a factor of 0.5.</p> |
| LCTS | <p>LCTS designates a load curve number which defines data pairs of (thermal time breakpoint, new time step). The time step will be adjusted to hit the time breakpoints exactly. After the time breakpoint, the time step will be set to the 'new time step' ordinate value in the load curve.</p> |

Remarks:

- 1. Time integration parameter.** TIP is relevant only to a transient analysis and is ignored for a steady state analysis. The only two accepted values that make mathematical sense are TIP=0.5 or TIP=1. TIP=0.5 is the classical Crank-Nicolson method, which is mathematically more accurate than TIP=1 and is unconditionally stable in time, but a plot of nodal temperature vs. time can be oscillatory, especially in a nonlinear problem. The oscillations decrease with time. TIP=1.0 is the classical implicit method, which is also unconditionally stable and has the benefit that there are no oscillations of nodal temperature vs time.
- 2. Time step size control.** If automatic time step size control in combination with load curve definitions of the limits (dtmin, dtmax, dtemp), the time step is

adjusted to hit the breakpoints in the curves exactly. The time stepping algorithm ensures that the step size of the last time step before the breakpoint is not smaller than 50 % of the previous one. If necessary the sizes of the last two time steps before the breakpoint are averaged.

***CONTROL_TIMESTEP**

Purpose: Set structural time step size control using different options.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|------|---------|-------|------|-------|-------|
| Variable | DTINIT | TSSFAC | ISDO | TSLIMIT | DT2MS | LCTM | ERODE | MS1ST |
| Type | F | F | I | F | F | I | I | I |
| Default | ↓ | ↓ | 0 | 0.0 | 0.0 | 0 | 0 | 0 |

This card is optional.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|----------|------|---|---|------|---|---|
| Variable | DT2MSF | DT2MSLC | IMSC | | | RMSC | | |
| Type | F | I | I | | | F | | |
| Default | not used | not used | 0 | | | 0.0 | | |

VARIABLE**DESCRIPTION**

DTINIT

Initial time step size:

EQ.0.0: LS-DYNA determines initial step size.

TSSFAC

Scale factor for computed time step (old name SCFT). See [Remark 1](#) below. (Default = 0.90; if high explosives or non-reflecting boundaries are used, the default is lowered to 0.667).

ISDO

Basis of time size calculation for 4-node shell elements. 3-node shells use the shortest altitude for options 0,1 and the shortest side for option 2. This option has no relevance to solid elements, which use a length based on the element volume divided by the largest surface area.

EQ.0: characteristic length is given by

$$\frac{\text{area}}{\min(\text{longest side, longest diagonal})}$$

| VARIABLE | DESCRIPTION |
|----------|-------------|
|----------|-------------|

EQ.1: characteristic length is given by

$$\frac{\text{area}}{\text{longest diagonal}}$$

EQ.2: based on bar wave speed and,

$$\max \left[\text{shortest side}, \frac{\text{area}}{\min(\text{longest side}, \text{longest diagonal})} \right]$$

WARNING: Option 2 can give a much larger time step size that can lead to instabilities in some applications, especially when triangular elements are used.

EQ.3: This feature is currently unavailable. Time step size is based on the maximum eigenvalue. This option is okay for structural applications where the material sound speed changes slowly. The cost related to determining the maximum eigenvalue is significant, but the increase in the time step size often allows for significantly shorter run times without using mass scaling.

TSLIMIT

Shell element minimum time step assignment, TSLIMIT. When a shell controls the time step, element material properties (moduli *not* masses) will be modified such that the time step does not fall below the assigned step size. This option is applicable only to shell elements using material models:

*MAT_PLASTIC_KINEMATIC,

*MAT_POWER_LAW_PLASTICITY,

*MAT_STRAIN_RATE_DEPENDENT_PLASTICITY,

*MAT_PIECE-WISE_LINEAR_PLASTICITY.

WARNING: This so-called stiffness scaling option is NOT recommended. The DT2MS option below applies to all materials and element classes and is preferred.

If both TSLIMIT and DT2MS below are active and if TSLIMIT is input as a positive number, then TSLIMIT defaults to 10⁻¹⁸, thereby disabling it.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | If TSLIMIT is negative and less than DT2MS , then TSLIMIT is applied prior to the mass being scaled. If DT2MS exceeds the magnitude of TSLIMIT, then TSLIMIT is set to 10^{-18} . |
| DT2MS | <p>Time step size for mass scaled solutions. (Default = 0.0)</p> <p>GT.0.0: Positive values are for quasi-static analyses or time history analyses where the inertial effects are insignificant.</p> <p>LT.0.0: $TSSFAC \times DT2MS$ is the minimum time step size permitted and mass scaling is done if and only if it is necessary to meet the Courant time step size criterion. This option can be used in transient analyses if the mass increases remain insignificant. See also the variable MS1ST below and the *CONTROL_TERMINATION variable ENDMAS.</p> <div style="border: 1px solid black; padding: 10px; margin: 10px 0;"> <p>WARNING: Superelements from, *ELEMENT_DIRECT_MATRIX_INPUT, are not mass scaled; consequently, DT2MS does not affect their time step size. In this case an error termination will occur, and DT2MS will need to be reset to a smaller value.</p> </div> |
| LCTM | Load curve ID that limits the maximum time step size (optional). This load curve defines the maximum time step size permitted as a function of time. If the solution time exceeds the final time value defined by the curve, the computed step size is used. If the time step size from the load curve is exactly zero, the computed time step size is also used. |
| ERODE | <p>Erosion flag for solids and thick shells.</p> <p>EQ.0: Calculation will terminate if time step drops to t_{min} (see *CONTROL_TERMINATION).</p> <p>EQ.1: Solids and thick shells whose time step drops to t_{min} (see *CONTROL_TERMINATION) will erode, and SPH particles whose time step drops to t_{min} will be deactivated.</p> <p>ERODE = 1 and $t_{min} > 0$ also invokes erosion of any solid element whose volume becomes negative, thereby preventing</p> |

| VARIABLE | DESCRIPTION |
|----------|--|
| MS1ST | <p>termination of the analysis due to negative volume. The effect of $ERODE = 1$ on erosion due to negative value is superseded by a nonzero PSFAIL in *CONTROL_SOLID. PSFAIL serves to limit solid erosion based on negative volume to solids in part set PSFAIL.</p> <p>Option for mass scaling that applies when $DT2MS < 0$.</p> <p>EQ.0: (Default) Mass scaling is considered throughout the analysis to ensure that the minimum time step cannot drop below $TSSFAC \times DT2MS$. Added mass may increase with time, but it will never decrease.</p> <p>EQ.1: Added mass is calculated at the first time step and remains unchanged thereafter. The initial time step will not be less than $TSSFAC \times DT2MS$, but the time step may subsequently decrease, depending on how the mesh deforms and the element characteristic lengths change.</p> |
| DT2MSF | <p>Reduction (or scale) factor for initial time step size to determine the minimum time step size permitted. Mass scaling is done if it is necessary to meet the Courant time step size criterion. If this option is used, DT2MS effectively becomes $-DT2MSF$ multiplied by the initial time step size, Δt, before Δt is scaled by TSSFAC. This option is active if and only if $DT2MS = 0$ above.</p> |
| DT2MSLC | <p>Load curve for determining the magnitude of DT2MS as a function of time, $f_{DT2MS}(t)$, during the explicit solutions phase. Time zero must be in the abscissa range of this curve and the ordinate values should all be positive. At a given simulation time t, $f_{DT2MS}(t) \times \text{sign}(DT2MS)$ plays the role of DT2MS according to the description for DT2MS above. It is allowed to use all negative ordinate values in the curve, then $f_{DT2MS}(t)$ itself (sign and magnitude) determines how mass scaling is performed and DT2MS is neglected. It is however <i>not</i> allowed for the ordinate values to change sign during the simulation.</p> |
| IMSCL | <p>Flag for selective mass scaling if and only if mass scaling active. Selective mass scaling does not scale the rigid body mass and is therefore more accurate. Since it is memory and CPU intensive, it should be applied only to small finely meshed parts.</p> <p>EQ.0: no selective mass scaling.</p> <p>EQ.1: all parts undergo selective mass scaling.</p> <p>LT.0: recommended; $IMSCL$ is the part set ID of the parts that</p> |

| VARIABLE | DESCRIPTION |
|----------|--|
| RMSCL | <p>undergo selective mass scaling. All other parts are mass scaled the usual way.</p> <p>Flag for using rotational option in selective mass scaling</p> <p>EQ.0.: Only translational inertia are selectively mass scaled</p> <p>NE.0.: Both translational and rotational inertia are selectively mass scaled</p> |

Remarks:

During the solution we loop through the elements and determine a new time step size by taking the minimum value over all elements.

$$\Delta t^{n+1} = \text{TSSFAC} \times \min\{\Delta t_1, \Delta t_2, \dots, \Delta t_N\}$$

where N is the number of elements. The time step size roughly corresponds to the transient time of an acoustic wave through an element using the shortest characteristic distance. For stability reasons the scale factor TSSFAC is typically set to a value of 0.90 (default) or some smaller value. To decrease solution time we desire to use the largest possible stable time step size. Values larger than .90 will often lead to instabilities. Some comments follow:

1. **Sound Speed and Element Size.** The sound speed in steel and aluminum is approximately 5 mm per microsecond; therefore, if a steel structure is modeled with element sizes of 5 mm, the computed time step size would be 1 microsecond. Elements made from materials with lower sound speeds, such as foams, will give larger time step sizes. Avoid excessively small elements and be aware of the effect of rotational inertia on the time step size in the Belytschko beam element. Sound speeds differ for each material, for example, consider:

| | |
|------------|---------|
| Air | 331 m/s |
| Water | 1478 |
| Steel | 5240 |
| Titanium | 5220 |
| Plexiglass | 2598 |

2. **Use Rigid Bodies when Possible.** It is recommended that stiff components be modeled by using rigid bodies. Do not scale the Young's modulus, as that can substantially reduce the time step size.
3. **Triangular Elements.** The altitude of the triangular element should be used to compute the time step size. Using the shortest side is okay only if the calculation is closely examined for possible instabilities. This is controlled by parameter ISDO.

4. **Selective Mass Scaling.** In the explicit time integration context and in contrast to conventional mass scaling, selective mass scaling (SMS) is a well thought out scheme that not only reduces the number of simulation cycles but that also does not significantly affect the dynamic response of the system under consideration. The drawback is that a linear system of equations must be solved in each time step for the accelerations. In this implementation a preconditioned conjugate gradient method (PCG) is used.

An unfortunate consequence of this choice of solver is that the efficiency will worsen when attempting large time steps since the condition number of the assembled mass matrix increases with the added mass. Therefore, caution should be taken when choosing the desired time step size. For large models it is also recommended to only use SMS on critical parts since it is otherwise likely to slow down execution; the bottleneck being the solution step for the system of linear system of equations.

While some constraints and boundary conditions available in LS-DYNA are not supported for SMS, they can be implemented upon request from a user.

A partial list of constraints and boundary conditions supported with SMS:

- Pointwise nodal constraints in global and local directions

- Prescribed motion in global and local directions

- Adaptivity

- Rigid walls

- Deformable elements merged with rigid bodies

- Constraint contacts and spotwelds

- Beam release constraints

By default, only the translational dynamic properties are treated. This means that only rigid body translation will be unaffected by the mass scaling imposed. There is an option to also properly treat rigid body rotation in this way, this is invoked by flagging the parameter RMSCL. A penalty in computational expense is incurred, but the results could be improved if rotations are dominating the simulation.

***CONTROL_UNITS**

Purpose: Specify the user units for the current keyword input deck. This does not provide any mechanism for automatic conversion of units of any entry in the keyword input deck. It is intended to be used for several purposes, but currently only for the situation where an external database in another set of units will be loaded and used in the simulation. In this case, *CONTROL_UNITS provides the information necessary to convert the external data into internal units (see *CHEMISTRY_CONTROL for such external databases).

If the needed unit is not one of the predefined ones listed for use on the first card, then the second optional card is used to define that unit. Any non-zero scales that are entered on optional Card 2 override what is specified on the first card. These scales are given in terms of the default units on Card 1. For instance, if 3600.0 is given in the second 20 character field on the optional second card (TIME_SCALE), then 'hour' is the time unit (3600 seconds).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|------|------|------|---|---|---|---|
| Variable | LENGTH | TIME | MASS | TEMP | | | | |
| Type | A | A | A | A | | | | |
| Default | m | sec | kg | K | | | | |

User Defined Units Card. Optional card only used when a new unit needs to be defined.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------------|---|------------|---|------------|---|---|---|
| Variable | LENGTH_SCALE | | TIME_SCALE | | MASS_SCALE | | | |
| Type | F | | F | | F | | | |
| Default | 1.0 | | 1.0 | | 1.0 | | | |

| VARIABLE | DESCRIPTION |
|------------------|---|
| LENGTH | Length units: EQ.m: meter (default) EQ.mm: millimeter EQ.cm: centimeter EQ.in: inch EQ.ft: foot |
| TIME | Time units: EQ.sec: second (default) EQ.ms: millisecond EQ.micro_s: microsecond |
| MASS | Mass units: EQ.kg: kilogram (default) EQ.g: gram EQ.mg: milligram EQ.lb: pound EQ.slug: pound × second ² / foot EQ.slinch: pound × second ² / inch EQ.mtrc_ton: metric ton |
| TEMP | Temperature units: EQ.K: Kelvin (default) EQ.C: Celsius EQ.F: Fahrenheit EQ.R: Rankine |
| LENGTH_ SCALE | Number of meters in the length unit for the input deck |
| TIME_ SCALE | Number of seconds in the time unit for the input deck |
| MASS_ SCALE | Number of kilograms in the mass unit for the input deck |

***DAMPING**

The keyword options in this section in alphabetical order are:

*DAMPING_FREQUENCY_RANGE

*DAMPING_GLOBAL

*DAMPING_PART_MASS

*DAMPING_PART_STIFFNESS

*DAMPING_RELATIVE

*DAMPING

*DAMPING_FREQUENCY_RANGE

*DAMPING_FREQUENCY_RANGE_{OPTION}

Purpose: This feature provides approximately constant damping (i.e. frequency-independent) over a range of frequencies.

Available OPTIONS are:

<BLANK> Applies damping to global motion

DEFORM Applies damping to element deformation

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|------|-------|------|---|--------|------|---|
| Variable | CDAMP | FLOW | FHIGH | PSID | | PIDREL | IFLG | |
| Type | F | F | F | I | | I | I | |
| Default | 0.0 | 0.0 | 0.0 | 0 | | 0 | 0 | |

VARIABLE

DESCRIPTION

| | |
|--------|--|
| CDAMP | Damping in fraction of critical. |
| FLOW | Lowest frequency in range of interest (cycles per unit time, e.g. Hz if time unit is seconds) |
| FHIGH | Highest frequency in range of interest (cycles per unit time, e.g. Hz if time unit is seconds) |
| PSID | Part set ID. The requested damping is applied only to the parts in the set. If PSID = 0, the damping is applied to all parts except those referred to by other *DAMPING_FREQUENCY_RANGE cards. |
| PIDREL | Optional part ID of rigid body. Damping is then applied to the motion relative to the rigid body motion. This input does not apply to the DEFORM option. |
| IFLG | Method used for internal calculation of damping constants: EQ.0: Iterative (more accurate), EQ.1: Approximate (same as R9 and previous versions). |

Remarks:

This feature provides approximately constant damping (i.e. frequency-independent) over a range of frequencies. $F_{low} < F < F_{high}$. It is intended for small damping ratios (e.g. < 0.05) and frequency ranges such that F_{high}/F_{low} is in the range 10 to 300. The drawback to this method of damping without the DEFORM keyword option is that it reduces the dynamic stiffness of the model, especially at low frequencies.

Where the model contains, for example, a rigid foundation or base, the effects of this stiffness reduction can be ameliorated by using PIDREL. In this case, the damping forces resist motion relative to the base, and are reacted onto the rigid part PIDREL. "Relative motion" here means the difference between the velocity of the node being damped, and the velocity of a point rigidly connected to PIDREL at the same coordinates as the node being damped.

This undesirable effect of *DAMPING_FREQUENCY_RANGE on dynamic stiffness is somewhat predictable. As an example, when the DEFORM keyword option is not used, the natural frequencies of modes close to F_{low} are reduced by 3% for a damping ratio of 0.01 and F_{high}/F_{low} in the range 10-30. Near F_{high} the error is between zero and one third of the error at F_{low} . Estimated frequency errors are shown in the following table. The tabulated values indicate the percent reduction in frequency at FLOW. The error at FHIGH is much less.

| Damping Ratio | % error in frequency for $F_{high}/F_{low} =$ | | |
|---------------|---|-----------|-------------|
| | 3 to 30 | 30 to 300 | 300 to 3000 |
| 0.01 | 3% | 4.5% | 6% |
| 0.02 | 6% | 9% | 12% |
| 0.04 | 12% | 18% | 24% |

It is recommended that the elastic stiffnesses in the model be increased slightly to account for this effect, e.g., for 1% damping across a frequency range of 30 to 600 Hz, the average error across the frequency range is about 2%. It would therefore be appropriate to increase the stiffness by $(1.02)^2$, i.e., by 4%.

Keyword option DEFORM:

The DEFORM option applies damping to the element responses (unlike the standard *DAMPING_FREQUENCY_RANGE which damps the global motion of the nodes). Therefore, rigid body motion is not damped when the DEFORM keyword option is used. For this reason, DEFORM is recommended over the standard option. The damping is adjusted based on current tangent stiffness; this is believed to be more

appropriate for a nonlinear analysis, which could be over-damped if a strain-rate-proportional or viscous damping scheme were used.

The DEFORM keyword option works with the following element formulations:

- Solids – types -1, -2, 1, 2, 3, 4, 9, 10, 13, 15, 16, 17, 99
- Beams – types 1, 2, 3, 4, 5, 9 (note: not type 6)
- Shells – types 1-5, 7-17, 20, 21, 23-27, 99
- Discrete elements

The DEFORM option differs from the standard option in several ways:

Standard Damping vs. Deformation Damping

| Characteristic Property | Keyword Option | |
|------------------------------|---|---|
| | <BLANK> | DEFORM |
| Damping on Rigid body motion | Node velocities Can be damped | Element responses Never damped |
| Natural frequencies | Reduced (by percentages shown in the above table) | Increased (percentages shown in the above table) |
| Recommended compensation | Increase elastic stiffness | Reduce elastic stiffness |
| Effect on time step | None | Small reduction applied automatically, same percentage as in the frequency change |
| Element types damped | All | See list above |
| Damping energy output | Included in "system damping energy" | Included in Internal Energy only if RYLEN = 2 on *CONTROL_ENERGY |

The effect of the DEFORM option on frequency is to increase the frequency, which is opposite the effect when the DEFORM option is not used. Furthermore, when the DEFORM option is invoked, the percent error in frequency shown in first table above occurs at FHIGH and the error at FLOW is much less.

Iterative Method in R10:

Starting with version R10, an iterative method is used by default for the internal calculation of the damping constants (see input variable IFLG). This iterative method is available both with and without the DEFORM keyword option. The iterative method results in the actual damping matching the user-input damping ratio CDAMP more closely across the frequency range FLOW to FHIGH. As an example, for CDAMP = 0.01, FLOW = 1 Hz and FHIGH = 30 Hz, the actual damping achieved by the previous approximate method varied between 0.008 and 0.012 (different values at different frequencies), that is, there were errors of up to 20% of the target CDAMP. With the iterative algorithm, the errors are reduced to 1% of the target CDAMP.

***DAMPING_GLOBAL**

Purpose: Define mass weighted nodal damping that applies globally to the nodes of deformable bodies and to the mass center of the rigid bodies. For specification of mass damping by part ID or part set ID, use *DAMPING_PART_MASS.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|-----|-----|-----|-----|-----|-----|
| Variable | LCID | VALDMP | STX | STY | STZ | SRX | SRY | SRZ |
| Type | I | F | F | F | F | F | F | F |
| Default | 0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 |
| Remarks | 1 | | 2 | 2 | 2 | 2 | 2 | 2 |

VARIABLE**DESCRIPTION**

LCID

Load curve ID (see *DEFINE_CURVE) which specifies the system damping constant vs. time:

EQ.0: a constant damping factor as defined by VALDMP is used,

GT.0: system damping is given by load curve LCID (which must be an integer). The damping force applied to each node is $f = -d(t)mv$, where $d(t)$ is defined by load curve LCID.

VALDMP

System damping constant, D_s (this option is bypassed if the load curve number defined above is non zero).

STX

Scale factor on global x translational damping forces.

STY

Scale factor on global y translational damping forces.

STZ

Scale factor on global z translational damping forces.

SRX

Scale factor on global x rotational damping moments.

SRY

Scale factor on global y rotational damping moments.

SRZ

Scale factor on global z rotational damping moments.

Remarks:

1. **Restart.** This keyword is also used for the restart, see *RESTART.
2. **Defaults for Scale Factors.** If STX = STY = STZ = SRX = SRY = SRZ = 0.0 in the input above, all six values are defaulted to unity.
3. **Damping Exceptions.** Mass damping will not be applied to deformable nodes with prescribed motion or to nodes tied with CONSTRAINED_NODE_SET.
4. **Formulation.** With mass proportional system damping the acceleration is computed as:

$$\mathbf{a}^n = \mathbf{M}^{-1}(\mathbf{P}^n - \mathbf{F}^n - \mathbf{F}_{\text{damp}}^n)$$

where, \mathbf{M} is the diagonal mass matrix, \mathbf{P}^n is the external load vector, \mathbf{F}^n is the internal load vector, and $\mathbf{F}_{\text{damp}}^n$ is the force vector due to system damping. This latter vector is defined as:

$$\mathbf{F}_{\text{damp}}^n = D_s m \mathbf{v}$$

The best damping constant for the system is usually some value approaching the critical damping factor for the lowest frequency mode of interest.

$$(D_s)_{\text{critical}} = 2\omega_{\text{min}}$$

The natural frequency ω_{min} (given in radians per unit time) is generally taken as the fundamental frequency of the structure. This frequency can be determined from an eigenvalue analysis or from an undamped transient analysis. Note that this damping applies to both translational and rotational degrees of freedom. Also note that mass proportional damping will damp rigid body motion as well as vibration.

Energy dissipated by through mass weighted damping is reported as system damping energy in the ASCII file glstat. This energy is computed whenever system damping is active.

*DAMPING

*DAMPING_PART_MASS

*DAMPING_PART_MASS_{OPTION}

OPTION specifies that a part set ID is given with the single option:

<BLANK>

SET

If not used a part ID is assumed.

Purpose: Define mass weighted damping by part ID. Parts may be either rigid or deformable. In rigid bodies the damping forces and moments act at the center of mass. This command may appear multiple times in an input deck but cannot be combined with *DAMPING_GLOBAL.

VARIABLE

DESCRIPTION

PID/PSID

Part ID, see *PART or part set ID, see *SET_PART.

LCID

Load curve ID (see *DEFINE_CURVE) which specifies the damping constant vs. time, applied to the part(s) specified in PID/PSID.

| VARIABLE | DESCRIPTION |
|----------|---|
| SF | Scale factor for load curve. This allows a simple modification of the load curve values. |
| FLAG | Set this flag to unity if the global components of the damping forces require separate scale factors. |
| STX | Scale factor on global x translational damping forces. |
| STY | Scale factor on global y translational damping forces. |
| STZ | Scale factor on global z translational damping forces. |
| SRX | Scale factor on global x rotational damping moments. |
| SRY | Scale factor on global y rotational damping moments. |
| SRZ | Scale factor on global z rotational damping moments. |

Remarks:

Mass weighted damping damps all motions including rigid body motions. For high frequency oscillatory motion stiffness weighted damping may be preferred. With mass proportional system damping the acceleration is computed as:

$$\alpha^n = \mathbf{M}^{-1}(\mathbf{P}^n - \mathbf{F}^n - \mathbf{F}_{\text{damp}}^n)$$

where, \mathbf{M} is the diagonal mass matrix, \mathbf{P}^n is the external load vector, \mathbf{F}^n is the internal load vector, and $\mathbf{F}_{\text{damp}}^n$ is the force vector due to system damping. This latter vector is defined as:

$$\mathbf{F}_{\text{damp}}^n = D_s m \mathbf{v}$$

The critical damping constant for the lowest frequency mode of interest is

$$D_s = 2\omega_{\min}$$

where ω_{\min} is that lowest frequency in units of radians per unit time. The damping constant specified as the ordinate of curve LCID is typically less than the critical damping constant. The damping is applied to both translational and rotational degrees of freedom. The component scale factors can be used to limit which global components see damping forces.

Energy dissipated by through mass weighted damping is reported as system damping energy in the ASCII file glstat. This energy is computed whenever system damping is active.

***DAMPING**

***DAMPING_PART_MASS**

Mass damping will not be applied to deformable nodes with prescribed motion or to nodes tied with `CONSTRAINED_NODE_SET`.

***DAMPING_PART_STIFFNESS_{OPTION}**

OPTION specifies that a part set ID is given with the single option:

<BLANK>

SET

If the SET option is not used, a part ID goes in the first field of Card 1.

Purpose: Assign Rayleigh stiffness damping coefficient by part ID or part set ID. This damping command does not apply to parts comprised of discrete elements (*ELEMENT_DISCRETE) or discrete beams (*ELEMENT_BEAM with ELFORM = 6).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|------|---|---|---|---|---|---|
| Variable | PID/PSID | COEF | | | | | | |
| Type | I | F | | | | | | |
| Default | none | 0.0 | | | | | | |

VARIABLE

DESCRIPTION

PID/PSID

Part ID (see *PART) or part set ID (see *SET_PART).

COEF

Rayleigh damping coefficient. Two methods are now available:

LT.0.0: Rayleigh damping coefficient in units of time, set based on a given frequency and applied uniformly to each element in the specified part or part set. See remarks below.

EQ.0.0: Inactive.

GT.0.0: Rayleigh damping coefficient for stiffness weighted damping. Values between 0.01 and 0.25 are recommended. Higher values are strongly discouraged, and values less than 0.01 may have little effect. The damping coefficient is uniquely defined for each element of the part ID.

Remarks:

The damping matrix in Rayleigh damping is defined as:

$$\mathbf{C} = \alpha\mathbf{M} + \beta\mathbf{K}$$

where \mathbf{C} , \mathbf{M} , and \mathbf{K} are the damping, mass, and stiffness matrices, respectively. The constants α and β are the mass and stiffness proportional damping constants. The mass proportional damping can be treated by system damping, see keywords: *DAMPING_GLOBAL and DAMPING_PART_MASS. Transforming \mathbf{C} with the i^{th} eigenvector ϕ_i gives:

$$\phi_i^T \mathbf{C} \phi_i = \phi_i^T (\alpha\mathbf{M} + \beta\mathbf{K}) \phi_i = \alpha + \beta\omega_i^2 = 2\omega_i\zeta_i\delta_{ij}$$

where ω_i is the i^{th} frequency (radians/unit time) and ζ_i is the corresponding modal damping parameter.

Generally, the stiffness proportional damping is effective for high frequencies and is orthogonal to rigid body motion. Mass proportional damping is more effective for low frequencies and will damp rigid body motion. If a large value of the stiffness based damping coefficient is used, it may be necessary to lower the time step size significantly. This must be done manually by reducing the time step scale factor on the *CONTROL_TIMESTEP control card. Since a good value of β is not easily identified, the coefficient, COEF, is defined such that a value of .10 roughly corresponds to 10% damping in the high frequency domain.

In LS-DYNA versions prior to 960 or if COEF is input as less than 0, the critical damping coefficient is equal to 2 divided by ω_i . For example, 10% of critical damping in the i^{th} mode corresponds to

$$\beta = \frac{0.20}{\omega_i}$$

and COEF would be input as $-\beta$. Typically, this method of applying stiffness damping is stable only if β is significantly smaller than the explicit time step size.

Energy dissipated by Rayleigh damping is computed if and only if the flag, RYLEN, on the control card, *CONTROL_ENERGY is set to 2. This energy is accumulated as element internal energy and is included in the energy balance. In the glstat file this energy will be lumped in with the internal energy.

NOTE: Type 2 beam elements are a special case in which COEF is internally scaled by 0.1. Thus there is a factor of 10 less damping than stated above. This applies to both negative and positive values of COEF.

***DAMPING_RELATIVE**

Purpose: Apply damping relative to the motion of a rigid body. For example, it could damp the deformation of a rotating tire relative to the wheel without damping the rotating motion.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|------|-------|------|-----|------|---|---|
| Variable | CDAMP | FREQ | PIDRB | PSID | DV2 | LCID | | |
| Type | F | F | F | I | F | I | | |
| Default | 0 | 0 | 0 | 0 | 0.0 | 0 | | |

VARIABLE**DESCRIPTION**

| | |
|-------|---|
| CDAMP | Fraction of critical damping. |
| FREQ | Frequency at which CDAMP is to apply (cycles per unit time; for example, Hz if time unit is seconds). |
| PIDRB | Part ID of rigid body; see *PART. Motion relative to this rigid body will be damped. |
| PSID | Part set ID. The requested damping is applied only to the parts in the set. |
| DV2 | Optional constant for velocity-squared term. See Remark 3 . |
| LCID | ID of curve that defines fraction of critical damping as a function of time. CDAMP will be ignored if LCID is non-zero. |

Remarks:

1. **Model Description.** This feature provides damping of vibrations for objects that are moving through space. The vibrations are damped, but not the rigid body motion. This is achieved by calculating the velocity of each node relative to that of a rigid body, and applying a damping force proportional to that velocity. The forces are reacted onto the rigid body such that overall momentum is conserved. It is intended that the rigid body is embedded within the moving object.

2. **Damping.** Vibrations at frequencies below *FREQ* are damped by more than *CDAMP*, while those at frequencies above *FREQ* are damped by less than *CDAMP*. It is recommended that *FREQ* be set to the frequency of the lowest mode of vibration.
3. **Damping Force.** The damping force of each node is calculated as follows:

$$F = - (Dmv) - (DV2 \times mv^2) ,$$

where $D = 4\pi \times CDAMP \times FREQ$, m is the mass of the node, and v is the velocity of the node relative to the velocity of a point on the rigid body at the same coordinates as the node.

*DATABASE

The database definitions are optional, but are necessary to obtain output files containing results information. In this section the database keywords are defined in alphabetical order:

*DATABASE_OPTION
*DATABASE_ALE
*DATABASE_ALE_MAT
*DATABASE_BINARY_OPTION
*DATABASE_CPM_SENSOR
*DATABASE_CROSS_SECTION_OPTION1_{OPTION2}
*DATABASE_EXTENT_OPTION
*DATABASE_FATXML
*DATABASE_FORMAT
*DATABASE_FREQUENCY_ASCII_OPTION
*DATABASE_FREQUENCY_BINARY_OPTION
*DATABASE_FSI
*DATABASE_FSI_SENSOR
*DATABASE_HISTORY_OPTION
*DATABASE_MASSOUT
*DATABASE_NODAL_FORCE_GROUP
*DATABASE_PROFILE
*DATABASE_PAP_OUTPUT
*DATABASE_PWP_FLOW
*DATABASE_PWP_OUTPUT
*DATABASE_RCFORC_MOMENT

***DATABASE**

*DATABASE_SPRING_FORWARD

*DATABASE_SUPERPLASTIC_FORMING

*DATABASE_TRACER

The ordering of the database definition cards in the input file is completely arbitrary.

***DATABASE_OPTION1_{OPTION2}**

OPTION1 specifies the type of database. LS-DYNA will *not* create an ASCII database unless the corresponding *DATABASE_OPTION1 card is included in the input deck. OPTION1 may be any of the items in the following list:

| | |
|-------------------|--|
| ABSTAT | Airbag statistics. |
| ATDOUT | Automatic tiebreak damage statistics for *CONTACT_AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE_TIEBREAK, OPTIONS 7, 9, 10, and 11 (only SMP at the moment). |
| AVSFLT | AVS database. See *DATABASE_EXTENT_OPTION. |
| BEARING | *ELEMENT_BEARING force output. |
| BNDOUT | Boundary condition forces and energy |
| CURVOUT | Output from *DEFINE_CURVE_FUNCTION. |
| DEFGEO | Deformed geometry file. (Note that to output this file in Chrysler format insert the following line in your .cshrc file: "setenv LSTC_DEFGEO chrysler") The nasbdf file (NASTRAN Bulk Data) is created whenever the DEFGEO file is requested. |
| DCFAIL | Failure function data for *MAT_SPOTWELD_DAIMLERCHRYSLER |
| DEFORC | Discrete spring and damper element (*ELEMENT_DISCRETE) data. If the user wishes to be selective about which discrete elements are output in deforc, use *DATABASE_HISTORY_DISCRETE_OPTION to select elements for output (but only if BEAM = 0 in *DATABASE_BINARY_D3PLOT) or set PF = 1 in *ELEMENT_DISCRETE to turn off output for particular elements; otherwise all discrete elements are output. |
| DEMASSFLOW | Measure mass flow rate across defined plane and use together with *DEFINE_DE_MASSFLOW_PLANE. |
| DISBOUT | Discrete beam element, type 6, relative displacements, rotations, and force resultants, all in the local coordinate system, which is also output. Use with *DATABASE_HISTORY_BEAM. |
| ELOUT | Element data. See *DATABASE_HISTORY_OPTION. Also, see Card 3 of the *DATABASE_EXTENT_BINARY parameters INTOUT and NODOUT. This latter option will output all integration point data or extrapolated data to the connectivity nodes in a file call eloutdet. |
| GCEOUT | Geometric contact entities. |
| GLSTAT | Global data. Always obtained if ssstat file is activated. |
| H3OUT | Hybrid III rigid body dummies. |
| JNTFORC | Joint force file |

| | |
|----------------|---|
| MATSUM | Material energies. See Remarks 1 and 2 below. |
| MOVIE | See MOVIE option of *DATABASE_EXTENT_OPTION. |
| MPGS | See MPGS option of *DATABASE_EXTENT_OPTION. |
| NCFORC | Nodal interface forces. See *CONTACT - Card 1 (SPR and MPR) |
| NODFOR | Nodal force groups. See *DATABASE_NODAL_FORCE_GROUP. |
| NODOUT | Nodal point data. See *DATABASE_HISTORY_NODE_OPTION. |
| PBSTAT | Particle blast data. See *PARTICLE_BLAST |
| PLLYOUT | Pulley element data for *ELEMENT_BEAM_PULLEY. |
| PRTUBE | Pressure tube data for *DEFINE_PRESSURE_TUBE. |
| RBDOUT | Rigid body data. See Remark 2 below. |
| RCFORC | Resultant interface forces. Output in a local coordinate system is available, see *CONTACT, Optional Card C. |
| RWFORC | Wall forces. |
| SBTOUT | Seat belt output file |
| SECFORC | Cross section forces. See *DATABASE_CROSS_SECTION_OPTION. |
| SLEOUT | Sliding interface energy. See *CONTROL_ENERGY |
| SPCFORC | SPC reaction forces. |
| SPHOUT | SPH data. See *DATABASE_HISTORY_OPTION. |
| SSSTAT | Subsystem data. See *DATABASE_EXTENT_SSSTAT. |
| SWFORC | Nodal constraint reaction forces (spot welds and rivets). |
| TPRINT | Thermal output from a coupled structural/thermal or thermal only analysis. Includes all nodes unless *DATABASE_HISTORY_NODE_OPTION is also provided in the keyword input. |
| TRHIST | Tracer particle history information. See *DATABASE_TRACER. |

OPTION2, if it set, must be set to FILTER, and this can only be used when OPTION1 is set to NCFORC. When set to FILTER the keyword requires an additional data card, see Card 2 below.

To include global and subsystem mass and inertial properties in the glstat and ssstat files add the keyword option MASS_PROPERTIES as show below. If this option is active the current mass and inertia properties are output including the principle inertias and their axes. Mass of deleted nodes and rigid bodies are not included in the calculated properties.

GLSTAT_MASS_PROPERTIES This is an option for the glstat file to include mass and inertial properties.

SSSTAT_MASS_PROPERTIES This is an option for the ssstat file to include mass and inertial properties for the subsystems.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

| Variable | DT | BINARY | LCUR | IOOPT | OPTION1 | OPTION2 | OPTION3 | OPTION4 |
| Type | F | I | I | I | F/I | I | I | I |
| Default | 0. | 1 or 2 | none | 0. | 0 | 0 | 0 | 0 |

VARIABLE

DESCRIPTION

DT Time interval between outputs. If DT is zero, no output is printed.

BINARY Flag for binary output. See remarks under "Output Files and Post-Processing" in Appendix O, "LS-DYNA MPP User Guide."

EQ.1: ASCII file is written: This is the default for shared memory parallel (SMP) LS-DYNA executables.

EQ.2: Data written to a binary database "binout", which contains data that would otherwise be output to the ASCII file. The ASCII file in this case is not created. This is the default for MPP LS-DYNA executables.

EQ.3: ASCII file is written and the data is also written to the binary database (NOTE: MPP LS-DYNA executables will only produce the binary database).

LCUR Optional curve ID specifying time interval between dumps. Use *DEFINE_CURVE to define the curve; abscissa is time and ordinate is time interval between dumps.

IOOPT Flag to govern behavior of the plot frequency load curve defined by LCUR:

EQ.1: At the time each plot is generated, the load curve value is added to the current time to determine the next plot time.(this is the default behavior)

EQ.2: At the time each plot is generated, the next plot time, t , is

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | computed so that $t = \text{the current time} + \text{LCUR}(t) .$ <p>EQ.3: A plot is generated for each abscissa point in the load curve definition. The actual value of the load curve is ignored.</p> |
| OPTION1 | <p>OPTION1 applies to either the bndout, nodout or elout files. For the nodout file OPTION1 is a <i>real</i> variable that defines the time interval between outputs for the high frequency file, nodouthf. If OPTION1 is zero, no output is printed. Nodal points that are to be output at a higher frequency are flagged using HFO in the DATABASE_HISTORY_NODE_LOCAL input.</p> <p>For the elout file OPTION1 is an <i>integer</i> variable that gives the number of additional history variables written into the elout file for each integration point in the solid elements. See Remark 7 below for the elout file and Remark 9 for the bndout file.</p> |
| OPTION2 | <p>OPTION2 applies to either the bndout, nodouthf or elout files. For the nodouthf OPTION2 defines the binary file flag for the high frequency nodouthf file. See BINARY above.</p> <p>For the elout file OPTION2 is an <i>integer</i> variable that gives the number of additional history variables written into the elout file for each integration point in the shell elements. See Remark 7 below for the elout file and Remark 9 for the bndout file.</p> |
| OPTION3 | <p>OPTION3 applies to the bndout and elout files only. For the elout file OPTION3 is an <i>integer</i> variable that gives the number of additional history variables written into the elout file for each integration point in the thick shell elements. See Remark 7 below for the elout file and Remark 9 for the bndout file.</p> |
| OPTION4 | <p>OPTION4 applies to the bndout and elout files only. For the elout file OPTION4 is an <i>integer</i> variable that gives the number of additional history variables written into the elout file for each integration point in the beam elements. See Remark 7 below for the elout file and Remark 9 for the bndout file.</p> |

The following Card 2 applies only to *DATABASE_NCFORC_FILTER

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|--------|------|---|---|---|---|
| Variable | RATE | CUTOFF | WINDOW | TYPE | | | | |
| Type | F | F | F | I | | | | |
| Default | none | none | none | 0 | 0 | 0 | 0 | 0 |

VARIABLE**DESCRIPTION**

| | |
|--------|---|
| RATE | Time interval T between filter sampling. |
| CUTOFF | Frequency cut-off C in Hz. |
| WINDOW | The width of the window W in units of time for storing the single, forward filtering required for the TYPE = 2 filter option. Increasing the width of the window will increase the memory required for the analysis. A window that is too narrow will reduce the amplitude of the filtered result significantly, and values below 15 are not recommended for that reason. In general, the results for the TYPE = 2 option are sensitive to the width of the window and experimentation is required. |
| TYPE | Flag for filtering options. EQ.0: No filtering (default). EQ.1: Single pass, forward Butterworth filtering. EQ.2: Two pass filtering over the specified time window. Backward Butterworth filtering is applied to the forward Butterworth results that have been stored. This option improves the phase accuracy significantly at the expense of memory. |

† Strains written for solids and for lower and upper integration points of shells and tshells if STRFLG = 1 in *DATABASE_EXTENT_BINARY.

†† “yield function” is whatever is written as the 7th history variable. For example, this would be effective plastic strain for *MAT_024..

| GCEOUT | |
|---------------|----------------|
| x, y, z force | x, y, z moment |

| GLSTAT | |
|-------------------------------------|---|
| time step | total energy |
| kinetic energy | external work |
| internal energy | total and initial energy |
| sprint and damper energy | energy ratio without eroded energy |
| hourglass energy | element & part ID controlling time step |
| system damping energy | global x, y, z velocity |
| sliding interface energy | time per zone cycle |
| eroded kinetic energy [†] | joint internal energy |
| eroded internal energy [†] | stonewall energy |
| eroded hourglass energy | rigid body stopper energy |
| added mass | percentage [mass] increase |

† For implicit, integration errors due to large time steps will result in inaccurate estimates of kinetic and internal energies, regardless of how tight the convergence tolerances are. The “lost” energy arising from this discretization error is accumulated in the eroded kinetic and internal energies, respectively, to render energy balance in the sense described in the introduction. Energy balance in implicit is an implication of having solved the implicit problem to sufficient degree of accuracy, and even though the opposite may not be true it can still be used as an indicator; energy balance *likely* implies a good solution while poor energy balance *definitely* implies a less accurate one.

Remarks:

1. **Discrepancies Between “matsum” and “glstat” Output.** The kinetic energy quantities in the matsum and glstat files may differ slightly in values for several reasons. First, the energy associated with added mass (from mass-scaling) is included in the glstat calculation, but is not included in matsum. Secondly, the energies are computed element by element in matsum for the deformable materials and, consequently, nodes which are merged with rigid bodies will also have their kinetic energy included in the rigid body total. Furthermore, kinetic energy is computed from nodal velocities in glstat and from element midpoint velocities in matsum.
2. **PRINT Keyword Option on *PART.** The PRINT option in the part definition allows some control over the extent of the data that is written into the matsum and rbdout files. If the print option is used the variable PRBF can be defined such that the following numbers take on the meanings:
 - EQ.0: default is taken from the keyword *CONTROL_OUTPUT,
 - EQ.1: write data into rbdout file only,
 - EQ.2: write data into matsum file only,
 - EQ.3: do not write data into rbdout and matsum.

Also see CONTROL_OUTPUT and PART_PRINT.

3. **The Restart Feature.** This keyword is also used in the restart phase, see *RESTART. Thus, the output interval can be changed when restarting.
4. **LS-PrePost.** All information in the files except in AVSFLT, MOVIE, and MPGS can also be plotted using LS-PrePost. Arbitrary cross plotting of results between ASCII files is easily handled.
5. **The “rcforc” File.** Resultant contact forces reported in rcforc are averaged over the preceding output interval.
6. **Spring and Damper Energy.** “Spring and damper energy” reported in glstat is a subset of “Internal energy”. The “Spring and damper energy” includes internal energy of discrete elements, seatbelt elements, and that associated with joint stiffness. (see *CONSTRAINED_JOINT_STIFFNESS...)
7. **OPTION n Field for “elout”.** OPTION1, OPTION2, OPTION3, and OPTION4 give the number of additional history variables output for the integrated solids, shells, thick shells, and beams, respectively. Within this special option, each integration point is printed with its corresponding history data. No integration points are averaged. This is different than the default output where the stress data within a shell ply of a fully integrated shell, for example, are averaged and then written as output. The primary purpose of this database extension is to allow the actual integration point stress data and history variable data to be checked. There are no transformations applied to either the output stresses or history data, e.g., EOCS in *CONTROL_OUTPUT and CMPFLG in *DATABASE_EXTENT_BINARY do not apply to elout when OPTION2 is non-zero.
8. **The Failure Function.** The failure function reported to the DCFAIL database is set to zero when the weld fails. If damage is active, then it is set to the negative of the damage scale factor which goes from 1 to 0 as damage grows.
9. **OPTION n Field for “bndout”.** For the bndout file, OPTION1 controls the nodal force group output, OPTION2 controls the concentrated force output, OPTION3 controls the pressure boundary condition output, and OPTION4 controls the velocity/displacement/acceleration nodal boundary conditions. If the value is 0 or left blank, the category is included (the default), and if it is 1, the category is not included in the bndout file.
10. **Contents of “glstat”.** The glstat table above includes all items that *may* appear in the glstat data. The items that are actually written depend on the contents of the input deck. For example, hourglass energy appears only if HGEN = 2 in *CONTROL_ENERGY and added mass only appears if DT2MS < 0 in *CONTROL_TIMESTEP.

11. **Element ID Controlling the Time Step.** The element ID controlling the time step is included in the `glstat` data but is not read by LS-PrePost. If the element ID is of interest to the user, the ASCII version of the `glstat` file can be opened with a text editor.
12. **The FILTER Option.** The FILTER option uses a Butterworth filter for the forward, single pass filtering and the backward, double pass filtering options. The forward filtered output $Y(n)$ at sampling interval n is obtained from the solution value $X(n)$ using the formula

$$Y(n) = a_0X(n) + a_1X(n-1) + a_2X(n-2) + b_1Y(n-1) + b_2Y(n-2)$$

where the coefficients are

$$\begin{aligned}\omega_d &= 2\pi \left(\frac{C}{0.6} \right) 1.25 \\ \omega_a &= \tan(\omega_d T / 2) \\ a_0 &= \omega_a^2 / (1 + \sqrt{2}\omega_a + \omega_a^2) \\ a_1 &= 2a_0 \\ a_2 &= a_0 \\ b_1 &= 2(1 - \omega_a^2) / (1 + \sqrt{2}\omega_a + \omega_a^2) \\ b_2 &= (-1 + \sqrt{2}\omega_a - \omega_a^2) / (1 + \sqrt{2}\omega_a + \omega_a^2)\end{aligned}$$

The two previous solution values and filtered values at $n-1$ and $n-2$ are stored.

Backward filtering improves the phase response of the filtered output. It is performed according to the formula

$$Z(n) = a_0Y(n) + a_1Y(n+1) + a_2Y(n+2) + b_1Z(n+1) + b_2Z(n+2)$$

where $Z(n)$ is the backward filtered value at sample time n . This implies that all the forward filtered values $Y(n)$ are stored during the analysis, and that would require a prohibitive amount of memory. To limit the amount of memory required, the forward filtered values are stored for the time interval W , where the number of stored states is W/T , and the backward filtering is applied starting at the last saved value of the forward filtered values. As the window width increases, the filtered values approach the values that would be obtained from storing all of the forward filtered values.

The results of the backward filtering are sensitive to the window width, and experimentation with the width is necessary to obtain good results with the minimum window width. A window width of at least 10 to 15 times the sample rate T should be used as a starting point. Some applications may require a window width that is much larger. The required window width decreases as the cut-off frequency increases. Or, to put it another way, the window width must be increased to make the filtered output smoother.

As an example, a random series of numbers between 0 and 1 was generated and filtered at intervals of 0.1 milliseconds with cut-off frequencies from 60 Hz to 420 Hz. The reverse filtering was applied with various window widths to determine how many forward filtered states must be saved to achieve fixed levels of accuracy compared to complete reverse filtering from the last state to the first state. The results are shown in the table below. Note that the error is calculated *only* for the first state and the numbers being filtered are random. *This example should only be used as a very rough guide that indicates the overall trends and not as a recommendation for specific problems.*

| Cut-off Frequency | No. of States 50% Error | No. of States 25% Error | No. of States 10% Error | No. of States 5% Error | No. of States 1% Error |
|-------------------|----------------------------|----------------------------|----------------------------|---------------------------|---------------------------|
| 60 Hz | 26 | 33 | 55 | 68 | 87 |
| 120 Hz | 13 | 16 | 30 | 37 | 44 |
| 180 Hz | 8 | 10 | 22 | 26 | 30 |
| 240 Hz | 6 | 8 | 17 | 19 | 23 |
| 300 Hz | 5 | 6 | 12 | 15 | 18 |
| 360 Hz | 5 | 6 | 10 | 12 | 16 |
| 420 Hz | 4 | 5 | 9 | 10 | 15 |

***DATABASE_ALE**

Purpose: For each ALE group (or material), this card controls the output for element time-history variables (in a tabular format that can be plotted in LS-PrePost by using the XYPlot button).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|---|---|---|---|---|---|
| Variable | DTOUT | SETID | | | | | | |
| Type | F | I | | | | | | |
| Default | none | none | | | | | | |

Variable Cards. Optional cards that can be used to add more variables with the volume fractions in the database (the volume fractions are always output). Include as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-----|-----|-----|-----|
| Variable | VAR |
| Type | I | I | I | I | I | I | I | I |
| Default | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

VARIABLE**DESCRIPTION**

DTOUT

Time interval between the outputs

SETID

ALE element set ID.

If the model is 1D (*SECTION_ALE1D), the set should be *SET_BEAM.

If the model is 2D (*SECTION_ALE2D), the set should be *SET_SHELL.

If the model is 3D (*SECTION_SOLID), the set should be *SET_SOLID.

| VARIABLE | DESCRIPTION |
|----------|---|
| VAR | Variable rank in the following list: EQ.1: <i>xx</i> -stress EQ.2: <i>yy</i> -stress EQ.3: <i>zz</i> -stress EQ.4: <i>xy</i> -stress EQ.5: <i>yz</i> -stress EQ.6: <i>zx</i> -stress EQ.7: plastic strain EQ.8: internal energy EQ.9: bulk viscosity EQ.10: previous volume EQ.11: pressure EQ.12: mass EQ.13: volume EQ.14: density EQ.15: kinetic energy |

If there is a blank column between 2 variable ranks, the list between these 2 ranks is selected. For example, if the card is as follows:

1, , 6

The 6 stresses are added to the database.

Remarks:

1. **Creating .xy Files.** The .xy files are created when the termination time is reached or if one of the following switches (after pressing the keys Ctrl - C) stops the job: sw1, stop, quit. During the run, they can be created with the switch sw2.
2. **Curve Output.** The .xy files are created by element. There is a curve for each ALE group (or material). A curve can be added for volume averaged variables.

***DATABASE_ALE_MAT**

Purpose: For each ALE group (or material), this card activates extra output for:

1. material volume: `alematvol.xy`,
2. material mass: `alematmas.xy`,
3. internal energy: `alematEint.xy`,
4. kinetic energy: `alematEkin.xy`,
5. and kinetic energy loss during the advection: `alematEkinlos.xy`.

These files are written in the “.xy” format, which LS-PrePost can plot with its “XYPlot” button.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|--------|-------|---|---|---|---|---|
| Variable | DTOUT | BOXLOW | BOXUP | | | | | |
| Type | F | I | I | | | | | |
| Default | none | 0 | 0 | | | | | |

VARIABLE**DESCRIPTION**

DTOUT

Time interval between the outputs

BOXLOW, BOXUP

Range of *DEFINE_BOX ids. BOXLOW is the lower bound for the range while BOXUP is the upper bound. The series of volumes covered by the specified range of *DEFINE_BOX determines the mesh regions for which ALE material data are to be output.

Remarks:

The “.xy” files are created at termination or if one of the following switches (Ctrl-C) is encountered: `sw2`, `sw1`, `stop`, `quit`.

***DATABASE_BINARY_OPTION1_OPTION2**

Purpose: This keyword is used to request binary output. See also *DATABASE_EXTENT_BINARY.

Choices for *OPTION1* are:

- BLSTFOR** Blast pressure database. See also *LOAD_BLAST_ENHANCED and [Remark 3](#).
- CPMFOR** Corpuscular Particle Method interface force database. See [Remark 2](#).
- D3DRLF** Dynamic relaxation database.
- D3DUMP** Database for restarts. Define output frequency in cycles.
- D3PART** Database for subset of parts. See also *DATABASE_EXTENT_BINARY and *DATABASE_EXTENT_D3PART.
- D3PLOT** Database for entire model. See also *DATABASE_EXTENT_BINARY.
- D3PROP** Database containing property data. See *DATABASE_BINARY_D3PROP.
- D3THDT** Database containing time histories for subsets of elements and nodes. See *DATABASE_HISTORY. This database does not include geometry.
- DEMFOR** DEM interface force database. See [Remark 5](#).
- FSIFOR** ALE interface force database. The fsifor database does *not* have a default filename, so it *must* be given a filename using "h=" on the execution line. See [Remark 1](#).
- FSILNK** ALE interface linking database. See [Remark 4](#).
- RUNRSF** Database for restarts. Define output frequency in cycles.
- INTFOR** Contact interface database. The intfor database does *not* have a default filename, so it *must* either be given a filename using the FILE option or using "S=" on the execution line. Also see *CONTACT fields SPR and MPR.
- PBMFOR** Particle Blast Method interface force database.
- D3CRACK** Option to control output interval for ASCII "aea_crack" file for the Winfrith concrete model (*MAT_084/085). Oddly, this command does not control the output of the binary crack database for the Winfrith concrete model. The binary crack database is written when "q=" appears on the execution line, and its output interval is taken from *DATABASE_BINARY_D3PLOT. It is used by LS-PrePost to-

gether with the D3PLOT database to display cracks in the deformed Winfrith concrete materials.

The only choice for OPTION2 is "FILE". When OPTION2 is set to "FILE", LS-DYNA requires one extra indicating the filename for the database selected in OPTION1. *Presently, this is only implemented for *DATABASE_BINARY_INTFOR.*

The D3DUMP and the RUNRSF options create complete databases which are necessary for restarts. See *RESTART. When RUNRSF is specified, the same file is overwritten after each interval, unless the field NR is set which causes a series of restart files to be overwritten in a cyclic order. When D3DUMP is specified, a new d3dump file is created after each interval. After the first interval LS-DYNA will write d3dump01, after the second d3dump02 and so on. The default file names are runrsf and d3dump unless other names are specified on the execution line, see the GETTING STARTED, EXECUTION SYNTAX. Since all data held in memory is written into the restart files, these files can be quite large and care should be taken with the d3dump files not to create too many. If *DATABASE_BINARY_D3PLOT is not specified in the keyword deck, then the output interval for d3plot is automatically set to one twentieth of the termination time.

The d3plot, d3part, d3drif, and intfor databases contain histories of geometry and of state variables. With LS-PrePost these databases can be used to, for example, animate deformed geometry and plot time histories of element stresses and nodal displacements. The d3thdt database contains time history data for element subsets and global information, but it does not include information about the geometry. See *DATABASE_HISTORY. This data can be plotted with LS-PrePost. For the contents of the d3plot, d3part and d3thdt databases, see the *DATABASE_EXTENT_BINARY keyword. The size of the databases can be reduced by restricting the information that is dumped. The contents of the d3thdt database are also specified with the *DATABASE_HISTORY definition. Note that in particular the databases can be considerably reduced for models with rigid bodies containing many elements.

The fsifor database, like the intfor database, does not have a default filename. For this database a unique filename must be specified on the execution line with h=filename; see GETTING STARTED, EXECUTION SYNTAX. The file structure is such that each file contains the full geometry at the beginning, followed by the analysis generated output data at the specified time intervals.

FILE Card. When OPTION2 is set to "FILE" read in this additional card. *Presently, this is only implemented for *DATABASE_BINARY_INTFOR.*

| Default | 0 | none | none | none | 0 | 0 | | |

VARIABLE

DESCRIPTION

DT

This field defines the time interval between output states, DT, for all options except D3DUMP, RUNRSF, and D3DRLF.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| CYCL | For D3DUMP and RUNRSF options this field is the number of time steps between output states. For the D3DLF option, the value, n, inputted in this field causes an output state to be written every n'th convergence check during the explicit dynamic relaxation phase. |
| NR | Number of RUNning ReStart Files, runrsf, written in a cyclical fashion. The default is 1, i.e., only one runrsf file is created and the data therein is overwritten each time data is output. |
| LCDT | Optional load curve ID specifying time interval between dumps. This variable is only available for options D3PLOT, D3PART, D3THDT, INTFOR and BLSTFOR. |
| BEAM | Discrete element option flag (*DATABASE_BINARY_D3PLOT only). EQ.0: Discrete spring and damper elements are added to the d3plot database where they are displayed as beam elements. The discrete elements' global x , global y , global z and resultant forces (moments), and change in length (rotation) are written to the database where LS-PrePost (incorrectly) labels them as though they were beam quantities, such as axial force, S-shear resultant, T-shear resultant, etc. EQ.1: No discrete spring, damper and seatbelt elements are added to the d3plot database. This option is useful when translating old LS-DYNA input decks to KEYWORD input. In older input decks there is no requirement that beam and spring elements have unique ID's, and beam elements may be created for the spring and dampers with identical ID's to existing beam elements causing a fatal error. However, this option comes with some limitations and, therefore, should be used with caution. <ol style="list-style-type: none">1. Contact interfaces which are based on part IDs of seatbelt elements will not be properly generated if this option is used.2. DEFORMABLE_TO_RIGID will not work if PID refers to discrete, damper, or seatbelt elements. EQ.2: Discrete spring and damper elements are added to the d3plot database where they are displayed as beam elements (similar to option 0). In this option the element |

| VARIABLE | DESCRIPTION |
|----------|--|
| NPLTC | <p>resultant force is written to its first database position allowing beam axial forces and spring resultant forces to be plotted at the same time. This can be useful during some post-processing applications.</p> <p>This flag, set in *DATABASE_BINARY_D3PLOT, also affects the display of discrete elements in several other databases such as d3drf, d3part.</p> <p>DT = ENDTIM/NPLTC. Applies to D3PLOT and D3PART options only. This overrides the DT specified in the first field. ENDTIM is specified in *CONTROL_TERMINATION.</p> |
| CID | Coordinate system ID for FSIFOR and FSILNK. See *DEFINE_COORDINATE_SYSTEM. |
| PSETID | Part set ID for D3PART and D3PLOT options only. See *SET_PART. Parts in PSETID will excluded in the d3plot database. Only parts in PSETID are included in the d3part database. |
| IOOPT | <p>This variable applies to the D3PLOT option only. Flag to govern behavior of the plot frequency load curve defined by LCDT:</p> <p>EQ.1: At the time each plot is generated, the load curve value is added to the current time to determine the next plot time. This is the default behavior.</p> <p>EQ.2: At the time each plot is generated, the next plot time T is computed so that T equals the current time plus the load curve value at time T.</p> <p>EQ.3: A plot is generated for each abscissa point in the load curve definition. The actual value of the load curve is ignored.</p> |
| RATE | Time interval T between filter sampling. See Remark 7 . |
| CUTOFF | Frequency cut-off C in Hz. See Remark 7 . |
| WINDOW | <p>The width of the window W in units of time for storing the single, forward filtering required for the TYPE = 2 filter option. Increasing the width of the window will increase the memory required for the analysis. A window that is too narrow will reduce the amplitude of the filtered result significantly, and values below 15 are not recommended for that reason. In general, the results for the TYPE = 2 option are sensitive to the width of the window and experimentation is required. See Remark 7.</p> |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| TYPE | Flag for filtering options. See Remark 7 . EQ.0: No filtering (default). EQ.1: Single pass, forward Butterworth filtering. EQ.2: Two pass filtering over the specified time window. Backward Butterworth filtering is applied to the forward Butterworth results that have been stored. This option improves the phase accuracy significantly at the expense of memory. |
| PSET | Part set ID for filtering. If no set is specified, all parts are included. For each element integration point in the d3plot file, 24 words of memory are required in LS-DYNA for the single pass filtering, and more for the two pass filtering. Specifying PSET is recommended to minimize the memory requirements. See Remark 7 . |

Remarks:

1. **FSIFOR.** *DATABASE_BINARY_FSIFOR only applies to models having penalty-based coupling between Lagrangian and ALE materials CTYPE = 4 or 5 in the coupling card, *CONSTRAINED_LAGRANGE_IN_SOLID. When *DATABASE_FSI is defined, a few pieces of coupling information of some Lagrangian surface entities interacting with the ALE materials may be output as history parameters into a file called "dbfsi". Coupling pressure is one of the output variables. However, this coupling pressure is averaged over the whole surface entity being monitored. To obtain coupling pressure contour plot as a function of time over the coupled surface, a user can define the *DATABASE_BINARY_FSIFOR keyword. To use it, three things must be done:
 - a) The INTFORC parameter (*CONSTRAINED_LAGRANGE_IN_SOLID, 4th row, 3rd column) must be turned ON (INTFORC = 1).
 - b) A *DATABASE_BINARY_FSIFOR card is defined controlling the output interval. The time interval between output is defined by the parameter DT in this card.
 - c) This interface force file is activated by executing LS-DYNA as follows:

lsdyna i=**inputfilename.k** ... h=**interfaceforcefilename**

LS-DYNA will then write out the segment coupling pressure and forces to a binary interface force file for contour plotting over the whole simulation interval.

To plot the binary data in this file, type: `lsprepost interfaceforcefilename`.

For example, when all 3 of the above actions are taken, and assuming "h" is set to "fsifor", then a series of "fsifor###" binary files are output for contour plotting. To plot this, type "lsprepost fsifor" (without the double quotes).

- d) Forces from a 2D axisymmetric simulation are reported per radian, regardless of the element formulation used. Multiply the 2D force by 2π to get the 3D force.
2. **CPMFOR.** *DATABASE_BINARY_CPMFOR applies to models using *AIRBAG_PARTICLE feature which controls the output interval of CPM interface force file. This interface force file is activated by executing LS-DYNA with command line option (cpm=).

`lsdyna i=inputfilename.k ... cpm=interfaceforce_filename`

CPM interface force file stores segment's coupling pressure and forces. The coupling pressure is averaged over each segment without considering the effect of ambient pressure, P_{atm} .

3. **BLSTFOR.** The BLSTFOR database is not available for two dimensional axisymmetric analysis.
4. **FSILNK.** The *DATABASE_BINARY_FSILNK variant writes the selected *CONSTRAINED_LAGRANGE_IN_SOLID interface's segment pressure to the fsilnk file for the next analysis without ALE meshes.

`lsdyna i=inputfilename.k ... fsilnk=filename`

5. **DEMFOR.** *DATABASE_BINARY_DEMFOR applies to models using DEM coupling option *DEFINE_DE_TO_SURFACE_COUPLING. This card will control the output interval of DEM interface force file. This interface force file is activated by LS-DYNA command line option (dem=).

`lsdyna i=inputfilename.k ... dem=interfaceforce_filename`

DEM interface force file stores segment's coupling pressure and forces.

6. **PBMFOR.** *DATABASE_BINARY_PBMFOR applies to models using *PARTICLE_BLAST feature which controls the output interval of PBM interface force

file. This interface force file is activated by executing LS-DYNA with command line option (pbm=).

lsdyna i=**inputfilename.k** ... pbm=**interfaceforce_filename**

PBM interface force file stores segment's coupling pressure and forces.

7. **D3PLOT Filtering.** The filtering fields cause the stress data in the d3plot file to be replaced with the filtered stress data.

***DATABASE_BINARY_D3PROP**

Purpose: This card causes LS-DYNA to add the part, material, equation of state, section, and hourglass data to the first d3plot file or else write the data to a separate database d3prop. Rigidwall data can also be included.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|---|---|---|---|---|
| Variable | IFILE | IMATL | IWALL | | | | | |
| Type | I | I | I | | | | | |
| Default | 1 | 0 | 0 | | | | | |

VARIABLE

DESCRIPTION

IFILE

Specify file for d3prop output. (This can also be defined on the command line by adding d3prop = 1 or d3prop = 2 which also sets IMATL = IWALL = 1)

EQ.1: Output data at the end of the first d3plot file.

EQ.2: Output data to the file d3prop.

IMATL

Output *EOS, *HOURLASS, *MAT, *PART and *SECTION data.

EQ.0: No

EQ.1: Yes

IWALL

Output *RIGIDWALL data.

EQ.0: No

EQ.1: Yes

***DATABASE_CPM_SENSOR**

Purpose: This card activates an ASCII file `cpm_sensor`. Its input defines the sensors' locations based on the positions of some Lagrangian segments. The output gives the history of the velocity, temperature, density and pressure averaged on the number of particles contained in the sensors. This card is activated only when the `*AIRBAG_PARTICLE` card is used.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|--------|---|---|---|---|---|---|
| Variable | DT | BINARY | | | | | | |
| Type | F | I | | | | | | |

Sensor Definition Cards. Each card defines one sensor. This card may be repeated to define multiple sensors. Input ends at the next keyword ("`**`") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|--------|----|----|----|---|---|---|
| Variable | SEGID | OFFSET | LX | LY | LZ | | | |
| Type | I | F | F | F | F | | | |

| <u>VARIABLE</u> | <u>DESCRIPTION</u> |
|-----------------|--|
| DT | Output interval |
| BINARY | Flag for the binary file EQ.1: ASCII file is written, EQ.2: Data is written to the binary file <code>binout</code> , EQ.3: ASCII file is written and the data is written to the binary file <code>binout</code> . |
| SEGID | Segment set ID. See <code>*SET_SEGMENT</code> . |
| OFFSET | Offset distance, d , between sensor and the segment center. See Remark 2 . |
| LX | Radius(sphere and cylinder)/length in local x -direction(rectangular) of the sensor. See Remarks 1 and 2 . |

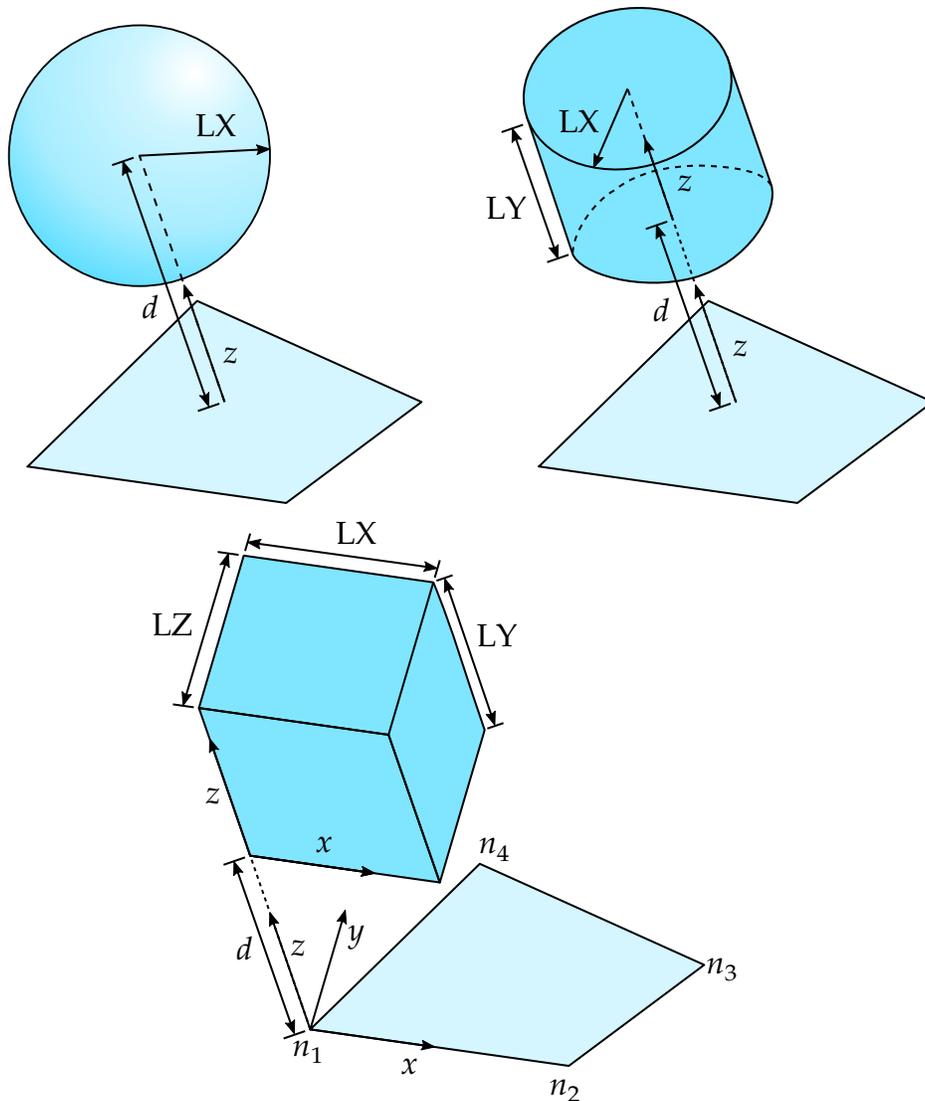

Figure 14-1. Sensor Shapes

| VARIABLE | DESCRIPTION |
|----------|---|
| LY | Length(cylinder)/length in local y -direction(rectangular) of the sensor. See Remarks 1 and 2 . |
| LZ | Length in local z -direction(rectangular) of the sensor. See Remarks 1 and 2 . |

Remarks:

1. **Sensor Shape.** The sensor can be three different shapes, a sphere, cylinder, or rectangle, depending on the length fields defined (LX , LY , and LZ). See [Figure 14-1](#).

- a) If only LX is defined, then the sensor is sphere with radius LX.
 - b) If LX and LY are defined, then the sensor is a cylinder with radius LX and length LY.
 - c) If LX, LY, and LZ are defined, then the sensor is a rectangular prism with side lengths LX, LY, and LZ.
2. **OFFSET.** Each segment has a sensor. The distance between the segment and the sensor is defined by OFFSET (d in [Figure 14-1](#)) in the normal direction of the segment. This distance is constant, that is, the sensor moves along with the segment.
- a) For a spherical sensor, OFFSET is the distance between the sphere center and the segment center. OFFSET should be larger than the radius of the sensor to prevent the segment from cutting the sphere.
 - b) For a cylindrical sensor, OFFSET is the distance from the segment center to the center of the base of the cylinder. The cylinder is extruded in the normal direction of the segment from the base.
 - c) For a rectangular sensor, OFFSET is the distance from the segment to the sensor. The sensor is defined using the segment's coordinate system. The base point for the coordinate system is n_1 from the segment definition (see *SET_SEGMENT). The local x -direction is along the vector $n_2 - n_1$. The local z -direction is the segment normal direction, and the local y -direction is constructed by the cross product of the local z - and x -directions.
3. **Output.** The output parameters in the cpm_sensor file are:
- velx = x -velocity
 - vely = y -velocity
 - velz = z -velocity
 - velr = velocity
 - temp = temperature
 - dens = density
 - pres = pressure

These values are averaged on the number of particles in the sensor. The sensor should be large enough to contain a reasonable number of particles for the averages.

Example:

***DATABASE_CROSS_SECTION_OPTION1_{OPTION2}**

Option 1 includes:

PLANE

SET

To define an ID and heading for the database cross section use the option:

ID

Purpose: Define a cross section for resultant forces written to ASCII file `secforc`.

1. For the PLANE option, a set of two cards is required for each cross section. A cutting plane must be defined, see [Figure 14-2](#). Based on this cutting plane, and the part(s) in a part set PSID, a node set and element set(s) comprising the cross-section are internally generated and output to file(s) named `cross_section_x` where x is the cross-section ID. The purpose of these files is only to provide an easy means to visualize/check the nodes and elements in the cross-section.
2. If the SET option is used, just one card is needed which identifies a node set and at least one element set. In this case the node set(s) defines the cross section, and the forces from the elements belonging to the element set(s) are summed up to calculate the section forces. Thus the element set(s) should include elements on only one side (not both sides) of the cross section.

The cross-section should cut through deformable elements only, not rigid bodies. Cutting through master segments for deformable solid element spot welds can lead to incorrect section forces since the constraint forces are not accounted for in the force and moment summations. Beam element modeling of welds do *not* require any special precautions.

Card Summary:

Card ID. This card is included if and only if the ID keyword option is used.

| | |
|------|---------|
| CSID | HEADING |
|------|---------|

Card 1a.1. This card is included if and only if the PLANE keyword option is used.

| | | | | | | | |
|------|-----|-----|-----|-----|-----|-----|--------|
| PSID | XCT | YCT | ZCT | XCH | YCH | ZCH | RADIUS |
|------|-----|-----|-----|-----|-----|-----|--------|

Card 1a.2. This card is included if and only if the PLANE keyword option is used.

| | | | | | | | |
|------|------|------|------|------|----|-------|--|
| XHEV | YHEV | ZHEV | LENL | LENM | ID | ITYPE | |
|------|------|------|------|------|----|-------|--|

Card 1b. This card is included if and only if the SET keyword option is used.

| | | | | | | | |
|------|------|------|------|------|------|----|-------|
| NSID | HSID | BSID | SSID | TSID | DSID | ID | ITYPE |
|------|------|------|------|------|------|----|-------|

Data Card Definitions:

ID Card. Additional card for ID keyword option. The heading is picked up by some of the peripheral LS-DYNA codes to aid in post-processing.

| | | | | | | | | |
|----------|------|---------|---|---|---|---|---|---|
| Card ID | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | CSID | HEADING | | | | | | |
| Type | I | A70 | | | | | | |

| VARIABLE | DESCRIPTION |
|----------|---|
| CSID | Cross section ID. This must be a unique number. |
| HEADING | Cross section descriptor. It is suggested that unique descriptions be used. |

Plane Card 1. First additional card for PLANE keyword option.

| | | | | | | | | |
|-----------|------|-----|-----|-----|-----|-----|-----|--------|
| Card 1a.1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | PSID | XCT | YCT | ZCT | XCH | YCH | ZCH | RADIUS |
| Type | I | F | F | F | F | F | F | F |
| Default | 0 | 0. | 0. | 0. | 0. | 0. | 0. | 0. |

| VARIABLE | DESCRIPTION |
|----------|---|
| PSID | Part set ID. If zero, all parts are included. |
| XCT | <i>x</i> -coordinate of tail of any outward drawn normal vector, N , originating on wall (tail) and terminating in space (head), see Figure 14-2 . |
| YCT | <i>y</i> -coordinate of tail of normal vector, N . |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| ZCT | z -coordinate of tail of normal vector, N . |
| XCH | x -coordinate of head of normal vector, N . |
| YCH | y -coordinate of head of normal vector, N . |
| ZCH | z -coordinate of head of normal vector, N . |
| RADIUS | Optional radius. If a radius is set (radius $\neq 0.0$), then a circular cut plane will be created that is centered at (XCT,YCT,ZCT) with radius = RADIUS and has a normal vector originating at (XCT,YCT,ZCT) and pointing towards (XCH,YCH,ZCH). In this case the variables XHEV, YHEV, ZHEV, LENL, and LENM, which are defined on the 2 nd card will be ignored. |

Plane Card 2. Second additional card for PLANE keyword option.

| Card 1a.2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-----------|------|------|------|----------|----------|--------|-------|---|
| Variable | XHEV | YHEV | ZHEV | LENL | LENM | ID | ITYPE | |
| Type | F | F | F | F | F | I | I | |
| Default | 0. | 0. | 0. | infinity | infinity | global | 0 | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| XHEV | x -coordinate of head of edge vector, L . |
| YHEV | y -coordinate of head of edge vector, L . |
| ZHEV | z -coordinate of head of edge vector, L . |
| LENL | Length of edge a , in L direction. |
| LENM | Length of edge b , in M direction. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| ID | Rigid body (see *MAT_RIGID, type 20), accelerometer ID (see *ELEMENT_SEATBELT_ACCELEROMETER), or coordinate ID (see *DEFINE_COORDINATE_NODES). The force resultants are output in the <i>updated</i> local system of the rigid body or accelerometer. For ITYPE = 2, the force resultants are output in the updated local coordinate system if FLAG = 1 in *DEFINE_COORDINATE_NODES or if NID is nonzero in *DEFINE_COORDINATE_VECTOR. |
| ITYPE | Flag that specifies whether ID above pertains to a rigid body, an accelerometer, or a coordinate system. EQ.0: rigid body, EQ.1: accelerometer, EQ.2: coordinate system. |

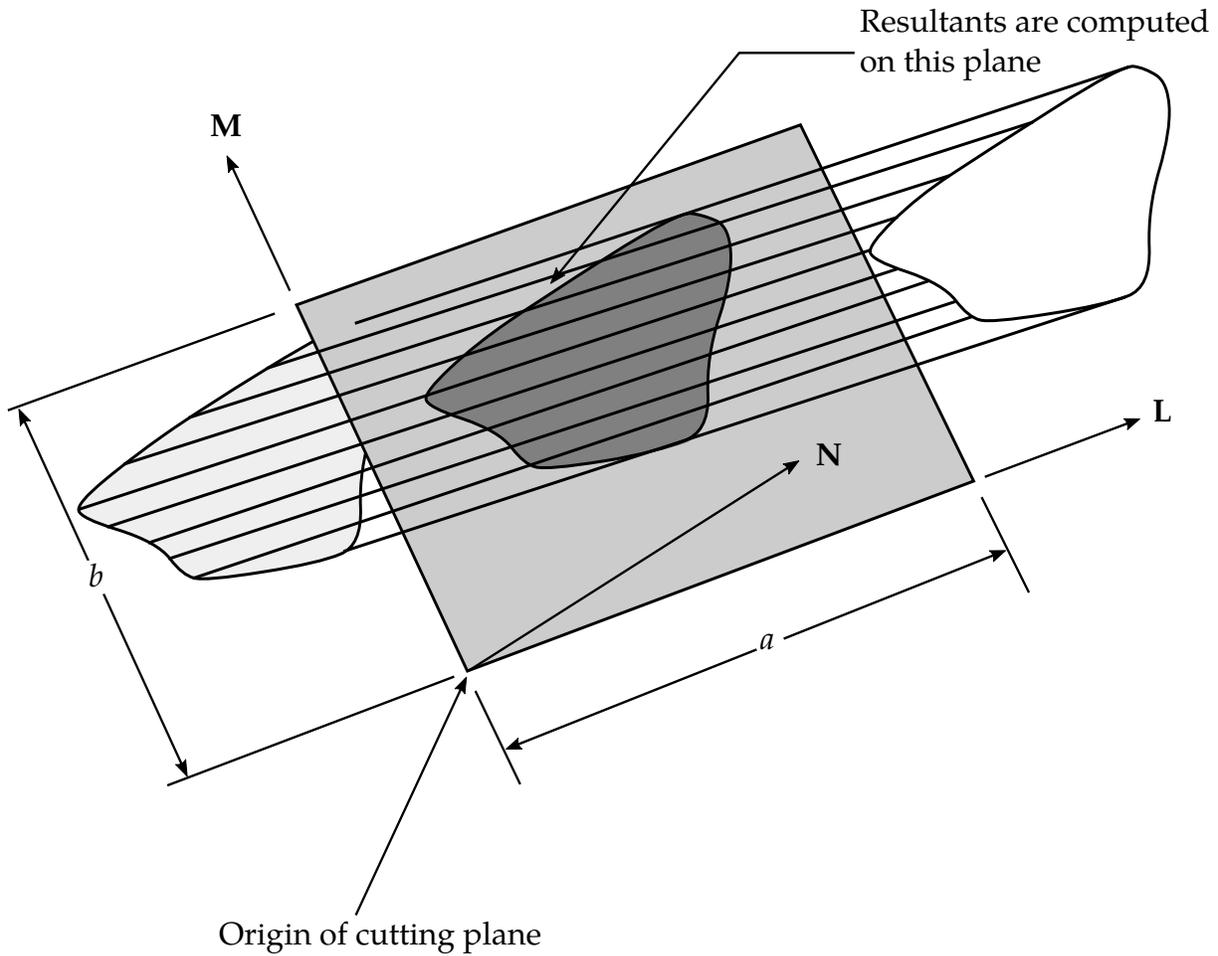

Figure 14-2. Definition of cutting plane for automatic definition of interface for cross-sectional forces. The automatic definition does not check for springs and dampers in the section. For best results the cutting plane should cleanly pass through the middle of the elements, distributing them equally on either side. Elements that intersect the edges of the cutting plane are deleted from the cross-section.

Set Card. Additional Card for the SET keyword option. The set option requires that the equivalent of the automatically generated input by the cutting plane capability be identified manually and defined in sets. All nodes in the cross-section and their related elements that contribute to the cross-sectional force resultants must be defined.

| Card 1b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|------|------|------|------|------|--------|-------|
| Variable | NSID | HSID | BSID | SSID | TSID | DSID | ID | ITYPE |
| Type | I | I | I | I | I | I | I | I |
| Default | required | 0 | 0 | 0 | 0 | 0 | global | 0 |

VARIABLE**DESCRIPTION**

| | |
|-------|--|
| NSID | Nodal set ID, see *SET_NODE_OPTION. |
| HSID | Solid element set ID, see *SET_SOLID. |
| BSID | Beam element set ID, see *SET_BEAM. |
| SSID | Shell element set ID, see *SET_SHELL_OPTION. |
| TSID | Thick shell element set ID, see *SET_TSHELL. |
| DSID | Discrete element set ID, see *SET_DISCRETE. |
| ID | Rigid body (see *MAT_RIGID, type 20), accelerometer ID (see *ELEMENT_SEATBELT_ACCELEROMETER), or coordinate ID (see *DEFINE_COORDINATE_NODES). The force resultants are output in the <i>updated</i> local system of the rigid body or accelerometer. For ITYPE = 2, the force resultants are output in the updated local coordinate system if FLAG = 1 in *DEFINE_COORDINATE_NODES or if NID is nonzero in *DEFINE_COORDINATE_VECTOR. |
| ITYPE | Flag that specifies whether ID above pertains to a rigid body, an accelerometer, or a coordinate system. EQ.0: rigid body, EQ.1: accelerometer, EQ.2: coordinate system. |

***DATABASE_EXTENT_OPTION**

Available options include:

AVS

BINARY

D3PART

INTFOR

MOVIE

MPGS

SSSTAT

Purpose: Control to some extent the content of specific output databases.

The BINARY option of *DATABASE_EXTENT applies to the binary databases d3plot, d3thdt, and d3part. In the case of the d3part database, variables set using the D3PART option will override the corresponding variables of the BINARY option. See also *DATABASE_BINARY_OPTION.

The AVS, MOVIE, and MPGS databases will be familiar to users that have a use for those databases.

***DATABASE_EXTENT_AVS**

Purpose: Control the content written to the avsfll database. See AVSFLT option to *DATABASE card.

Variable Cards. Define as many cards as needed. Input ends at next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|------|---|---|---|---|---|---|
| Variable | VTYPE | COMP | | | | | | |
| Type | I | I | | | | | | |

VARIABLE**DESCRIPTION**

VTYPE

Variable type:

EQ.0: node,

EQ.1: brick,

EQ.2: beam,

EQ.3: shell,

EQ.4: thick shell.

COMP

Component ID. For the corresponding VTYPE, integer components from the following tables can be chosen:

VTYPE.EQ.0: [Table 14-3](#),VTYPE.EQ.1: [Table 14-4](#),

VTYPE.EQ.2: not supported,

VTYPE.EQ.3: [Table 14-5](#),

VTYPE.EQ.4: not supported.

Remarks:

The AVS database consists of a title card, then a control card defining the number of nodes, brick-like elements, beam elements, shell elements, and the number of nodal vectors, NV, written for each output interval. The next NV lines consist of character strings that describe the nodal vectors. Nodal coordinates and element connectivity follow. For each state, the solution time is written, followed by the data requested

below. The last word in the file is the number of states. We recommend creating this file and examining its contents, since the organization is relatively transparent.

Table 14-3. Nodal Quantities

| Component ID | Quantity |
|---------------------|--------------------------|
| 1 | x, y, z -displacements |
| 2 | x, y, z -velocities |
| 3 | x, y, z -accelerations |

| 5 | <i>y</i> -moment resultant |
| 6 | <i>z</i> -moment resultant |

*DATABASE_EXTENT_BINARY_{OPTION}

Purpose: Control to some extent the content of binary output databases d3plot, d3thdt, and d3part. See also *DATABASE_BINARY_OPTION and *DATABASE_EXTENT_D3PART. The content of the binary output database intfor may be modified using *DATABASE_EXTENT_INTFOR.

Available options include:

<BLANK>

COMP

The OPTION COMP controls the content of binary output databases d3plot and d3eigv. When the OPTION COMP is used, it will suppress most of the settings in *DATABASE_EXTENT_BINARY.

Card Summary:

Card 1a. This card is included if and only if the COMP keyword option is used

| VARIABLE | DESCRIPTION |
|----------|--|
| NEIPH | Number of additional integration point history variables written to the binary databases (d3plot, d3part, d3drf) for solid elements and SPH particles. The integration point data is written in the same order that it is stored in memory; each material model has its own history variables that are stored. For user defined materials the history data that is needed for plotting should be stored before the data which is not of interest. See also *DEFINE_MATERIAL_HISTORIES. For output of additional integration point history variables for solid elements to the elout database, see the field OPTION1 for *DATABASE_ELOUT. |
| NEIPS | Number of additional integration point history variables written to the binary databases (d3plot, d3part, d3drf) for both shell and thick shell elements for each integration point; see NEIPH above and *DEFINE_MATERIAL_HISTORIES. For output of additional integration point history variables for shell and thick shell elements to the elout database, see the fields OPTION2 and OPTION3, respectively, in *DATABASE_ELOUT. |

| VARIABLE | DESCRIPTION |
|----------|-------------|
|----------|-------------|

MAXINT Number of shell and thick shell through-thickness integration points for which output is written to d3plot. This does not apply to the strain tensor output flagged by STRFLG.

| MAXINT (def = 3) | Number of Integration Points | Description |
|---------------------|------------------------------------|--|
| 3 | > 3 (even & odd) | results are output for the outermost (top) and innermost (bottom) integration points together with results for the neutral axis. |
| 3 | 1 | All three results are identical. |
| > 3 | ≤ MAXINT | Results for the first MAXINT integration points in the element will be output. |
| ≠ 3 | Even | See above. This will <i>exclude</i> mid-surface results, whereas when MAXINT = 3 mid-surface results are calculated and reported. |
| < 0 | Any | MAXINT integration points are output for each in plane integration point location and no averaging is used. This can greatly increase the size of the binary databases d3plot, d3thdt, and d3part. |

See [Remark 1](#) for more information.

STRFLG STRFLG is interpreted digit-wise STRFLG = [NML],

$$STRFLG = L + M \times 10 + N \times 100$$

L.EQ.1: Write strain tensor data to d3plot and elout. For shell and thick shell elements two tensors are written, one at the innermost and one at the outermost integration point. For solid elements a single strain tensor is written.

M.EQ.1: Write plastic strain data to d3plot.

N.EQ.1: Write thermal strain data to d3plot.

Examples. For STRFLG = 11 (011) LS-DYNA will write both strain

| VARIABLE | DESCRIPTION |
|----------|--|
| | and plastic strain tensors, but no thermal strain tensors. Whereas for STRFLG = 110, LS-DYNA will write plastic and thermal strain tensors but no strain tensors. For more information and supported elements and materials, see Remark 10 . |
| SIGFLG | Flag for including the stress tensor for shells and solids. EQ.1: include (default), EQ.2: exclude for shells, include for solids. EQ.3: exclude for shells and solids. |
| EPSFLG | Flag for including the effective plastic strains for shells and solids: EQ.1: include (default), EQ.2: exclude for shells, include for solids. EQ.3: exclude for shells and solids. |
| RLTFLG | Flag for including stress resultants in the shell LS-DYNA database: EQ.1: include (default), EQ.2: exclude. |
| ENGFLG | Flag for including shell internal energy density and shell thickness: EQ.1: include (default), EQ.2: exclude. |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|--------|-------|------|-------|--------|---------|
| Variable | CMPFLG | IEVERP | BEAMIP | DCOMP | SHGE | STSSZ | N3THDT | IALEMAT |
| Type | I | I | I | I | I | I | I | I |
| Default | 0 | 0 | 0 | 1 | 1 | 1 | 2 | 1 |

| VARIABLE | DESCRIPTION |
|----------|--|
| CMPFLG | Flag to indicate the coordinate system for output of stress and strain of solids, shells and thick shells comprised of orthotropic or anisotropic materials. CMPFLG affects d3plot, eloutdet, and elout, |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | with exceptions as noted below. EQ.-1: Same as 1, but for *MAT_FABRIC (FORM = 14 or -14) and *MAT_FABRIC_MAP the stress and strain is in engineering quantities instead of Green-Lagrange strain and 2nd Piola-Kirchhoff stress. EQ.0: global coordinate system with exception of elout for shells (see EOCS in *CONTROL_OUTPUT). EQ.1: local material coordinate system (as defined by AOPT and associated parameters in the *MAT input, and if applicable, by angles B1, B2, etc. in *SECTION_SHELL, *SECTION_TSHELL, or *PART_COMPOSITE, and by optional input in the *ELEMENT data). CMPFLG = 1 affects both d3plot and elout databases with exception that EOCS = 1 or 2 overrides CMPFLG for shell output in elout. |
| IEVERP | Every output state for the d3plot database is written to a separate file. EQ.0: more than one state can be on each plot file, EQ.1: one state only on each plot file. |
| BEAMIP | Number of beam integration points for output. This option does not apply to beams that use a resultant formulation. See Remark 2 . |
| DCOMP | Data compression to eliminate rigid body data: EQ.1: off (default), no rigid body data compression, EQ.2: on, rigid body data compression active, EQ.3: off, no rigid body data compression, but all nodal velocities and accelerations are eliminated from the database. EQ.4: on, rigid body data compression active and all nodal velocities and accelerations are eliminated from the database. EQ.5: on, rigid body data compression active and rigid nodal data are eliminated from the database. Only 6 DOF rigid body motion is written. EQ.6: on, rigid body data compression active, rigid nodal data, and all nodal velocities and accelerations are eliminated |

| VARIABLE | DESCRIPTION |
|----------|--|
| | from the database. Only 6 DOF rigid body motion is written. |
| SHGE | Flag for including shell hourglass energy density: EQ.1: off (default), no hourglass energy written, EQ.2: on. |
| STSSZ | Flag for including shell element time step, mass, or added mass: EQ.1: off (default), EQ.2: output time step size, EQ.3: output mass, added mass, or time step size. See Remark 3 below. |
| N3THDT | Flag for including material energy in d3thdt database: EQ.1: off, energy is <i>not</i> written to d3thdt database, EQ.2: on (default), energy is written to d3thdt database. |
| IALEMAT | Output solid part ID list containing ALE materials. EQ.1: on (default) |

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---------|---------|------|-------|-------|-------|--------|--------|
| Variable | NINTSLD | PKP_SEN | SCLP | HYDRO | MSSCL | THERM | INTOUT | NODOUT |
| Type | I | I | F | I | I | I | A | A |
| Default | 1 | 0 | 1.0 | 0 | 0 | 0 | none | none |

| VARIABLE | DESCRIPTION |
|----------|---|
| NINTSLD | Number of solid element integration points written to the LS-DYNA database. When NINTSLD is set to 1 (default) or to any value other than 8, integration point values are averaged and only those averages are written output. To obtain values for individual integration points, set NINTSLD to 8, even if the multi-integration point solid has fewer than 8 integration points. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| PKP_SEN | <p>Flag to output the peak pressure and surface energy computed by each contact interface into the interface force database. To obtain the surface energy, FRCENG, must be sent to 1 on the control contact card. When PKP_SEN = 1, it is possible to identify the energies generated on the upper and lower shell surfaces, which is important in metal forming applications. This data is mapped after each h-adaptive remeshing.</p> <p>EQ.0: No data is written</p> <p>EQ.1: Output the peak pressures and surface energy by contact interface</p> |
| SCLP | <p>A scaling parameter used in the computation of the peak pressure. This parameter is generally set to unity (the default), but it must be greater than 0.</p> |
| HYDRO | <p>Either 3, 5 or 7 additional history variables useful to shock physics are output as the last history variables to d3plot (does not apply to elout). For HYDRO = 1, the internal energy per reference volume, the reference volume, and the pressure from bulk viscosity are added to the database; for HYDRO = 2, the relative volume and current density are also added; and for HYDRO = 4, volumetric strain (defined as relative volume - 1.0) and hourglass energy per unit initial volume are additionally added. These history variables are not valid for ALE elements.</p> |
| MSSCL | <p>Output nodal information related to mass scaling into the d3plot database. This option can be activated if and only if DT2MS < 0.0. See control keyword *CONTROL_TIMESTEP.</p> <p>EQ.0: No data is written</p> <p>EQ.1: Output incremental nodal mass</p> <p>EQ.2: Output percentage increase in nodal mass</p> <p>See Remark 3.</p> |
| THERM | <p>Output of thermal data to d3plot. The use of this option (THERM > 0) may make the database incompatible with other 3rd party software.</p> <p>EQ.0: (default) output temperature</p> <p>EQ.1: output temperature</p> <p>EQ.2: output temperature and flux</p> |

| VARIABLE | DESCRIPTION |
|----------|--|
| | EQ.3: output temperature, flux, and shell bottom and top surface temperature |
| INTOUT | <p>Output stress/strain at all integration points for detailed element output in the ASCII file eloutdet. DT and BINARY of *DATABASE_ELOUT apply to eloutdet. See Remark 4.</p> <p>EQ.STRESS: when stress output is required</p> <p>EQ.STRAIN: when strain output is required</p> <p>EQ.ALL: when both stress and strain output are required</p> |
| NODOUT | <p>Output extrapolated stress/strain at connectivity nodes for detailed element output in the ASCII file eloutdet. DT and BINARY of *DATABASE_ELOUT apply to eloutdet. See Remark 4.</p> <p>EQ.STRESS: when stress output is required</p> <p>EQ.STRAIN: when strain output is required</p> <p>EQ.ALL: when both stress and strain output are required</p> <p>EQ.STRESS_GL: when nodal averaged stress output along the global coordinate system is required</p> <p>EQ.STRAIN_GL: when nodal averaged strain output along the global coordinate system is required</p> <p>EQ.ALL_GL: for global nodal averaged stress and strain output</p> |

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|-------|---------|--------|---|---|---|
| Variable | DTDT | RESPLT | NEIPB | QUADSLD | CUBSLD | | | |
| Type | I | I | I | I | I | | | |
| Default | 1 | 0 | 0 | 0 | 0 | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| DTDT | Output of node point Δ temperature/ Δ time data to d3plot. EQ.0: (default) no output EQ.1: output $\Delta T/\Delta t$ |
| RESPLT | Output of translational and rotational residual forces to d3plot and d3iter. EQ.0: No output EQ.1: Output residual |
| NEIPB | Number of additional element or integration point history variables written to the binary databases (d3plot, d3part, d3drf) for beam elements; see NEIPH above, BEAMIP and *DEFINE_MATERIAL_HISTORIES. See also Remark 12 . For output of additional integration point history variables for beam elements to the elout database, see the variable OPTION4 in *DATABASE_ELOUT. |
| QUADSLD | (Under development) Output flag for quadratic solid types 24, 25, and 26: EQ.0: average stress and strain and rendered with 8 nodes EQ.1: average stress and strain and rendered with all edge and face nodes EQ.2: all integration points written and rendered with all edge and face nodes |
| CUBSLD | (Under development) Output flag for cubic solids types 27, 28, and 29: EQ.0: average stress and strain and rendered with 8 nodes EQ.1: average stress and strain and rendered with all edge and face nodes EQ.2: all integration points written and rendered with all edge and face nodes |

Remarks:

1. **MAXINT Field.** If MAXINT is set to 3, then mid-surface, inner-surface and outer-surface stresses are output at the center of the element. For an even number of integration points, the points closest to the center are averaged to

obtain the midsurface values. If multiple integration points are used in the shell plane, the stresses at the center of the element are found by computing the average of these points. For MAXINT equal to 3, LS-DYNA assumes that the data for the user defined integration rules are ordered from bottom to top even if this is not the case. If MAXINT is not equal to 3, then the stresses at the center of the element are output in the order that they are stored for the selected integration rule. If multiple points are used in plane, the stresses are first averaged.

2. **BEAMIP Field.** Beam stresses are output if and only if BEAMIP is greater than zero. In this latter case the data that is output is written in the same order that the integration points are defined. The data at each integration point consists of the following five values for elastic-plastic Hughes-Liu beams: the normal stress, σ_{rr} ; the transverse shear stresses, σ_{rs} and σ_{tr} ; the effective plastic strain; and the axial strain which is logarithmic. For beams that are not elastic-plastic, the first history variable, if any, is output instead of the plastic strain. For the beam elements of Belytschko and his co-workers, the transverse shear stress components are not used in the formulation. No data is output for the Belytschko-Schwer resultant beam.
3. **Mass Scaling.** If mass scaling is active, the output of the time step size reveals little information about the calculation. If global mass scaling is used for a constant time step, the total element mass is output; however, if the mass is increased so that a minimum time step size is maintained (DT2MS is negative), the added mass is output. Also, see the control card *CONTROL_TIMESTEP.
4. **Estimated Stress and Strain Output to eloutdet for Nodes.**
 - a) When NODOUT is set to STRESS, STRAIN , or ALL. Each node of the element nodal connectivity will be output. See [Example 1](#).
 - b) When NODOUT is set to STRESS_GL, STRAIN_GL, or ALL_GL. Averaged nodal results are calculated by summing up all contributions from elements sharing the common node, and then dividing the total by the number of contributing elements. Averaged nodal values are always output in the global coordinate system. See [Example 2](#).
5. **Contents of eloutdet.** Available stress/strain components in eloutdet stress components includes 6 stress components (sig-xx, sig-yy, sig-zz, sig-xy, sig-yz, sig-zx), yielding status, and effective plastic strain. Strain components includes 6 strain components.
6. **Shell Element Output at Integration Points.** Stresses at all integration points can be output. The strain at the top and bottom integration layer can be output. At a connective node the extrapolated stress and strain at the top and bottom layer can be output.

7. **Thick Shells.** Thick shell element output includes the six stress components at each integration point. Strain at the top and bottom layer can be output. At the element node, values at the bottom layer are extrapolated to yield the values of nodes 1 - 4, and values at the top layer are extrapolated to yield values of nodes 5 - 8.
8. **Integration Point Locations.** Stresses and strain at all integration points can be output. The integration point order is as follows:
 - a) point #1 is the point closest to node #1 in the connectivity array
 - b) point #2 is the closest point to node #2, etc
 - c) For tetrahedral types 4, 16 and 17 with 5 integration points, point #5 is the midpoint.
 - d) For the nodal points, values at the integration points are extrapolated.
9. **Reporting Residual Forces and Moments.** The output of residual forces and moments is supported for implicit and double precision only. With this option the forces and moments appear under the *Ndv* button in the fringe menu in LS-PrePost. The residual for rigid bodies is distributed to the slave nodes for the body without scaling for the purpose of capturing the complete residual vector.
10. **Calculation of Strains (STRFLG).** The strain tensors ϵ that are output to the d3plot database are calculated using proper time integration of the rate-of-deformation tensor \mathbf{D} . More specifically, to assert objectivity of the resulting strain, it is for solids using a Jaumann rate of strain whereas for shells it uses the co-rotational strain rate. In mathematical terms the integration is using the following strain rates

$$\dot{\epsilon} = \mathbf{D} - \epsilon \mathbf{W} + \mathbf{W} \epsilon \quad (\text{solids})$$

$$\dot{\epsilon} = \mathbf{D} - \epsilon \mathbf{\Omega} + \mathbf{\Omega} \epsilon \quad (\text{shells})$$

where \mathbf{W} is the spin tensor and $\mathbf{\Omega} = \dot{\mathbf{Q}}\mathbf{Q}^T$ is the rotational velocity of the co-rotational system \mathbf{Q} used for the shell element in question, taking into account invariant node numbering and such. This is to say that the resulting strains would be equal to the Cauchy stress for a hypo-elastic material (MAT_ELASTIC) with a Young's modulus of 1 and a Poisson's ratio of 0. This should be kept in mind when interpreting the results since they are not invariant to changes in element formulations and possibly nodal connectivities.

11. **Plastic and Thermal Strain (STRFLG).** The algorithm for writing plastic and thermal strains, which is also activated using STRFLG, is a modification of the algorithm used for mechanical strains (see [Remark 10](#)).

- a) For solids the element average strain in the global system having 6 components is written (local system if CMPFLG is set).
- b) For shells both plastic and thermal strains have 6 components. The thermal strain is written as a single tensor as in the solid case. The plastic strain output consists of 3 plane-averaged tensors: one for the bottom, one for the middle, and one for the top. For an even number of through thickness integration points, the middle is taken to be the average of the two integration points closest to the mid surface. Currently, only the following element/materials combinations are supported but others *will* be added upon request.

| Thermal strain tensors | | | Plastic strain tensors | | |
|------------------------|--------|----------------------------|------------------------|--------|-----------|
| Shells | Solids | Materials | Shells | Solids | Materials |
| 2, 16, 23 | 1, 2 | Add thermal expansion, 255 | 2, 16, 23 | 1, 2 | 24, 255 |

12. **History Variables for Beams (NEIPB).** In general, NEIPB follows the same conventions as NEIPH and NEIPS do for solid and shell elements and is supported in LS-PrePost v4.3 or later. Average, min and max values for each element are output, including data for resultant elements. If BEAMIP is nonzero, then element data is complemented with BEAMIP integration point values that can be examined individually. Beam history data is post-processed similarly to that of solid and shell element history data.

Example 1:

Excerpt from eloutdet file for a shell element with two through-thickness integration points and four in-plane integration points, with INTOUT = STRESS and NO-DOUT = STRESS:

```

***DATABASE_EXTENT_D3PART**

The following cards control content to the d3part binary database (Card 3 is optional). The parameters given here will supercede the corresponding parameters in *DATABASE_EXTENT_BINARY when writing the d3part binary database. See also *DATABASE_BINARY_D3PART which defines the output interval for d3part and the set of parts included in d3part.

VARIABLE

DESCRIPTION

NEIPH

Number of additional integration point history variables written to the binary database for solid elements. The integration point data is written in the same order that it is stored in memory; each material model has its own history variables that are stored. For

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | user defined materials the history data that is important for plotting should be stored before the data that is not of interest. |
| NEIPS | Number of additional integration point history variables written to the binary database for both shell and thick shell elements for each integration point; see NEIPH above. |
| MAXINT | Number of shell integration points written to the binary database; see also *INTEGRATION_SHELL. See Remark 1 . |
| STRFLG | Set to 1 to dump strain tensors for solid, shell and thick shell elements for plotting by LS-PrePost and ASCII file elout. For shell and thick shell elements two tensors are written, one at the innermost and one at the outermost integration point. For solid elements a single strain tensor is written. |
| SIGFLG | Flag for including the stress tensor for shells: EQ.1: include (default), EQ.2: exclude. |
| EPSFLG | Flag for including the effective plastic strains for shells: EQ.1: include (default), EQ.2: exclude. |
| RLTFLG | Flag for including stress resultants for shells: EQ.1: include (default), EQ.2: exclude. |
| ENGFLG | Flag for including shell internal energy density and shell thickness: EQ.1: include (default), EQ.2: exclude. |
| IEVERP | Every plot state for the d3part database is written to a separate file. This option will limit the database to 1000 states: EQ.0: more than one state can be on each plot file, EQ.1: one state only on each plot file. |

| VARIABLE | DESCRIPTION |
|----------|--|
| SHGE | Flag for including shell hourglass energy density: EQ.1: off (default), no hourglass energy written, EQ.2: on. |
| STSSZ | Flag for including shell element time step, mass, or added mass: EQ.1: off (default), EQ.2: output time step size, EQ.3: output mass, added mass, or time step size. See Remark 2 below. |
| NINTSLD | Number of solid element integration points written. The default value is 1. For solids with multiple integration points NINTSLD may be set to 8. Currently, no other values for NINTSLD are allowed. For solids with multiple integration points, an average value is output if NINTSLD is set to 1. |

Remarks:

1. **MAXINT.** If the default value of 3 is used, then results are output for the outermost (top) and innermost (bottom) integration points together with results for the neutral axis. If MAXINT is set to 3 and the element has 1 integration point, then all three results will be the same. If a value other than 3 is used, then results for the first MAXINT integration points in the element will be output. Note that if the element has an even number of integration points and MAXINT is not set to 3, then you will not get mid-surface results. If MAXINT is set to a negative number, MAXINT integration points are output for each in-plane integration point location and no averaging is used. This can greatly increase the size of the binary d3part database.
2. **Mass Scaling.** If mass scaling is active, the output of the time step size reveals little information about the calculation. If global mass scaling is used for a constant time step, the total element mass is output; however, if the mass is increased so that a minimum time step size is maintained (DT2MS is negative), the added mass is output. Also, see the control card *CONTROL_TIMESTEP.

***DATABASE_EXTENT_INTFOR**

Purpose: The following card controls to some extent the content of the optional intfor binary database. See also *DATABASE_BINARY_INTFOR. The intfor database contains geometry and time history data pertaining to those contact surfaces which are flagged in *CONTACT with the variables SPR and/or MPR. The name of the intfor database must be given on the execution line using "s=filename".

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|--------|--------|-------|-------|-------|--------|
| Variable | NGLBV | NVELO | NPRESU | NSHEAR | NFORC | NGAPC | NFAIL | IEVERF |
| Type | I | I | I | I | I | I | I | I |
| Default | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 |

Optional Card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|------|-------|---|---|---|---|
| Variable | NWEAR | NWUSR | NHUF | NTIED | | | | |
| Type | I | I | I | I | | | | |
| Default | 0 | 0 | 0 | 0 | | | | |

VARIABLE**DESCRIPTION**

| | |
|-------|--|
| NGLBV | Output global variables: EQ.-1: no, EQ.1: yes (default). |
| NVELO | Output nodal velocity: EQ.-1: no, EQ.1: yes (default). |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| NPRESU | Output pressures: EQ.-1: no, EQ.1: normal interface pressure (default), EQ.2: normal interface pressure and peak pressure, EQ.3: normal interface pressure, peak pressure and time to peak. |
| NSHEAR | Output shear stresses: EQ.-1: no, EQ.1: shear stress in <i>r</i> -direction and <i>s</i> -direction (default). |
| NFORC | Output forces: EQ.-1: no, EQ.1: <i>x</i> -, <i>y</i> -, <i>z</i> -force at all nodes (default). |
| NGAPC | Output contact gaps at all nodes and surface energy density. For Mortar contact, see Remark 1 . EQ.-1: no, EQ.1: yes (default). |
| NFAIL | Flag for display of deleted contact segments: EQ.0: all segments are displayed (default), EQ.1: remove deleted contact segments from display. |
| IEVERF | Every interface force state for the “intfor” database is written to a separate file: EQ.0: more than one interface force state can be on each intfor file (default), EQ.1: one interface force output state only on each intfor file. |
| NWEAR | Output contact wear data; see *CONTACT_ADD_WEAR EQ.0: No output (default). GE.1: Output wear depth. GE.2: Output sliding distance. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| NWUSR | Number of user wear history variables to output from user defined wear routines; see *CONTACT_ADD_WEAR. See Remark 2 . |
| NHUF | Number of user friction history variables to output from user defined friction routines; see *USER_INTERFACE_FRICTION (MPP only). See Remark 2 . |
| NTIED | Output tied segments for Mortar contact. See Remark 3 . EQ.0: No output EQ.1: Output |

Remarks:

1. **Gaps in Mortar Contact.** Gaps in Mortar contact are measured with respect to the *nominal* contact surfaces of the two interacting segments. For instance, if IGNORE = 2 on *CONTACT_...MORTAR, then an initial penetration d will dislocate the slave contact surface in the negative direction of the slave surface normal \mathbf{n} . If NGAPC = 1, the gap g reported to the intfor file is still measured between the master and slave surface, neglecting this dislocation; thus only *physical* gaps are reported.
2. **Wear Outputs.** Wear outputs are governed by NWEAR and NWUSR and require the use of a wear model associated with the contact interface. For NWEAR the “wear depth” (NWEAR ≥ 1) and “sliding distance” (NWEAR ≥ 2) are listed under the Nodal fringe menu in LS-PrePost. Following this, NWUSR user defined history variables are listed, corresponding to user wear history variables in a user wear routine. These are listed in the order that they are stored in the wear routine; see WTYPE ≤ 0 on *CONTACT_ADD_WEAR.
3. **Mortar Tied Contacts.** For all Mortar tied contacts, that is,

*CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_MORTAR_TIED,
 *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_MORTAR_TIED_WEL
 D,
 *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_TIEBREAK_MORTAR,

NTIED will activate the output of an indicator stating whether a slave segment is tied (= 1) or not (= 0); nothing is shown on the master side. When opening the intfor file in LS-PrePost, the fringe menu will have two entries saying ‘tied at top’ and ‘tied at bottom’, corresponding to the top and bottom of a shell segment, respectively. The top and bottom labels are with respect to the shell

normal. For obvious reasons, solid segments will only have nonzero values for the 'tied at top' field. For tiebreak contact, these variables represent the relative adhesive strength in the contact, that is, $1 - D$, where D is the damage, so fully damaged segments will show 0 and undamaged segments will show 1. For the tied weld contact the entries will give the segments that have been welded to the corresponding master side of the contact, and can thus have only 0 (not welded) or 1 (welded).

***DATABASE_EXTENT_MOVIE**

Purpose: Control the content written to the MOVIE databases. See movie option on *DATABASE manual entry.

Variable Cards. Define as many cards as needed. Input ends at next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|------|---|---|---|---|---|---|
| Variable | VTYPE | COMP | | | | | | |
| Type | I | I | | | | | | |

VARIABLE**DESCRIPTION**

VTYPE

Variable type:

EQ.0: node,

EQ.1: brick,

EQ.2: beam,

EQ.3: shell,

EQ.4: thick shell.

COMP

Component ID. For the corresponding VTYPE, integer components from the following tables can be chosen:

VTYPE.EQ.0: [Table 14-3](#) (see DATABASE_EXTENT_AVS),

VTYPE.EQ.1: [Table 14-4](#) (see DATABASE_EXTENT_AVS),

VTYPE.EQ.2: not supported,

VTYPE.EQ.3: [Table 14-5](#) (see DATABASE_EXTENT_AVS),

VTYPE.EQ.4: not supported.

***DATABASE_EXTENT_MPGS**

Purpose: Control the content written to the MPGS databases. The created MPGS databases consist of a geometry file and one file for each output database. See MPGS option to *DATABASE keyword.

Variable Cards. Define as many cards as needed. Input ends at the next keyword (“*”) card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|------|---|---|---|---|---|---|
| Variable | VTYPE | COMP | | | | | | |
| Type | I | I | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| VTYPE | Variable type: EQ.0: node, EQ.1: brick, EQ.2: beam, EQ.3: shell, EQ.4: thick shell. |
| COMP | Component ID. For the corresponding VTYPE, integer components from the following tables can be chosen: VTYPE.EQ.0: Table 14-3 (see DATABASE_EXTENT_AVS), VTYPE.EQ.1: Table 14-4 (see DATABASE_EXTENT_AVS), VTYPE.EQ.2: not supported, VTYPE.EQ.3: Table 14-5 (see DATABASE_EXTENT_AVS), VTYPE.EQ.4: not supported. |

***DATABASE_EXTENT_SSSTAT_OPTION**

The only *OPTION* is:

ID

The ID option allows the definition of a heading which will be written at the beginning of the ASCII file *ssstat*.

Purpose: This command defines one or more subsystems. A subsystem is simply a set of parts, grouped for convenience. The ASCII output file *ssstat* provides histories of energy (kinetic, internal, hourglass) and momentum (x , y , and z) for each subsystem. The *ssstat* file is thus similar to *glstat* and *matsum*. But whereas *glstat* provides data for the whole model and *matsum* provides data for each individual part, *ssstat* provides data for each subsystem. The output interval for the *ssstat* file is given using **DATABASE_SSSTAT*. To also include histories of subsystem mass properties in the *ssstat* file, use **DATABASE_SSSTAT_MASS_PROPERTIES*.

For **DATABASE_EXTENT_SSSTAT* without the ID option, the following card(s) applies. Define as many cards as necessary. Define one part set ID per subsystem, up to 8 subsystems per card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|-------|-------|-------|-------|-------|
| Variable | PSID1 | PSID2 | PSID3 | PSID4 | PSID5 | PSID6 | PSID7 | PSID8 |
| Type | I | I | I | I | I | I | I | I |

For **DATABASE_EXTENT_SSSTAT_ID*, the following card(s) applies. Define as many cards as necessary. Define one part set ID per subsystem, 1 subsystem per card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|----------|---|---|---|---|---|---|
| Variable | PSID1 | HEADING1 | | | | | | |
| Type | I | A70 | | | | | | |

VARIABLE**DESCRIPTION**

PSID n

Part set ID for subsystem n ; see **SET_PART*.

| VARIABLE | DESCRIPTION |
|-----------------|-----------------------------|
| HEADING n | Heading for subsystem n . |

***DATABASE_FATXML**

Purpose: Process FATXML data. FATXML is an open, standardized data format based on the Extensible Markup Language (XML) which is developed by the German Research Association of Automotive Technology (Forschungsvereinigung Automobiltechnik - FAT). It is designed for consistent data management in the overall CAE process chain. A comprehensive explanation of the FATXML data format specification is given by Schulte-Frankenfeld and Deiters [2016].

LS-DYNA reads all lines between this keyword and the next keyword recognized by the star (*) sign, processes the data with respect to the include file structure and writes everything together in one output file called 'd3plot.xml'.

Remarks:

It is intended that a corresponding FE model consists of one master file with several associated include files each containing a description by *DATABASE_FATXML data, usually at the end of the file. The master file loads the include files via *INCLUDE_TRANSFORM with potential offset values for nodes, elements, parts, etc. (IDNOFF, IDEOFF, IDPOFF, ...). Finally, all data from different include files with different offsets are collected and then summarized in 'd3plot.xml'. Since the resulting data format is public domain, Post-Processors are able to read that data and correlate it with the associated CAE model.

Example:

```
...
*DATABASE_FATXML
<?xml version="1.0"?>
<CAE_META_DATA>
  < PART_ID NAME="TestCase">
    <PDM_DATA>
      ...
      <PDD_THICKNESS>
        < THICKNESS ID="123">1.0</THICKNESS >
        < THICKNESS ID="124">1.1</THICKNESS >
        ...
      </PDD_THICKNESS >

*DATABASE_FORMAT

Purpose: Define the output format for binary files.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---------|---|---|---|---|---|---|
| Variable | IFORM | IBINARY | | | | | | |
| Type | I | I | | | | | | |
| Default | 0 | 0 | | | | | | |
| Remarks | 1 | 2 | | | | | | |

VARIABLE**DESCRIPTION**

IFORM

Output format for d3plot and d3thdt files

EQ.0: LS-DYNA database format (default),

EQ.1: ANSYS database format,

EQ.2: Both LS-DYNA and ANSYS database formats.

IBINARY

Flag to control the word size in the binary output files, such as d3plot and d3drfl. This variable applies only to double precision LS-DYNA executables.

EQ.0: 64 bit format for binary output (default for double precision),

EQ.1: 32 bit IEEE format for binary output. This reduces the volume of binary output from double precision executables by a factor of two.

Remarks:

1. **MPP and SMP.** The ANSYS output option is not available in MPP and is not universally available in SMP. The LS-DYNA banner in d3hsp will include "ANSYS database format" under the list of "Features enabled" if the option is available.
2. **32 Bit IEEE Format.** As an alternative to setting IBINARY = 1, the user may set the system environment variable LSTC_BINARY to 32ieee.

***DATABASE_FREQUENCY_ASCII_OPTION1_OPTION2**

OPTION1 specifies one of the following frequency domain ASCII databases:

- NODOUT_SSD** ASCII database for nodal results for SSD (displacement, velocity and acceleration). See also *FREQUENCY_DOMAIN_SSD.
- ELOUT_SSD** ASCII database for element results for SSD (stress and strain components). See also *FREQUENCY_DOMAIN_SSD.
- NODFOR_SSD** ASCII database for nodal force group for SSD (nodal forces for each node and reaction forces for the group). See also *FREQUENCY_DOMAIN_SSD.
- NODOUT_PSD** ASCII database for nodal PSD results (displacement, velocity and acceleration). See also *FREQUENCY_DOMAIN_RANDOM_VIBRATION.
- ELOUT_PSD** ASCII database for element PSD results (stress and strain components). See also *FREQUENCY_DOMAIN_RANDOM_VIBRATION.

OPTION2:

MODAL_CONTRIBUTION (see [Remark 10](#))

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-------|--------|--------|---|---|---|
| Variable | FMIN | FMAX | NFREQ | FSPACE | LCFREQ | | | |
| Type | F | F | I | I | I | | | |
| Default | 0.0 | 0.0 | 0 | 0 | 0 | | | |

VARIABLE**DESCRIPTION**

- FMIN Minimum frequency for output (cycles/time)
- FMAX Maximum frequency for output (cycles/time).
- NFREQ Number of frequencies for output.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| FSPACE | Frequency spacing option for output: EQ.0: linear EQ.1: logarithmic EQ.2: biased |
| LCFREQ | Load Curve ID defining the frequencies for output. |

Remarks:

1. The keyword defines output frequencies for NODOUT_SSD / ELOUT_SSD / NODFOR_SSD / NODOUT_PSD / ELOUT_PSD, and they can be different from output frequencies for the binary databases D3SSD / D3PSD (which are defined by the keyword *DATABASE_FREQUENCY_BINARY_D3SSD or *DATABASE_FREQUENCY_BINARY_D3PSD).

2. The ASCII databases NODOUT_SSD / ELOUT_SSD / NODFOR_SSD / NODOUT_PSD / ELOUT_PSD are saved in binout files. LS-PREPOST is able to read the binout files directly. Users can also convert these files to ASCII format simply feed them to the l2a program like this:

l2a binout*

3. The nodes to be output to NODOUT_SSD / NODOUT_PSD are specified by card *DATABASE_HISTORY_NODE.
4. The solid, beam, shell and thick shell elements to be output to ELOUT_SSD / ELOUT_PSD are specified by the following cards:

*DATABASE_HISTORY_SOLID_{OPTION}

*DATABASE_HISTORY_BEAM_{OPTION}

*DATABASE_HISTORY_SHELL_{OPTION}

*DATABASE_HISTORY_TSHELL_{OPTION}

5. The Nodal sets to be output to NODFOR_SSD are specified by card *DATABASE_NODAL_FORCE_GROUP.
6. There are two methods to define the output frequencies.

- a) The first method is to define FMIN, FMAX, NFREQ and FSPACE. FMIN and FMAX specify the frequency range of interest and NFREQ specifies

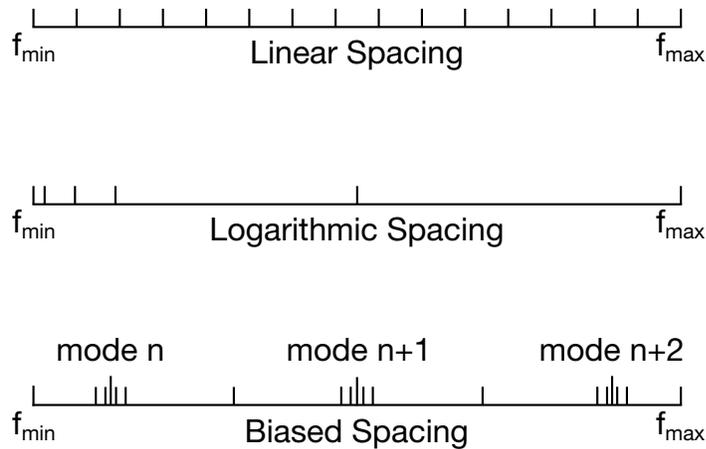

Figure 14-7. Spacing options of the frequency points.

the number of frequencies at which results are required. FSPACE specifies the type of frequency spacing (linear, logarithmic or biased) to be used. These frequency points for which results are required can be spaced equally along the frequency axis (on a linear or logarithmic scale). Or they can be biased toward the eigenfrequencies (the frequency points are placed closer together at eigenfrequencies in the frequency range) so that the detailed definition of the response close to resonance frequencies can be obtained.

- b) The second method is to use a load curve (LCFREQ) to define the frequencies of interest.
7. When OPTION2 MODAL_CONTRIBUTION is present, LS-DYNA computes also the modal contribution fraction for each of the involved vibration modes. The modal contribution fraction shows the percentage of the response contributed by one particular mode, over the total response. The modal contribution fraction values are saved in binout, and can be processed using LS-PrePost. OPTION2 is only valid for SSD computation (e.g. OPTION1 is NODOUT_SSD, or ELOUT_SSD).

***DATABASE_FREQUENCY_BINARY_OPTION**

Options for frequency domain binary output files with the default names given include:

- D3ACC** Binary output file for BEM acoustics (element acoustic pressure contribution and contribution percentage). See also *FREQUENCY_DOMAIN_ACOUSTIC_BEM.
- D3ACS** Binary output file for FEM acoustics (acoustic pressure and sound pressure level in the acoustic volume) and BEM (collocation BEM) acoustics (acoustic pressure, sound pressure level, and normal velocity on the surface of the acoustic volume). See also *FREQUENCY_DOMAIN_ACOUSTIC_FEM, and *FREQUENCY_DOMAIN_ACOUSTIC_BEM.
- D3ATV** Binary output file for acoustic transfer vectors given by BEM acoustic analysis. See also *FREQUENCY_DOMAIN_ACOUSTIC_BEM_ATV.
- D3FTG** Binary output file for random vibration fatigue analysis. See also *FREQUENCY_DOMAIN_RANDOM_VIBRATION_FATIGUE.
- D3PSD** Binary Power Spectral Density output file for random vibration analysis. See also *FREQUENCY_DOMAIN_RANDOM_VIBRATION.
- D3RMS** Binary Root Mean Square output file for random vibration analysis. See also *FREQUENCY_DOMAIN_RANDOM_VIBRATION.
- D3SPCM** Binary output file for response spectrum analysis. See also *FREQUENCY_DOMAIN_RESPONSE_SPECTRUM.
- D3SSD** Binary output file for steady state dynamics. See also *FREQUENCY_DOMAIN_SSD.
- D3ZCF** Binary Zero-Crossing Frequency output file for random vibration analysis. See also *FREQUENCY_DOMAIN_RANDOM_VIBRATION.

The D3ACC, D3ACS, D3ATV, D3FTG, D3PSD, D3RMS, D3SPCM, D3SSD and D3ZCF files contain plotting information to plot data over the three dimensional geometry of the model. These databases can be plotted with LS-PrePost.

- The D3PSD file contains PSD state data for a range of frequencies. The D3SSD file contains state data for a range of frequencies.
- For D3SSD, the data can be real or complex, depending on the variable BINARY defined below.
- The D3ACC file contains acoustic pressure contribution (and contribution percentage) from each of the boundary elements for a range of frequencies, which are defined in the keyword *FREQUENCY_DOMAIN_ACOUSTIC_BEM.

- The D3ACS file contains acoustic results including acoustic pressure and sound pressure level for a range of frequencies, which are defined in the keyword *FREQUENCY_DOMAIN_ACOUSTIC_FEM. Alternatively, it can be used to plot acoustic pressure, sound pressure level and normal velocity on the surface of an acoustic volume for a range of frequencies, which are defined in the keyword *FREQUENCY_DOMAIN_ACOUSTIC_BEM. Please note that only collocation BEM (METHOD = 3 or 4 in *FREQUENCY_DOMAIN_ACOUSTIC_BEM) can output the acoustic pressure, sound pressure level and normal velocity on the surface of the acoustic volume to D3ACS.
- The D3FTG, D3RMS, D3SPCM and D3ZCF files contain only one state each as they are the data for cumulative fatigue damage ratio, root mean square of response for random vibration, peak response for response spectrum analysis and zero-crossing frequency of response for random vibration separately.
- The D3ATV file contains NFIELD × NFREQ states, where NFIELD is the number of acoustic field points and NFREQ is the number of output frequencies.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|---|---|---|---|---|---|---|
| Variable | BINARY | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

D3ACC Card. Additional card for D3ACC keyword options. Include as many of this card as needed. Up to 10 NID are allowed.

| Card 2a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | NID1 | NID2 | NID3 | NID4 | NID5 | NID6 | NID7 | NID8 |
| Type | I | I | I | I | I | I | I | I |
| Default | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

D3PSD and D3SSD Card. Additional card for D3PSD and D3SSD keyword options.

| Card 2b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-------|--------|--------|---|---|---|
| Variable | FMIN | FMAX | NFREQ | FSPACE | LCFREQ | | | |
| Type | F | F | I | I | I | | | |
| Default | 0.0 | 0.0 | 0 | 0 | 0 | | | |

VARIABLE**DESCRIPTION**

| | |
|----------|---|
| BINARY | Flag for writing the binary plot file. See Remark 1 . EQ.0: Off EQ.1: write the binary plot file EQ.2: write the complex variable binary plot file (D3SSD only) EQ.90: write only real part of frequency response (D3SSD only) EQ.91: write only imaginary part of frequency response (D3SSD only) |
| NID1,... | Field point node ID for writing D3ACC file (up to 10 NID are allowed) |
| FMIN | Minimum frequency for output (cycles/time). See Remark 2 . |
| FMAX | Maximum frequency for output (cycles/time). See Remark 2 . |
| NFREQ | Number of frequencies for output. See Remark 2 . |
| FSPACE | Frequency spacing option for output (See Remark 2): EQ.0: linear EQ.1: logarithmic EQ.2: biased |
| LCFREQ | Load Curve ID defining the frequencies for output. See Remark 2 . |

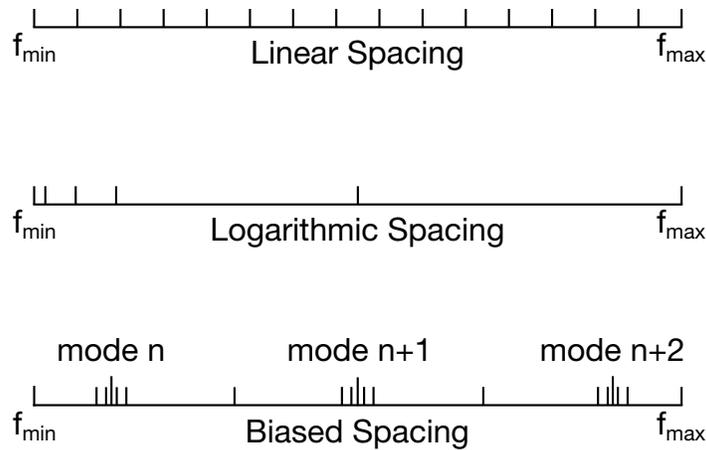

Figure 14-8. Spacing options of the frequency points.

Remarks:

1. **Binary Data Written for D3SSD.** For `OPTION = D3SSD`, If `BINARY = 1`, only the magnitude of the displacement, velocity, acceleration and stress response is written into the binary database “d3ssd” which can be accessed by LS-PrePost 3.0 or older versions. For customers using LS-PrePost 3.0 or older versions, it is suggested to set `BINARY = 1`. If `BINARY = 2`, both the magnitude and the phase angle of the response are written into “d3ssd” so that LS-PrePost (3.1 or higher versions) can run modal expansion (to show the cyclic time history fringe plot) on each output frequency. If `BINARY = 90` or `91`, only real or imaginary part of the response is written into “d3ssd”.
2. **Output Frequencies.** There are two methods to define the output frequencies.
 - a) The first method is to define `FMIN`, `FMAX`, `NFREQ` and `FSPACE`. `FMIN` and `FMAX` specify the frequency range of interest and `NFREQ` specifies the number of frequencies at which results are required. `FSPACE` specifies the type of frequency spacing (linear, logarithmic or biased) to be used. These frequency points for which results are required can be spaced equally along the frequency axis (on a linear or logarithmic scale). Or they can be biased toward the eigenfrequencies (the frequency points are placed closer together at eigenfrequencies in the frequency range) so that the detailed definition of the response close to resonance frequencies can be obtained. See [Figure 14-7](#).
 - b) The second method is to use a load curve (`LCFREQ`) to define the frequencies of interest.

***DATABASE_FSI**

Purpose: When a Lagrangian mesh overlaps with an Eulerian or ALE mesh, the fluid-structure (or ALE-Lagrangian) interaction is often modeled using the *CONSTRAINED_LAGRANGE_IN_SOLID card. This keyword (*DATABASE_FSI) causes certain coupling information related to the flux through and load on selected Lagrangian surfaces defined in corresponding *CONSTRAINED_LAGRANGE_IN_SOLID card to be written to the ASCII-based dbfsi file or in the case of MPP-DYNA the binout file.

NOTE: This card *must* be associated with a *CONSTRAINED_LAGRANGE_IN_SOLID penalty method coupling. This card is *not* compatible with constrained-based coupling.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|---|---|---|---|---|---|
| Variable | DTOUT | | | | | | | |
| Type | F | | | | | | | |

Surface Card. Add one card per surface. This input terminates at the next keyword (“*”) card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|-----|---------|------|--------|---------|-----|---|
| Variable | DBFSI_ID | SID | SIDTYPE | SWID | CONVID | NDSETID | CID | |
| Type | I | I | I | I | I | I | I | |

VARIABLE**DESCRIPTION**

DTOUT

Output interval time step

DBFSI_ID

Surface ID (for reference purposes only) or a DATABASE_FSI entity ID. It consists of a geometric entity defined by the SID below.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| SID | Set ID defining the geometrical surface(s) through which or upon which some data is to be tracked and output to a file called "dbfsi". This set ID can be a (1) PID or (2) PSID or (3) SGSID. This Lagrangian SID must be contained in a Lagrangian slave SID defined in a corresponding coupling card, *CONSTRAINED_LAGRANGE_IN_SOLID. |
| SIDTYPE | Set type: EQ.0: Part set EQ.1: Part EQ.2: Segment set |
| SWID | This is an ID from a corresponding *ALE_FSI_SWITCH_MMG_ID card. This card allows for the AMMG ID of an ALE material to be switched as it passes across a monitoring surface. If defined, the accumulative mass of the "switched" ALE multi-material group (AMMG) is written out under the "mout" parameter in the "dbfsi" file. |
| CONVID | This is used mostly for airbag application only: CONVID is an ID from a corresponding *LOAD_ALE_CONVECTION_ID card which computes the heat transfer between inflator gas (ALE material) and the inflator canister (Lagrangian part). If defined, the temperature of the Lagrangian part having heat transfer with the gas, and its change in temperature as function of time are output in the "dbfsi" file. |
| NDSETID | Set ID consisting of the nodes on which the moments of the forces applied on SID are computed. See Remark 3 . |
| CID | Coordinate system ID, see *DEFINE_COORDINATE_SYSTEM. |

Remarks:

1. **Overview of dbfsi File.** The dbfsi parameters output are enumerated below.

pres = Averaged estimated coupling pressure over each surface entity being monitored. For example, if using SI base units for mass-length-time-temperature, this pressure would then be in Pascal.

fx, fy, fz = Averaged total estimated coupling force components (N in metric units) along the global coordinate directions, over each surface entity defined, and acting at the centroid of each surface.

mout = Accumulated mass (Kg in metric units) passing through each DBFS_ID surface entity. See [Remark 2](#) below. (This parameter used to be called "pleak").

obsolete = (This parameter used to be called "mflux").

gx, gy, gz = Average estimated leakage-control force component over the surface entity. This data is useful for debugging. Leakage control forces are too large (relative to the main coupling forces, fx, fy and fz) may indicate that alternate coupling approach should be considered since the main coupling force is putting out too little resistance to leakage. (These parameters used to be called fx-lc, fy-lc and fz-lc).

Ptmp = Lagrangian part Temperature (Activated only when the *LOAD_ALE_CONVECTION card is used).

PDt = Lagrangian part Temperature change (Activated only when the *LOAD_ALE_CONVECTION card is used).

2. **MOUT.** "mout" parameter in the "dbfsi" output from this keyword contains the accumulated mass passing through each DBFS_ID surface entity. For 4 different cases:
 - a) When LCIDPOR is defined in the coupling card (CLIS), porous accumulated mass transport across a Lagrangian shell surface may be monitored and output in "mout".
 - b) Porous flow across Lagrangian shell may also be defined via a load curve in the *MAT_FABRIC card, and similar result will be tracked and output. This is an alternate form of (a).
 - c) When NVENT in the CLIS card is defined (isentropic venting), the venting mass transport across the isentropic vent hole surface may be output in "mout".
 - d) When an *ALE_FSI_SWITCH_MMG_ID card is defined, and the SWID parameter specifies this ID to be tracked, then the amount of accumulated mass that has been switched when passing across a monitoring surface is output.

3. **Calculation of Moments for NDSETID.** A geometrical surface SID has a centroid where the coupling forces are averaged. The distances between this centroid and the nodes defined by the set NDSETID are the lever arms. The moments are the cross-products of these distances with the averaged coupling forces. For each node in the set NDSETID, a new line in the "dbfsi" file is inserted after each output for the corresponding coupling forces (see Remark 1). These additional lines have the format following the template established by the example in Remark 1 where the forces are replaced by the moments and the node ID replaces the DBFSI_ID values.
4. **2D axisymmetric models.** The forces from a 2D axisymmetric simulation are reported per radian, regardless of the element formulation used. Multiply the 2D force by 2π to get the 3D force.

Example:

Consider a model with a Lagrangian mesh overlaps with an Eulerian or ALE mesh. On the Lagrangian mesh, there are 3 Lagrangian surface sets over which some data is to be written out.

```

$...|...1....|...2....|...3....|...4....|...5....|...6....|...7....|...8
$ INPUT:
$...|...1....|...2....|...3....|...4....|...5....|...6....|...7....|...8
*DATABASE_FSI
$ dt

***DATABASE_FSI_SENSOR**

Purpose: Activate the output of an ASCII file called `dbsensor`. This keyword's input defines the pressure sensors' locations which follow the positions of some Lagrangian segments during the simulation. The ASCII output file, `dbsensor`, contains the spatial position of the sensor and its recorded pressure from the ALE elements containing the sensors. This card is activated when a `*CONSTRAINED_LAGRANGE_IN_SOLID` card is used and the Lagrangian shell elements defining the locations of the sensors must be included in the slave or structure coupling set.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|---|---|---|---|---|---|---|
| Variable | DT | | | | | | | |
| Type | F | | | | | | | |

Surface Card. Add one card per surface. This input terminates at the next keyword ("`*`") card.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|-----|--------|--------|-----|-----|-----|---|
| Variable | DBFSI_ID | NID | SEGMID | OFFSET | ND1 | ND2 | ND3 | |
| Type | I | I | I | F | I | I | I | |

VARIABLE**DESCRIPTION**

| | |
|----------|--|
| DT | Output interval |
| DBFSI_ID | Pressure-Sensor ID. |
| NID | An optional Lagrangian node ID defining an approximate pressure sensor location with respect to a Lagrangian shell element. This is not a required input. |
| SEGMID | A required Lagrangian element ID for locating the pressure sensor. If <code>NID = 0</code> or is blank, the sensor will be automatically placed in the center of this <code>SEGMID</code> , accounting for the offset distance. If the model is three-dimensional, the Lagrangian element can be a shell or solid (for the solid element, <code>ND1</code> and <code>ND2</code> are required to define the face). If the model is two-dimensional, the Lagrangian element can be a beam or shell (for the shell element, <code>ND1</code> and <code>ND2</code> are required to define the side). |

| VARIABLE | DESCRIPTION |
|------------------|---|
| OFFSET | Offset distance between the pressure sensor and the Lagrangian segment surface. If it is positive, it is on the side pointed to by the segment normal vector; otherwise, vice versa. |
| ND1, ND2, ND3 | Nodes defining the solid face for the solid element in the three-dimensional model or shell side for the shell element in the two-dimensional model, from which the sensor is located. In three dimensions, if the solid face has 4 nodes, only the diagonal opposites ND1 and ND2 are required. If the solid face is triangular, a third node ND3 should be provided. In two dimensions, only ND1 and ND2 are required to define the shell side. |

Remarks:

- The output parameters in the `dbsensor` ASCII file are:

ID = Sensor ID.

x, y, z = Sensor spatial location.

P = Sensor recorded pressure (Pa) from the ALE fluid element containing the sensor.

To plot the sensor pressure in LS-PrePost, select:

ASCII → *dbsensor* → *LOAD* → (*select sensor ID*) → *Pressure* → *PLOT*

Example 1:

```

$...|...1...|...2...|...3...|...4...|...5...|...6...|...7...|...8

Purpose: Control which nodes or elements are output into the binary history file d3thdt, the ASCII file nodout, the ASCII file elout and the ASCII file sphout. See also *DATABASE_BINARY and *DATABASE.

Card Summary:

Card 1a. This card is included if and only if the keyword option is BEAM, BEAM_SET, DISCRETE, DISCRETE_SET, NODE, NODE_SET, SEATBELT, SHELL, SHELL_SET, SOLID, SOLID_SET, SPH, SPH_SET, TSHELL, or TSHELL_SET. Include as many as needed. Input terminates at the next keyword ("**") card.

| | | | | | | | |
|-----|-----|-----|-----|-----|-----|-----|-----|
| ID1 | ID2 | ID3 | ID4 | ID5 | ID6 | ID7 | ID8 |
|-----|-----|-----|-----|-----|-----|-----|-----|

Card 1b. This card is included if and only if the keyword option is BEAM_ID, NODE_ID, SEATBELT_ID, SHELL_ID, SOLID_ID, and TSHELL_ID. Include as many as needed. Input terminates at the next keyword ("**") card.

| | |
|----|---------|
| ID | HEADING |
|----|---------|

Card 1c. This card is included if and only if the keyword option is NODE_LOCAL, NODE_LOCAL_ID, and NODE_SET_LOCAL. If the keyword option is NODE_LOCAL_ID, see Card 1c.1 as well. Include as many cards as needed to specify all the nodes. This input terminates at the next keyword ("**") card.

| | | | | | | | |
|----|-----|-----|-----|--|--|--|--|
| ID | CID | REF | HFO | | | | |
|----|-----|-----|-----|--|--|--|--|

Card 1c.1. This card is only used for the NODE_LOCAL_ID keyword option. When activated, each node is specified by a pair of cards consisting of Card 1c, and, secondly, this card. Include as many pairs as needed to specify all the nodes. This input terminates at the next keyword ("**") card.

| | |
|---------|--|
| HEADING | |
|---------|--|

Data Cards:

Node/Element Cards for Case I (no “ID”, and no “LOCAL”). Cards for keyword options BEAM, BEAM_SET, DISCRETE, DISCRETE_SET, NODE, NODE_SET, SEATBELT, SHELL, SHELL_SET, SOLID, SOLID_SET, SPH, SPH_SET, TSHELL, and TSHELL_SET. Include as many as needed. Input terminates at the next keyword (“*”) card.

| | | | | | | | | |
|----------|-----|-----|-----|-----|-----|-----|-----|-----|
| Card 1a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | ID1 | ID2 | ID3 | ID4 | ID5 | ID6 | ID7 | ID8 |
| Type | I | I | I | I | I | I | I | I |

| VARIABLE | DESCRIPTION |
|------------------------|---|
| ID _{<i>n</i>} | NODE / NODE_SET or element / element set ID <i>n</i> . Elements may be BEAM / BEAM_SET, DISCRETE / DISCRETE_SET, SEATBELT, SHELL / SHELL_SET, SOLID / SOLID_SET, or TSHELL / TSHELL_SET. The contents of the files are given in Table 14-3 for nodes, Table 14-4 for solid elements, Table 14-5 for shells and thick shells, and Table 14-6 for beam elements. In the binary file, d3thdt, the contents may be extended or reduced with the *DATABASE_EXTENT_BINARY definition. |

Node/Element Cards for Case II (“ID” option, but no “LOCAL”). Cards for keyword options BEAM_ID, NODE_ID, SEATBELT_ID, SHELL_ID, SOLID_ID, and TSHELL_ID. Include as many as needed. Input terminates at the next keyword (“*”) card.

| | | | | | | | | |
|----------|----|---------|---|---|---|---|---|---|
| Card 1b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | ID | HEADING | | | | | | |
| Type | I | A70 | | | | | | |

| VARIABLE | DESCRIPTION |
|----------|--|
| ID | Node or element ID |
| HEADING | A description of the node or element. It is suggested that unique descriptions be used. This description is written into the d3hsp file and into the ASCII databases nodout and elout. |

Node Cards for Case III (“LOCAL” option). Card 1 for keyword options NODE_LOCAL, NODE_LOCAL_ID, and NODE_SET_LOCAL. Include as many cards as needed to specify all the nodes. This input terminates at the next keyword (“*”) card.

| Card 1c | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|-----|-----|-----|---|---|---|---|
| Variable | ID | CID | REF | HFO | | | | |
| Type | I | I | I | I | | | | |

ID Card for Case III. Additional card for ID option. This card is only used for the NODE_LOCAL_ID keyword option. When activated, each node is specified by a pair of cards consisting of Card 1c, and, secondly, this card. Include as many pairs as needed to specify all the nodes. This input terminates at the next keyword (“*”) card.

| Card 1c.1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-----------|---------|---|---|---|---|---|---|---|
| Variable | HEADING | | | | | | | |
| Type | A70 | | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|-----|---|
| ID | NODE/NODE_SET set ID. The contents of the files are given in Table 14-3 for nodes. See Remark 1 concerning accelerometer nodes. |
| CID | Coordinate system ID for nodal output. See DEFINE_COORDINATE options. |
| REF | Output coordinate system for displacements, velocities, and accelerations. (Nodal coordinates are always in the global coordinate system.) <p>EQ.0: Output is in the local system fixed for all time from the beginning of the calculation. If CID is nonzero, FLAG in the corresponding *DEFINE_COORDINATE_NODES command must be set to 0. FLAG has no bearing on results when REF is set to 1 or 2.</p> <p>EQ.1: Translational output is the projection of the node’s absolute translational motion onto the local system. The local system is defined by the *DEFINE_COORDINATE_NODES command and can change orientation</p> |

| VARIABLE | DESCRIPTION |
|----------|--|
| | <p>according to the movement of the three defining nodes. The defining nodes can belong to either deformable or rigid parts.</p> |
| | <p>EQ.2: Translational output is the projection of the node's relative translational motion onto the local system. Here, "relative" means relative to node N1 of that local system. In other words, the displacement of the origin (node N1) of the local coordinate system is first subtracted from the displacement of the node of interest before projecting it onto the translating and rotating local coordinate system. The local system is defined as described in REF = 1 above. If dynamic relaxation is used, the reference location is reset when convergence is achieved. Rotational output is truly relative to the updated location coordinate system only if REF = 2.</p> |
| HFO | <p>Flag for high frequency output into nodouthf</p> <p>EQ.0: Nodal data written to nodout file only</p> <p>EQ.1: Nodal data also written nodouthf at the higher frequency</p> |
| HEADING | <p>A description of the nodal point. It is suggested that unique description be used. This description is written into the d3hsp file and into the ASCII database nodout.</p> |

Remarks:

1. **Accelerometer.** If a node belongs to an accelerometer, see *ELEMENT_SEATBELT_ACCELEROMETER, and if it also appears as an active node in the NODE_LOCAL or NODE_SET_LOCAL keyword, the coordinate system, CID, transformations will be skipped and the LOCAL option will have no effect.

***DATABASE_MASSOUT**

Purpose: Output nodal masses into ASCII file MASSOUT.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|---|---|---|---|---|
| Variable | SETID | NDFLG | RBFLG | | | | | |
| Type | I | I | I | | | | | |
| Default | 0 | 1 | 0 | | | | | |

VARIABLE**DESCRIPTION**

| | |
|-------|--|
| SETID | Optional set ID. EQ.0: mass output for all nodes, LT.0: no output, GT.0: set ID identifying nodes whose mass will be output. |
| NDFLG | Database extent: EQ.1: output translational mass for deformable nodes identified by SETID (default), EQ.2: output translational mass and rotary inertias for the deformable nodes identified by the SETID. EQ.3: output translational mass for deformable and rigid nodes identified by SETID (default), EQ.4: output translational mass and rotary inertias for the deformable and rigid nodes identified by the SETID. |
| RBFLG | Rigid body data: EQ.0: no output for rigid bodies, EQ.1: output rigid body mass and inertia. |

Remarks:

- Massless Nodes and Rigid Bodies.** Nodes and rigid bodies with no mass are not output. By inference, when the set ID is zero and no output shows up for a node, then the mass of that node is zero.

***DATABASE_NODAL_FORCE_GROUP**

Purpose: Define a nodal force group for output into the ASCII file *nodfor*. The output interval must be specified using **DATABASE_NODFOR* (see **DATABASE_OPTION*).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|---|---|---|---|---|---|
| Variable | NSID | CID | | | | | | |
| Type | I | I | | | | | | |
| Default | none | none | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|------|--|
| NSID | Nodal set ID, see <i>*SET_NODE_OPTION</i> . |
| CID | Coordinate system ID for output of data in local system, |

Remarks:

1. The reaction forces in the global x , y , and z directions (and local x , y , and z directions if CID is defined above) for the nodal force group are written to the *nodfor* file (see **DATABASE_NODFOR*) along with the external work done by these reaction forces. The reaction forces in the global x , y , and z directions for each node in the nodal force group are also written to *nodfor*. These forces can be a result of applied boundary forces such as nodal point forces and pressure boundary conditions, body forces, and contact interface forces. In the absence of body forces, interior nodes would always yield a null force resultant vector. In general this option would be used for surface nodes.

***DATABASE_PAP_OUTPUT**

Purpose: Set contents of output files for pore air pressure calculations.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|-------|-------|--------|---|---|---|
| Variable | IVEL | IACCX | IACCY | IACCZ | NCYOUT | | | |
| Type | I | I | I | I | I | | | |
| Default | 0 | 0 | 0 | 0 | 100 | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| IVEL | Meaning of "Velocity" in d3plot and d3thdt output files EQ.0: Nodal velocity vector EQ.1: Seepage velocity vector |
| IACCX, Y, Z | Meaning of "X/Y/Z-Acceleration" in d3plot and d3thdt output files EQ.0: Not written EQ.21: Nodal air density EQ.22: Nodal pore air pressure EQ.24: Nodal air mass EQ.25: Nodal air mass flow rate |
| NCYOUT | Number of cycles between outputs of calculation status to d3hsp and log files |

*DATABASE_PROFILE

Purpose: Plot the distribution or profile of a data along x , y , or z -direction.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|--------|-----|---|
| Variable | DT | ID | TYPE | DATA | DIR | UPDLOC | MMG | |
| Type | I | I | I | I | I | I | I | |
| Default | none | none | none | none | none | 0 | 0 | |

VARIABLE**DESCRIPTION**

| | |
|------|---|
| DT | Interval time. |
| ID | Set ID. |
| TYPE | Set type: EQ.1: Node Set, EQ.2: Solid Set, EQ.3: Shell Set, EQ.4: Segment Set, EQ.5: Beam Set. |
| DATA | Data type: EQ.1: x -velocity, EQ.2: y -velocity, EQ.3: z -velocity, EQ.4: velocity magnitude, EQ.5: x -acceleration, EQ.6: y -acceleration, EQ.7: z -acceleration, EQ.8: acceleration magnitude, EQ.9: pressure, EQ.10: xx -stress, |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | EQ.11: yy -stress, EQ.12: zz -stress, EQ.13: xy -stress, EQ.14: yz -stress, EQ.15: zx -stress, EQ.16: temperature, EQ.17: volume fraction, EQ.18: kinetic energy, EQ.19: internal energy, EQ.20: density. |
| DIR | Direction: EQ.1: x -direction, EQ.2: y -direction, EQ.3: z -direction, EQ.4: Curvilinear (relative distances between elements of set ID are added up in the order defined by the set) |
| UPDLOC | Flag to update the set location: EQ.0: Only the initial position of set ID is considered EQ.1: The positions of the elements composing the set are updated each DT |
| MMG | Multi-Material ALE group ID. See Remark 2 . GT.0: Multi-Material ALE group ID LT.0: MMG is the ID of a *SET_MULTI-MATERIAL_-GROUP_LIST that can list several Multi-Material ALE group IDs. |

Remarks:

1. **File Description.** At a given time T the profile is written in a file named `profile_DATA_DIR_timeT.xy` (DATA and DIR are replaced by the data and direction names respectively). The file has a xyplot format that LS-PrePost can read and plot. For example, DATA = 9, DIR = 2, and DT = 0.1 sec will save a

pressure profile at $t = 0.0$ sec in profile_pressure_y_time0.0.xy, at $t = 0.1$ sec in profile_pressure_y_time0.1.xy, at $t = 0.2$ sec in profile_pressure_y_time0.2.xy.

- 2. Multi-Material ALE Model.** For the case of a multi-material ALE model (elform = 11 in *SECTION_SOLID or *SECTION_ALE2D or *SECTION_ALE1D), an element can contain several materials with each material being associated with its own pressures and stresses. By default element data is volume averaged before being written out; however, when the multi-material group field, MMG, is set, then element data are output only for the specified materials.

***DATABASE_PWP_FLOW**

Purpose: Request output containing net inflow of fluid at a set of nodes.

Node Sets. Include as many cards as desired. This input ends at the next keyword ("**") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | NSET | | | | | | | |
| Type | I | | | | | | | |
| Default | 0 | | | | | | | |

VARIABLE**DESCRIPTION**

NSET

Node set ID

Remarks:

1. **Inflow.** Net inflow or outflow occurs when maintaining an applied PWP boundary condition causes the addition or removal of water.
2. **Output File.** Output is written to a file named `database_pwp_flow.csv`, a comma-separated ASCII file. Each line consists of (time, flow1, flow2, ...) where flow1 is the total inflow at the node set for the first DATABASE_PWP_FLOW request, flow2 is for the second, etc.

*DATABASE_PWP_OUTPUT

Purpose: Set contents of output files for pore pressure calculations.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|-------|-------|--------|---|---|---|
| Variable | IVEL | IACCX | IACCY | IACCZ | NCYOUT | | | |
| Type | I | I | I | I | I | | | |
| Default | 0 | 0 | 0 | 0 | 100 | | | |

| VARIABLE | DESCRIPTION |
|-------------|--|
| IVEL | <p>Meaning of "Velocity" in d3plot and d3thdt output files</p> <p>EQ.0: Nodal velocity vector</p> <p>EQ.1: Seepage velocity vector</p> |
| IACCX, Y, Z | <p>Meaning of "X/Y/Z-Acceleration" in d3plot and d3thdt output files</p> <p>EQ.0: Not written</p> <p>EQ.1: Total pwp head</p> <p>EQ.2: Excess pwp head (this is also written as temperature)</p> <p>EQ.3: Target rate of volume change</p> <p>EQ.4: Actual rate of volume change</p> <p>EQ.7: Hydraulic pwp head</p> <p>EQ.8: Error in rate of volume change (calculated from seepage minus actual)</p> <p>EQ.9: Volume at node</p> <p>EQ.10: Rate of volume change calculated from seepage</p> <p>EQ.14: Void volume (generated at suction limit)</p> <p>EQ.17: NFIXCON (e.g: +4/-4 for nodes on suction limit)</p> |
| NCYOUT | <p>Number of cycles between outputs of calculation status to d3hsp, log, and tdc_control_output.csv files (time-dependent and steady-state analysis types).</p> |

*DATABASE

*DATABASE_RCFORC_MOMENTS

*DATABASE_RCFORC_MOMENT

Purpose: Define contact ID and nodes for moment calculations. Moments are written to rforc according to output interval given in *DATABASE_RCFORC. If *DATABASE_RCFORC_MOMENT is not used, the moments reported to rforc are about the origin (0,0,0).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-------|-------|---|---|---|---|---|
| Variable | CID | NODES | NODEM | | | | | |
| Type | I | I | I | | | | | |

VARIABLE

DESCRIPTION

| | |
|-------|--|
| CID | Contact ID |
| NODES | Node about which moments are calculated due to contact forces on slave surface. |
| NODEM | Node about which moments are calculated due to contact forces on master surface. |

*DATABASE_RECOVER_NODE

Purpose: Recovers the stresses at nodal points of solid or thin shell elements by using Zienkiewicz-Zhu's Superconvergent Patch Recovery method.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|-----|-----|---|---|---|---|
| Variable | PSID | IAX | IAY | IAZ | | | | |
| Type | I | A | A | A | | | | |
| Default | 0 | 0 | 0 | 0 | | | | |

VARIABLE**DESCRIPTION**

PSID

Part set ID of solid or thin shell elements whose nodal stress will be recovered

IAX, IAY, IAZ

Meaning of "x/y/z-Acceleration" in d3plot and d3thdt output files

EQ.SMNPD: the minimum principal deviator stress

EQ.SMNPR: the minimum principal stress

EQ.SMXPD: the maximum principal deviator stress

EQ.SMXPR: the maximum principal stress

EQ.SMXSH: the maximum shear stress

EQ.SPR: nodal pressure

EQ.SVM: nodal von Mises stress

EQ.SXX: nodal normal stress along x direction

EQ.SYY: nodal normal stress along y direction

EQ.SZZ: nodal normal stress along z direction

EQ.SXY: nodal shear stress along x-y direction

EQ.SYZ: nodal shear stress along y-z direction

EQ.SZX: nodal shear stress along z-x direction

For shell elements append either "B" or "T" to the input string to recover nodal stresses at the bottom or top layer of shell elements. For example, SPRT recovers the nodal pressure at the top layer.

Remarks:

1. Recovered stresses are in global coordinate system.

***DATABASE_SPRING_FORWARD**

Purpose: Create spring forward nodal force file. This option is to output resultant nodal force components of sheet metal at the end of the forming simulation into an ASCII file, SPRING-FORWARD, for spring forward and die corrective simulations.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|---|---|---|---|---|---|
| Variable | IFLAG | | | | | | | |
| Type | I | | | | | | | |

VARIABLE

DESCRIPTION

IFLAG

Output type:

EQ.0: off,

EQ.1: output element nodal force vector for deformable nodes.

***DATABASE_SUPERPLASTIC_FORMING**

Purpose: Specify the output intervals to the superplastic forming output files. The option *LOAD_SUPERPLASTIC_FORMING must be active.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|---|---|---|---|---|---|
| Variable | DTOUT | | | | | | | |
| Type | F | | | | | | | |

VARIABLE**DESCRIPTION**

DTOUT

Output time interval for output to "pressure," "curve1" and "curve2" files. The "pressure" file contains general information from the analysis and the files "curve1" and "curve2" contain pressure as a function of time from phases 1 and 2 of the analysis. The data in the pressure and curve files may be plotted using *ASCII* → *superpl* in LS-PrePost.

***DATABASE_TRACER_{OPTION}**

Purpose: Tracer particles will save a history of either a material point or a spatial point into an ASCII file: trhist. This history includes positions, velocities, and stress components. The option *DATABASE_TRHIST must be active. This option applies to ALE, SPH and DEM (Discrete Element Method) problems.

Available options are:

<BLANK>

DE

The DE option defines a tracer corresponding to discrete elements (*ELEMENT_DISCRETE_SPHERE). See [Remarks 2](#) and [4](#).

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|-----|-----|-----|--------|-----|--------|
| Variable | TIME | TRACK | X | Y | Z | AMMGID | NID | RADIUS |
| Type | F | I | F | F | F | I | I | F |
| Default | 0.0 | 0 | 0.0 | 0.0 | 0.0 | 0 | 0 | 0.0 |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| TIME | Start time for tracer particle |
| TRACK | Tracking option: EQ.0: particle follows material, EQ.1: particle is fixed in space. |
| X | Initial x -coordinate |
| Y | Initial y -coordinate |
| Z | Initial z -coordinate |
| AMMGID | The AMMG ID (ALE multi-material group) of the material being tracked in a multi-material ALE element. See Remark 1 . |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| NID | An optional node ID defining the initial position of a tracer particle. If defined, its coordinates will overwrite the x , y , z coordinates above. This feature is for TRACK = 0 only and can be applied to ALE tracers and DE tracers. See Remark 2 . |
| RADIUS | Radius is used only for the DE option to indicate whether the tracer follows and monitors a single discrete element or multiple discrete elements. GT.0.0: The tracer takes the average results of all discrete elements located inside a sphere with radius = RADIUS. That sphere stays centered on the DE tracer. LT.0.0: The discrete element closest to the tracer is used. The magnitude of RADIUS in this case is unimportant. |

Remarks:

- Multi-Material Groups.** ALE elements can contain multi-materials. Each material is referred to as an ALE multi-material group or AMMG. Each AMMG has its list of history variables that can be output. For example, if a tracer is in a mixed element consisting of 2 AMMGs, and the history variables of AMMG 1 are to be output or tracked, the AMMGID should be defined as AMMGID = 1. If AMMGID = 0, a volume-fraction-weighted-averaged pressure will be reported instead.
- NID Description.** For ALE, NID is a massless dummy node. Its location will be updated according to the motion of the ALE material.

For the DE option, NID is a discrete element node that defines the initial location of the tracer. The DE tracer continues to follow that node if RADIUS < 0. On the other hand, the DE tracer's location is updated according to the average motion of the group of DE nodes inside the sphere defined by RADIUS when RADIUS > 0.

- Tracer Particles in Ambient ALE Elements.** Since the auxiliary variables (6 stresses, plastic strain, internal energy, ...) for ambient elements are reset to their initial values before and after advection and tracer data are stored in trhist during the advection cycle, tracers in ambient elements show the initial stresses, not the current ones.
- Discrete Elements.** If the DE keyword option is used, tracer particles will save a history of either a material point or a spatial point into an ASCII file: demtrh. This history includes positions, velocities components, stress compo-

nents, porosity, void ratio, and coordination number. The option *DATABASE_TRHIST must be active.

***DATABASE_TRACER_GENERATE**

Purpose: Generate tracer particles along an isosurface for a variable defined in the VALTYPE list. The tracer particles follow the motion of this surface and save data histories into a binary file called trcrngen_binout (see [Remarks 4](#) and [5](#)). These histories are identical to the ones output by *DATABASE_TRACER into the trhist file; they include positions, velocities, and stress components. Except for the positions and element ID specifying where the tracer is, the output can be controlled with the VARLOC and VALTYPE2 fields. This option applies to ALE problems.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|-------|----------|-----|--------|--------|------|
| Variable | DT | VALOW | VALUP | VALTYPE1 | SET | SETYPE | MMGSET | UPDT |
| Type | F | F | F | I | I | I | I | F |
| Default | none | 0.0 | 0.0 | none | 0 | 0 | none | DT |

Optional Variable Cards. Cards defining new variables to be output to trcrngen_binout instead of the default ones. Include as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|----------|--------|---|---|---|---|---|
| Variable | VARLOC | VALTYPE2 | MMGSET | | | | | |
| Type | I | I | I | | | | | |
| Default | 0 | 0 | 0 | | | | | |

VARIABLE**DESCRIPTION**

| | |
|-----------------|--|
| DT | Interval time between each tracer generation and position update (See Remark 1). |
| VALOW, VALUP | Range of values between which the isosurface is defined. VALOW is the lower bound while VALUP is the upper bound. See Remark 2 . The value at the isosurface is $0.5(\text{VALOW} + \text{VALUP})$. The variable with this value is defined by VALTYPE. |
| VALTYPE1 | The variable that will be used to generate the isosurfaces. See |

| VARIABLE | DESCRIPTION |
|----------|---|
| | VALTYPE2 for enumeration of values. |
| VALTYPE2 | Data to be output to the trcrngen_binout file. The interpretation of VALTYPE1 and VALTYPE2 is enumerated in the following list: |
| | EQ.1: <i>xx</i> -stress |
| | EQ.2: <i>yy</i> -stress |
| | EQ.3: <i>zz</i> -stress |
| | EQ.4: <i>xy</i> -stress |
| | EQ.5: <i>yz</i> -stress |
| | EQ.6: <i>zx</i> -stress |
| | EQ.7: plastic strain |
| | EQ.8: internal energy |
| | EQ.9: bulk viscosity |
| | EQ.10: relative volume |
| | GE.11 and LE.19: other auxiliary variables |
| | EQ.20: pressure |
| | EQ.21: density |
| | EQ.22: material volume |
| | EQ.23: compression ratio |
| | EQ.24: element volume fraction |
| | EQ.25: nodal volume fraction |
| | EQ.26: <i>x</i> -position |
| | EQ.27: <i>y</i> -position |
| | EQ.28: <i>z</i> -position |
| | EQ.29: <i>x</i> -velocity |
| | EQ.30: <i>y</i> -velocity |
| | EQ.31: <i>z</i> -velocity |
| | EQ.31: velocity |
| | EQ.33: <i>x</i> -acceleration |
| | EQ.34: <i>y</i> - acceleration |
| | EQ.35: <i>z</i> - acceleration |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | EQ.36: acceleration |
| | EQ.37: nodal mass |
| | EQ.38: nodal temperature |
| SET | Set ID (See Remark 2) |
| SETYPE | Type of set (See Remark 2): |
| | EQ.0: solid set |
| | EQ.1: segment set |
| | EQ.2: node set |
| MMGSET | Multi-material group set (See Remark 3). |
| UPDT | Time interval between tracer position update (See Remark 1). |
| VARLOC | Variable location in trcrngen_binout to be replaced with the variable specified in the VALTYPE2 field: |
| | EQ.4: <i>x</i> -velocity |
| | EQ.5: <i>y</i> -velocity |
| | EQ.6: <i>z</i> -velocity |
| | EQ.7: <i>xx</i> -stress |
| | EQ.8: <i>yy</i> -stress |
| | EQ.9: <i>zz</i> -stress |
| | EQ.10: <i>xy</i> -stress |
| | EQ.11: <i>yz</i> -stress |
| | EQ.12: <i>zx</i> -stress |
| | EQ.13: plastic strain |
| | EQ.14: density |
| | EQ.15: relative volume |

Remarks:

1. **DT.** The frequency to create tracers is defined by DT. The default value of UPDT, which is the time interval between updates to the tracer position, is also set to DT. The default behavior, then, is to update tracer positions when a new

tracer is created; however, by setting UPDT to a value less than DT tracer positions can be updated more frequently without creating new tracers.

2. **Tracing Algorithm.** When LS-DYNA adds new tracer particles (see DT), tracers are created at element centers, segment centers, or nodes depending on the set type (SETYPE). A new tracer particle is created when the value at the element center, segment center, or node center is in the bounding interval [VALOW, VALUP], provided that there is *not* already a nearby tracer particle. The tracer particles follow the isosurface defined by the midpoint of the bounding interval $(VALOW + VALUP)/2$.
3. **Multi-Material Groups.** ALE elements can contain several materials. Each material is referred to as an ALE multi-material group. The volume fractions define how much of the element volume is occupied by the groups. Each group has their own variables for $0 < VALTYPE < 26$. If $VALTYPE < 21$ or $VALTYPE = 23$, the variable is volume averaged over the groups defined by MMGSET.
4. **Post-Processing.** The output of *DATABASE_TRACER_GENERATE is written to a file named trcrngen_binout. To access the output in LS-PrePost: *TAB 2* → *LOAD* → *trcrngen_binout* → *trhist* → “*Trhist Data*” window contains a list of variables output for each tracer.
5. **Binary to ASCII File Conversion.** The variables in trhist and trcrngen_binout are arranged in an identical order. Therefore, the trhist can be obtained from the trcrngen_binout file by using the l2a program located at <http://ftp.lstc.com/~user/lstda>.

***DEFINE**

The keyword ***DEFINE** provides a way of defining boxes, coordinate systems, load curves, tables, and orientation vectors for various uses. The keyword cards in this section are defined in alphabetical order:

- *DEFINE_ADAPTIVE_SOLID_TO_DES
- *DEFINE_ADAPTIVE_SOLID_TO_SPH
- *DEFINE_BOX

Unless noted otherwise, an additional option “**TITLE**” may be appended to the ***DEFINE** keywords. If this option is used then an addition line is read for each section in 80a format which can be used to describe the defined curve, table, etc. At present, the title serves no purpose other than to perhaps lend clarity to input decks.

Examples for the ***DEFINE** keyword can be found at the end of this section.

***DEFINE_ADAPTIVE_SOLID_TO_DES_{OPTION}**

Purpose: Adaptively transform a Lagrangian solid part or part set to DES (Discrete Element Sphere) particles (elements) when the Lagrangian solid elements comprising those parts fail. One or more DES particles will be generated for each failed element as debris. The DES particles replacing the failed element inherit the properties of the failed solid element including mass, and kinematical state.

The available options include:

<BLANK>

ID

ID Card. Additional card for the ID keyword option.

VARIABLE**DESCRIPTION**

| | |
|---------|--|
| DID | Definition ID. This must be a unique number. |
| HEADING | Definition descriptor. It is suggested that unique descriptions be used. |
| IPID | ID of the solid part or part set to transform. |
| ITYPE | IPID type: EQ.0: Part ID, NE.1: Part set ID. |
| NQ | Adaptive option for hexahedral elements. For tetrahedral and pentahedral elements, see Remark 1 : EQ.1: Adapt one solid element to one discrete element, EQ.2: Adapt one solid element to 8 discrete elements, EQ.3: Adapt one solid element to 27 discrete elements. |
| IPDES | Part ID for newly generated discrete elements, See Remark 2 . |
| ISDES | Section ID for discrete elements, See Remark 2 . |
| RSF | DES radius scale down factor, which is the ratio of the radius of the generated DES to the calculated radius based on volume consistency. |
| OUTDES | Allow user output generated discrete element nodes and DES properties to a keyword file. EQ.0: No output. (Default) EQ.1: Write data under filename, desvfill.inc |

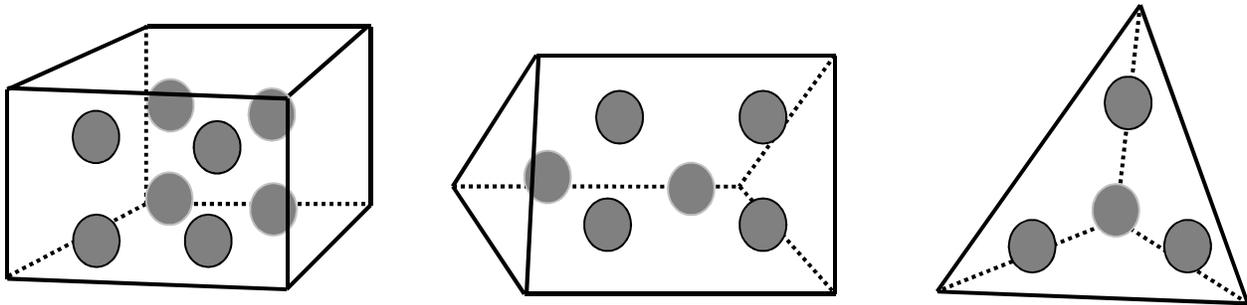

Figure 15-1. Left to right, illustration of conversion from solid to DES for $NQ = 2$ of hexahedron, pentahedron, and tetrahedron elements.

| VARIABLE | DESCRIPTION |
|----------|---|
| IBOND | <p>Allow user define bonds between DES generated from the same solid element.</p> <p>EQ.0: No bonds. (Default)</p> <p>EQ.1: Bonds generated, need to define Card 2.</p> |
| PBN | Parallel-bond modulus [Pa]. See Remark 1 in *DEFINE_DE_BOND. |
| PBS | Parallel-bond stiffness ratio. Shear stiffness/normal stiffness. See Remark 2 in *DEFINE_DE_BOND. |
| PBN_S | Parallel-bond maximum normal stress. A zero value defines an infinite maximum normal stress. |
| PBS_S | Parallel-bond maximum shear stress. A zero value defines an infinite maximum shear stress. |
| SFA | Bond radius multiplier. Default is 1. |
| ALPHA | Numerical damping |

Remarks:

1. **DES Element to Solid Element Ratio.** The DES particles are evenly distributed within the solid element. For hexahedral elements the number of the generated DES particles is $NQ \times NQ \times NQ$. For pentahedral elements, the number of generated DES particles is 1, 6, and 18 for $NQ = 1, 2,$ and 3 respectively. For tetrahedral elements, the number generated DES particles is 1, 4, and 10 for $NQ = 1, 2,$ and 3 respectively. See [Figure 15-1](#).

2. **Part ID.** The Part ID for newly generated DES particles can be either a new Part ID or the ID of an existing DES Part.

***DEFINE_ADAPTIVE_SOLID_TO_SPH_{OPTION}**

Purpose: Create SPH particles to either replace or supplement solid Lagrangian elements.

Applications of this feature include adaptively transforming a Lagrangian solid Part or Part Set to SPH particles, when the Lagrangian solid elements comprising those parts fail. One or more SPH particles (elements) will be generated for each failed element. The SPH particles replacing the failed solid Lagrangian elements inherit all the Lagrange nodal quantities and all the Lagrange integration point quantities of these failed solid elements. Those properties are assigned to the newly activated SPH particles. The constitutive properties assigned to the new SPH part will correspond to the MID and EOSID referenced by the SPH *PART definition. This keyword with options of ICPL = 0, 1 has been extended to 2D cases too.

The available options include:

<BLANK>

VARIABLE

DESCRIPTION

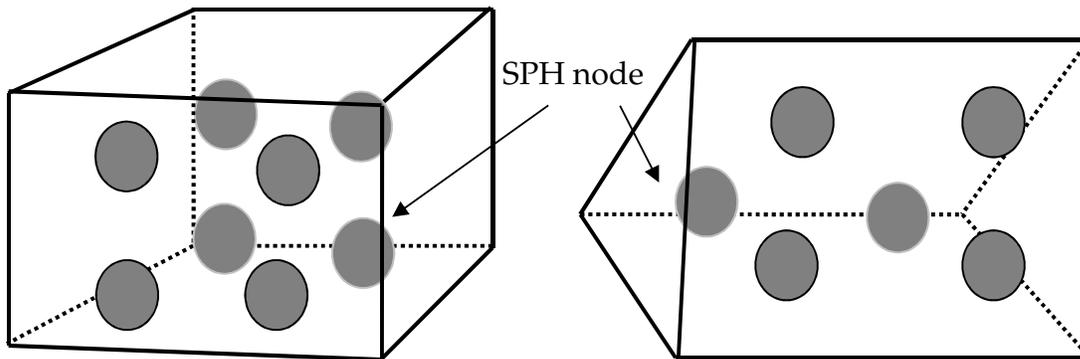

DID

Definition ID. This must be a unique number.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| HEADING | Definition descriptor. It is suggested that unique descriptions be used. |
| IPID | ID of the solid part or part set to transform. |
| ITYPE | IPID type: EQ.0: Part ID, NE.0: Part set ID. |
| NQ | Adaptive option for hexahedral elements. For tetrahedral and pentahedral elements, see Remark 1 : EQ.n: Adapt one 8-node solid element to $(n \times n \times n)$ SPH elements. The range of n is from 1 to 8. |
| IPSPH | Part ID for newly generated SPH elements. See Remark 2 . |
| ISSPH | Section ID for SPH elements. See Remark 2 . |
| ICPL | Coupling of newly generated SPH elements to the adjacent solid elements: EQ.0: Failure without coupling (debris simulation), EQ.1: Coupled to solid element, EQ.3: Provide only thermal coupling between SPH part and solid part (must be combined with IOPT = 0 option; see Remark 4). |
| IOPT | Coupling method: EQ.0: Coupling from beginning (used as constraint between SPH elements and solid elements), EQ.1: Coupling begins when Lagrangian solid element fails. See Remark 3 . |
| CPCD | Thermal coupling conductivity between SPH part and solid part for ICPL = 3 option. The default value is set as the average value of the conductivity from SPH part and the conductivity from solid part. |

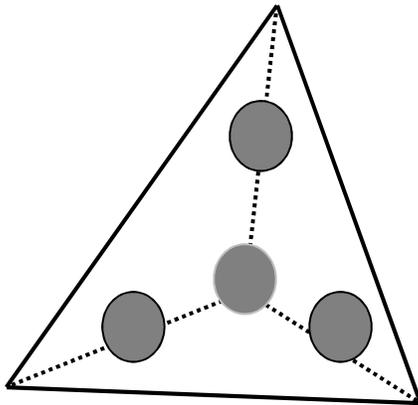

Remarks:

1. **Number of SPH Particles per Element.** The SPH particles are evenly distributed within the solid element. For hexahedral elements the number of the generated SPH particles is $NQ \times NQ \times NQ$. For pentahedral elements, the number of generated SPH particles is 1, 6, and 18 for NQ equal to 1, 2, and 3, respectively. For tetrahedral elements, the number of generated SPH particles is 1, 4, and 10 for NQ equal to 1, 2, and 3, respectively. See [Figure 15-2](#).
2. **SPH Part ID.** The Part ID for newly generated SPH particles can be either a new Part ID or the ID of an existing SPH Part. For constraint coupling, such as when $ICPL = 1$ and $IOPT = 0$, the newly generated SPH part ID should be different from the existing one.

Example of SPH nodes for hexahedral element with $NQ = 2$

Example of SPH nodes for pentahedral element with $NQ = 2$

Example of SPH nodes for tetrahedral element with $NQ = 2$

Figure 15-2. Examples of distributions of SPH particles converted from solid Lagrangian elements.

- Mechanical Failure Coupling.** $ICPL = 0$ is used for debris simulation, so no coupling happens between newly generated SPH particles and solid elements; the user, therefore, needs to define node to surface contact for the interaction between those two parts. When $ICPL = 1$ and $IOPT = 1$, the newly generated SPH particles are bonded with solid elements as one part through the coupling, and the new material ID with different failure criteria can be applied to the newly generated SPH particles.
- Thermal Coupling.** $ICPL = 3$, which must be combined with $IOPT = 0$, is used to thermally couple an SPH part and solid part(s). There is no structural cou-

pling provided. A thermal conductivity value may be defined using the variable CPCD.

*DEFINE

*DEFINE_BEAM_SOLID_COUPLING

*DEFINE_BEAM_SOLID_COUPLING

Purpose: To define a coupling interface between embedded structure and a block defined by solid(s) without sharing nodes.

| PSF | Scale factor for penalty stiffness |

***DEFINE_BOX_{OPTION}**

Available options include:

<BLANK>

LOCAL

Purpose: Define a box-shaped volume. Two diagonally opposite corner points of a box are specified in global or local coordinates if the LOCAL option is active. The box volume is then used for various specifications for a variety of input options, e.g., velocities, contact, etc.

If the option, LOCAL, is active, a local coordinate system with two vectors, see [Figure 15-10](#), is defined. The vector cross product, $z = x \times y$, determines the local z-axis. The local y-axis is then given by $y = z \times x$. A point, X in the global coordinate system is considered to lie with the volume of the box if the coordinate $X - C$, where C is the global coordinate offset vector defined on Card 3, lies within the box after transformation into the local system, $XC_{local} = T \times (X - C)$. The local coordinate, XC_{local} , is checked against the minimum and maximum coordinates defined on Card 1 in the local system. For the *INCLUDE_TRANSFORM options that include translations, rotations and mirrors, all box options are automatically converted from *DEFINE_BOX_xxxx to *DEFINE_BOX_xxxx_LOCAL in the DYNA.INC file. Here, xxxx represents the box options: ADAPTIVE, COARSEN, and SPH, which are defined below. If the transformation matrix of *INCLUDE_TRANSFORM involves using negative values for SCALE, see *DEFINE_TRANSFORMATION, to mirror/reflect an object, the box might not be correctly transformed. Instead of SCALE, it is advised to use the MIRROR option with a7 = 1 for the purpose of mirroring/reflecting.

*DEFINE

*DEFINE_BOX_ADAPTIVE

*DEFINE_BOX_ADAPTIVE_{OPTION}

Available options include:

<BLANK>

LOCAL

Purpose: Define a box-shaped volume enclosing (1) the shells where the h-adaptive level (2) the solids where the tetrahedron r-adaptive mesh size is to be specified. If the midpoint of the element falls within the box, the h-adaptive level is reset. With the additions of LIDX/NDID, LIDY and LIDZ, the box can be made movable; it is also possible to define a fission box followed by a fusion box and the mesh could refine when deformed and coarsen when flattened. Shells falling outside of this volume use the value, MAXLVL, on the *CONTROL_ADAPTIVE control cards. Another related keyword includes: *DEFINE_CURVE_BOX_ADAPTIVITY.

| ZMX | Maximum z-coordinate. Define in the local coordinate system if the option LOCAL is active. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| PID | Deformable part ID. If zero, all active elements within box are considered. |
| LEVEL | Maximum number of refinement levels for elements that are contained in the box. Values of 1, 2, 3, 4,... allow a maximum of 1, 4, 16, 64, ... elements, respectively, to be created for each original element. |
| LIDX/NDID | Load curve ID/Node ID. GT.0: load curve ID. Define adaptive box movement (displacement vs. time) in global X axis. LT.0: absolute value is a node ID, whose translation will be followed by the moving adaptive box. The node ID can be on a moving rigid body. EQ.0: no movement. |
| LIDY | Load curve ID. GT.0: load curve ID. Define adaptive box movement (displacement vs. time) in global Y axis. EQ.0: no movement. |
| LIDZ | Load curve ID. GT.0: load curve ID. Define adaptive box movement (displacement vs. time) in global Z axis. EQ.0: no movement. |
| BRMIN | Minimum mesh size in 3D tetrahedron adaptivity |
| BRMAX | Maximum mesh size in 3D tetrahedron adaptivity |
| XX | X-coordinate on local x-axis. Origin lies at (0,0,0). Define if the LOCAL option is active. |
| YX | Y-coordinate on local x-axis. Define if the LOCAL option is active. |
| ZX | Z-coordinate on local x-axis. Define if the LOCAL option is active. |
| XV | X-coordinate of local x-y vector. Define if the LOCAL option is active. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| YV | Y-coordinate of local x-y vector. Define if the LOCAL option is active. |
| ZV | Z-coordinate of local x-y vector. Define if the LOCAL option is active. |
| CX | X-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active. |
| CY | Y-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active. |
| CZ | Z-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active. |

Remarks:

The moving adaptive box is very useful and efficient in situation where deformation progresses while happening only locally, such as roller hemming and incremental forming simulation. With the moving box feature, elements entering one box can be refined and fused together when they enter another box. Mesh fission outside of the moving box envelope is controlled by MAXLVL and other parameters under *CONTROL_ADAPTIVE. The fusion controls (NCFREQ, IADPCL) can be defined using *CONTROL_ADAPTIVE. Currently, only IADPCL = 1 is supported.

Only when one of the LCIDX/NDID, LICDY, or LCIDZ is defined, the adaptive box will be moving; otherwise it will be stationary.

For 3D tetrahedron r-adaptivity, the current implementation does not support LOCAL option. In card 2, PID, BRMIN and BRMAX are the only parameters currently supported in 3D r-adaptivity.

Example:

Referring to a partial input deck below, and [Figure 15-3](#), a strip of sheet metal is being roller hemmed. The process consists of pre- and final hemming. Each pre- and final roller is defined with a moving adaptive box ID 2 and 3, respectively, with the box shapes shown in [Figure 15-3](#). The first box, a fission box, was set at LEVEL = 3, while the second box, a fusion box, was set at LEVEL = 1. Elements outside of the volume envelope made by the moving boxes undergo no fission and fusion (MAXLVL = 1). This settings allows mesh fission when entering the moving box 2 (LEVEL = 3), fusion only when elements entering the moving box 3 (LEVEL = 1), no fusion/fusion (MAXLVL = 1) at all outside of the volume envelope created by the moving boxes. In

*DEFINE

*DEFINE_BOX_ADAPTIVE

the example, the boxes 2 and 3 are to be moved in global X direction for a distance of 398mm defined by load curve 11, and 450mm defined by load curve 12, respectively.

A moving box can also follow the movement of a node, which can be on a moving rigid body. In this case, load curves defining the boxes' movement can be skipped, instead, NDIDs for the boxes should be defined. For example, in [Figure 15-3](#) and a partial keyword example below, box 2 is to follow a node (ID: 33865) on the pre-roller, and box 3 to follow another node (ID: 38265) on the final roller.

```
*DEFINE_BOX_ADAPTIVE
$#  BOXID  XMN  XMV  YMN  YMV  ZMN  ZMV
   2 -10.00000  36.000000  -15.03000  3.991000  1.00E+00  48.758000
$#  PID  LEVEL  LIDX/NDID  LIDY  LIDZ
   6    3      -33865
*DEFINE_BOX_ADAPTIVE
$#  BOXID  XMN  XMV  YMN  YMV  ZMN  ZMV
   3 -100.00000  -60.00000  -15.03000  3.991000  1.00E+00  48.758000
$#  PID  LEVEL  LIDX/NDID  LIDY  LIDZ
   6    3      -38265
```

Revision information:

The variables LIDX/NDID, LIDY, LIDZ are available in both SMP and MPP starting in Revision 98718.

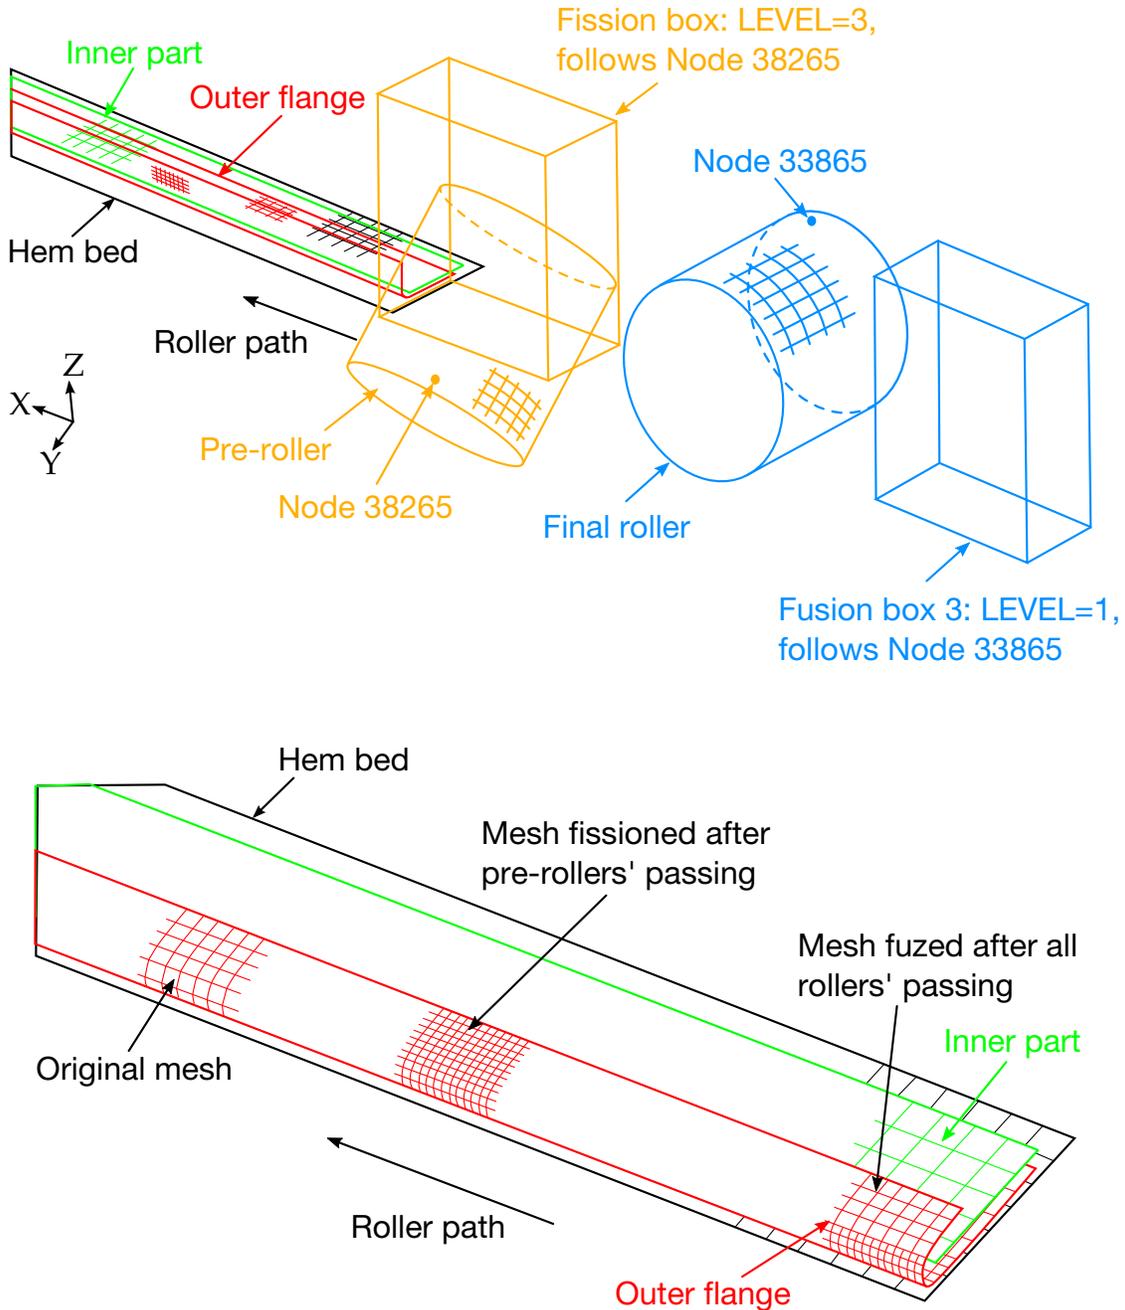

Figure 15-3. Defining mesh fission and fusion.

***DEFINE_BOX_COARSEN_{OPTION}**

Available options include:

<BLANK>

LOCAL

Purpose: Define a specific box-shaped volume indicating elements which are protected from mesh coarsening. See also *CONTROL_COARSEN.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-----|-----|-----|-----|-----|-----|-------|
| Variable | BOXID | XMN | XMN | YMN | YMX | ZMN | ZMX | IFLAG |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| BOXID | Box ID. Define unique numbers. |
| XMN | Minimum x -coordinate. Define in the local coordinate system if the option LOCAL is active. |
| XXM | Maximum x -coordinate. Define in the local coordinate system if the option LOCAL is active. |
| YMN | Minimum y -coordinate. Define in the local coordinate system if the option LOCAL is active. |
| YXM | Maximum y -coordinate. Define in the local coordinate system if the option LOCAL is active. |
| ZMN | Minimum z -coordinate. Define in the local coordinate system if the option LOCAL is active. |
| ZXM | Maximum z -coordinate. Define in the local coordinate system if the option LOCAL is active. |
| IFLAG | Flag for protecting elements inside or outside of box: EQ.0: elements inside the box cannot be coarsened EQ.1: elements outside the box cannot be coarsened |
| XX | X-coordinate on local x -axis. Origin lies at (0,0,0). Define if the LOCAL option is active. |
| YX | Y-coordinate on local x -axis. Define if the LOCAL option is active. |
| ZX | Z-coordinate on local x -axis. Define if the LOCAL option is active. |
| XV | X-coordinate of local xy -vector. Define if the LOCAL option is active. |
| YV | Y-coordinate of local xy -vector. Define if the LOCAL option is active. |
| ZV | Z-coordinate of local xy -vector. Define if the LOCAL option is active. |
| CX | X-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active. |

| VARIABLE | DESCRIPTION |
|----------|--|
| CY | Y-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active. |
| CZ | Z-global coordinate of offset vector to origin of local system. Define if the LOCAL option is active. |

Remarks:

1. **Multiple Boxes.** Many boxes may be defined. If an element is protected by any box then it may not be coarsened.

***DEFINE_BOX_DRAWBEAD**

Purpose: Define a specific box or tube shaped volume around a draw bead. This option is useful for the draw bead contact. If box shaped, the volume will contain the draw bead nodes and elements between the bead and the outer edge of the blank. If tubular, the tube is centered around the draw bead. All elements within the tubular volume are included in the contact definition.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-----|-----|------|-------|--------|-----|---|
| Variable | BOXID | PID | SID | IDIR | STYPE | RADIUS | CID | |
| Type | I | F | F | F | I | F | I | |
| Default | 0 | 0.0 | 0.0 | 0.0 | 4 | 0.0 | 0 | |

VARIABLE**DESCRIPTION**

| | |
|-------|--|
| BOXID | Box ID. Define unique numbers. |
| PID | Part ID of blank. |
| SID | Set ID that defines the nodal points that lie along the draw bead. If a node set is defined, the nodes in the set must be consecutive along the draw bead. If a part or part set is defined, the set must consist of beam or truss elements. Within the part set, no ordering of the elements is assumed, but the number of nodes must equal the number of beam elements plus 1. |
| IDIR | Direction of tooling movement. The movement is in the global coordinate direction unless the tubular box option is active and CID is nonzero. In this latter case, the movement is in the local coordinate direction. EQ.1: tooling moves in x -direction, EQ.2: tooling moves in y -direction, EQ.3: tooling moves in z -direction. |
| STYPE | Set type: EQ.2: part set ID, EQ.3: part ID, |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | EQ.4: node set ID. |
| RADIUS | The radius of the tube, which is centered around the draw bead. Elements of part ID, PID, that lie within the tube will be included in the contact. If the radius is not defined, a rectangular box is used instead. This option is recommended for curved draw beads and for draw beads that are not aligned with the global axes. |
| CID | Optional coordinate system ID. This option is only available for the tubular drawbead. |

***DEFINE_BOX_NODES_ADAPTIVE_{OPTION}**

Purpose: Define adaptive mesh fission and fusion at the beginning of an adaptive step according to a user defined tool moving path and a set of parameters. Sometimes referred as “tube” adaptivity for its adaptive boundary shape, it can help reduce the computational time in incremental forming or roller hemming simulation while maintain accuracy in the area of interest. This is a major improvement over the keyword *DEFINE_BOX_ADAPTIVE for the limitation stated in the [Remarks](#) and in [Figure 15-4](#). Note currently the new feature can only support 2nd level mesh refinement. Other related keywords include: *DEFINE_CURVE_BOX_ADAPTIVITY and *CONTROL_ADAPTIVE_CURVE.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

|----------|------|-------|---|---|---|---|---|---|
| Variable | PID | LEVEL | | | | | | |
| Type | I | I | | | | | | |
| Default | none | none | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|------------------|--|
| BOXID | Box ID. Define unique numbers. |
| NODE | A reference node ID from which the tube will form in front of it, following the tool path described by LCX, LCY and LCZ. |
| LCX, LCY, LCZ | Load curve IDs (as in *DEFINE_CURVE) defining tool moving path in global X, Y, and Z direction, respectively. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| ITYPE | Type of curves LCX, LCY and LCZ. Currently only time vs. displacement load curves are supported. ITYPE.EQ.2: LCX, LCY and LCZ are defined as time vs. displacement. |
| RADIUS | The radius of the tube that defines the fission/fusion boundary. |
| NPIECE | Number of segments used to approximate the tool path in one adaptive step. Note that the tool path curve is divided into a number of linear segments for approximation. |
| PID | The deformable part ID on which the tube adaptivity is to be applied, as in *PART. |
| LEVEL | Desired mesh refinement level; currently maximum of 2 is allowed. |

Remarks:

Metal forming application such as incremental forming and roller hemming simulation are computationally intensive, mostly because of long tool paths and localized deformation. Efforts have been made to increase the efficiency of these application.

The keyword *DEFINE_BOX_ADAPTIVE was one of those attempts. While it offered significant CPU time reduction, the adaptive fission box does not stay in front of the tool when the tool path turns around 180 degree, [Figure 15-4](#) ; likewise, the fusion box, which is supposed to stay behind the tool to coarsen the mesh, does not always stay behind the tool, either. This drawback is addressed by this keyword.

This keyword creates a tube with a user defined radius (RADIUS) that encloses the tool path ahead, and moves along with a reference node (NODE) located on the tool. The mesh is refined in the area in front of the tube (look-forward adaptivity). As the tool moves on, so is the tube. Formed mesh behind the tube is fused according to user set criterion thus saving CPU time required to finish the job, as shown in [Figure 15-5](#).

As described in a detailed numerical investigation conducted using an example of incremental forming [[Reference](#)], a convergence study was first carried out (without the mesh fusion and fission of the tube adaptivity), to obtain the optimum minimum element size, and formability indicators such as minimum shell thickness and maximum effective plastic strain at the end of the simulation. This baseline result was then used to benchmark the parameter study of the tube adaptivity involving mesh fusion and fission. Based on the parameter study, optimum tube radius was

determined as 10 times the final element size (0.9mm), which resulted in 0.3% and 3.4% deviations in thickness and effective plastic strain from the baseline results – an acceptable result. The simulation time reduction was significant, at 46%. The overall CPU time reduction was from 40% to 50% when tube radius decrease from 16mm to 2mm, respectively. On the adaptive time interval ADPFREQ's effect on the CPU time, the paper concluded, the optimum ADPFREQ should be about 1.6% of the total simulation time. Note the ADPFREQ indirectly controls how far the tube will extend in front of the tool.

Future work will include the implementation of multi-level mesh refinement.

Example:

To activate the feature, in addition to using this keyword, *CONTROL_ADAPTIVE also needs to be included. Refer to [Figure 15-5](#) and the keywords below, a fusion/fission tube ID of 2 is created for a part ID 7, with a tube radius of 10.0mm, the reference node ID as 114116. The tube is to follow the tool path defined by load curve IDs of 1, 2 and 3 in the global X, Y and Z directions, respectively. The load curves are defined using time vs. displacement. The tool path curve will be approximated by 8 segments in one adaptive step for the fusion/fission.

***DEFINE_BOX_SPH_{OPTION}**

Available options include:

<BLANK>

LOCAL

Purpose: Define a box-shaped volume. Two diagonally opposite corner points of a box are specified in global coordinates. Particle approximations of SPH elements are computed when particles are located inside the box. SPH particles are deactivated as they leave the box, the deactivated SPH particles can not be reactivated even if they reenter the box. The load curve describes the motion of the maximum and minimum coordinates of the box.

| Default | none | 1.0 |

VARIABLE**DESCRIPTION**

CON_ID

Connection ID, referenced on *MAT_SPOTWELD_DAIMLER-CHRYSLER. Multiple sets of connection data may be used by assigning different connection IDs.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| PRUL | The failure rule number for this connection: EQ.1: Use data of weld partner with lower RANK (default). GE.2: Use *DEFINE_FUNCTION expressions to determine weld data depending on several values of both weld partners. Variables DSIGY, DETAN, DDGPR, DSN, DSB, DSS, DEXSN, DEXSB, DEXSS, and DGFAD must be defined as function IDs, see Remark 5 . |
| AREAEQ | Area equation number for the connection area calculation: EQ.0: (default) $Area_{true} = Area_{modelled}$ EQ.1: millimeter form; see Remark 4 EQ.-1: meter form; see Remark 4 |
| DGTYP | Damage type: EQ.0: no damage function is used EQ.1: strain based damage EQ.2: failure function based damage EQ.3 or 4: fading energy based damage; see Remark 4 |
| MOARFL | Modeled area flag: EQ.0: $Area_{modelled}$ goes down with shear (default) EQ.1: $Area_{modelled}$ stays constant |
| DSIGY | Default yield stress for the spot weld element: GT.0: constant value LT.0: DSIGY references a yield curve or table; see Remark 6 . |
| DETAN | Default tangent modulus for the spot weld element |
| DDGPR | Default damage parameter for hyperbolic based damage function |
| DRANK | Default rank value |
| DSN | Default normal strength |
| DSB | Default bending strength |
| DSS | Default shear strength |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| DEXSN | Default exponent on normal stress term |
| DEXSB | Default exponent on bending stress term |
| DEXSS | Default exponent on shear stress term |
| DLCSN | Default curve ID for normal strength scale factor as a function of strain rate |
| DLCSB | Default curve ID for bending strength scale factor as a function of strain rate. |
| DLCSS | Default curve ID for shear strength scale factor as a function of strain rate |
| DGFAD | Default fading energy for damage type 3 and type 4 |
| DSCLMRR | Default scaling factor for torsional moment in failure function |
| MID | Material ID of the shell material for which properties are defined |
| SIGY | Yield stress to be used in the spot weld element calculation: GT.0: constant value LT.0: SIGY references a yield curve or table; see Remark 6 . |
| ETAN | Tangent modulus to be used in the spot weld element calculation |
| DGPR | Damage parameter for hyperbolic based damage function |
| RANK | Rank value. See Remark 4 . |
| SN | Normal strength |
| SB | Bending strength |
| SS | Shear strength |
| EXSN | Exponent on normal stress term |
| EXSB | Exponent on bending stress term |
| EXSS | Exponent on shear stress term |
| LCSN | Curve ID for normal strength scale factor as a function of strain rate |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| LCSB | Curve ID for bending strength scale factor as a function of strain rate |
| LCSS | Curve ID for shear strength scale factor as a function of strain rate |
| GFAD | Fading energy for damage type 3 and 4 |
| SCLMRR | Scaling factor for torsional moment in failure function |

Remarks:

- Restriction to *MAT_SPOTWELD_DAIMLERCHRYSLER.** This keyword is used only with *MAT_SPOTWELD_DAIMLERCHRYSLER. The data input is used in a 3 parameter failure model. Each solid spot weld element connects shell elements that may have the same or different materials. The failure model assumes that failure of the spot weld depends on the properties of the welded materials, so this keyword allows shell material specific data to be input for the connection. The default data will be used for any spot weld connected to a shell material that does not have material specific data defined, so it is not necessary to define material specific data for all welded shell materials.
- ADD Option.** To simplify data input, the ADD keyword option allows material specific data to be added to an existing *DEFINE_CONNECTION_PROPERTIES table. To use the ADD option, omit Cards 2 and 3, and input only CON_ID on Card 1. Then use Cards 4 and 5 to input material specific data. For each unique CON_ID, control parameters and default values must be input in one set of *DEFINE_CONNECTION_PROPERTIES data. The same CON_ID may be used for any number of sets of material specific data input with the ADD option.
- The Three Parameter Failure Function.** The three parameter failure function is

$$f = \left(\frac{\sigma_n}{\sigma_n^F} \right)^{m_n} + \left(\frac{\sigma_b}{\sigma_b^F} \right)^{m_b} + \left(\frac{\tau}{\tau^F} \right)^{m_\tau} - 1 ,$$

where the three strength terms are SN, SB, and SS, and the three exponents are EXSN, EXSB, and EXSS. The strengths may be a function of strain rate by using the load curves, LCSN, LCSB, and LCSS. The peak stresses in the numerators are calculated from force resultants and simple beam theory.

$$\sigma_n = \frac{N_{rr}}{A}, \quad \sigma_b = \frac{\sqrt{M_{rs}^2 + M_{rt}^2}}{Z}, \quad \tau = \text{SCLMRR} \times \frac{M_{rr}}{2Z} + \frac{\sqrt{N_{rs}^2 + N_{rt}^2}}{A},$$

where the area is the cross section area of the weld element and Z is given by:

$$Z = \pi \frac{d^3}{32} ,$$

where d is the equivalent diameter of the solid spot weld element assuming a circular cross section.

4. **Control Parameters PRUL, AREAQ. And DGTYP.** There are three control parameters that define how the table data will be used for the connection, PRUL, AREAEQ, and DGTYP.

a) *PRUL*. PRUL determines how the parameters will be used. Because each weld connects two shell surfaces, one weld can have two sets of failure data as well as two values for ETAN and SIGY. For PRUL = 1 (default), a simple rule is implemented and the data with the lower RANK will be used. For PRUL = 2 or 3, function expressions can be used to determine the data based on several input values from both weld partners (see [Remark 5](#) for details).

b) *AREAEQ*. The second control parameter is AREAEQ which specifies a rule for calculating a true weld cross section area, A_{true} to be used in the failure function in place of the modeled solid element area, A . For AREAEQ = 1, A_{true} is calculated by

$$A_{\text{true}} = \frac{\pi}{4} (5\sqrt{t_{\text{min shell}}})^2 ,$$

where $t_{\text{min shell}}$ is the thickness of the welded shell surface that has the smaller thickness. For AREAEQ = -1, A_{true} is calculated by

$$A_{\text{true}} = \frac{\pi}{4} \left(\frac{5}{1000} \sqrt{1000 \times t_{\text{min shell}}} \right)^2 ,$$

The equation for AREAEQ = 1 is valid only for a length unit of millimeters, and AREAEQ = -1 is valid only for a length unit of meters.

c) *DGTYP*. The third control parameter, DGTYP, chooses from two available damage types. For DGTYP = 0, damage is turned off and the weld fails immediately when $f \geq 0$. For DGTYP > 0, damage is initiated when $f \geq 0$ and complete failure occurs when $\omega \geq 1$. For DGTYP = 1, damage growth is a function of plastic strain:

$$\omega = \frac{\varepsilon_{\text{eff}}^p - \varepsilon_{\text{failure}}^p}{\varepsilon_{\text{rupture}}^p - \varepsilon_{\text{failure}}^p} , \quad \varepsilon_{\text{failure}}^p \leq \varepsilon_{\text{eff}}^p \leq \varepsilon_{\text{rupture}}^p ,$$

where $\varepsilon_{\text{eff}}^p$ is the effective plastic strain in the weld material. When the value of the failure function first exceeds zero, the plastic strain at failure, $\varepsilon_{\text{failure}}^p$, is set to the current plastic strain, and the rupture strain is offset from the plastic strain at failure by

$$\varepsilon_{\text{rupture}}^p = \varepsilon_{\text{failure}}^p + \text{RS} - \text{EFAIL} ,$$

where RS and EFAIL are the rupture strain and plastic strain at failure which are input on the *MAT_SPOTWELD_DAIMLERCHRYSLER card. If failure occurs when the plastic strain is zero, the weld material yield stress is reduced to the current effective stress such that damage can progress.

For DGTYP = 2, damage is a function of the failure function, f :

$$f \geq 0 \Rightarrow \omega = \frac{f}{f_{\text{rupture}}} ,$$

where f_{rupture} is the value of the failure function at rupture which is defined by

$$f_{\text{rupture}} = \text{RS} - \text{EFAIL} ,$$

and RS and EFAIL are input on the *MAT_SPOTWELD_DAIMLERCHRYSLER card.

Because the DGTYP = 1 damage function is scaled by plastic strain, it will monotonically increase in time. The DGTYP = 2 damage function is forced to be a monotonically increasing function in time by using the maximum of the current value and the maximum previous value. For both DGTYP = 1 and DGTYP = 2, the stress scale factor is then calculated by

$$\hat{\sigma} = \frac{\text{DGPR} \times (1 - \omega)}{\omega \left(\frac{1}{2} + \sqrt{\frac{1}{4} + \text{DGPR}} \right) + \text{DGPR}} \sigma ,$$

This equation becomes nearly linear at the default value of DGPR which is 10^{10} .

For DGTYP = 3, damage is a function of total strain:

$$\omega = \frac{\Delta\varepsilon_n}{\Delta\varepsilon_{\text{fading}}} .$$

$\Delta\varepsilon_n$ is the accumulated total strain increment between moment of damage initiation (failure) and current time step t_n

$$\Delta\varepsilon_n = \Delta\varepsilon_{n-1} + \Delta t_n \sqrt{\frac{2}{3} \text{tr}(\dot{\varepsilon}_n \dot{\varepsilon}_n^T)} , \quad \Delta\varepsilon|_{t_{\text{failure}}} = 0 ,$$

and $\Delta\varepsilon_{\text{fading}}$ is the total strain increment for fading (reduction of stresses to zero)

$$\Delta\varepsilon_{\text{fading}} = \frac{2 \times \text{GFAD}}{\sigma_{\text{failure}}} ,$$

where GFAD is the fading energy from input and σ_{failure} is the effective stress at failure. The stress scale factor is then calculated by a linear equation

$$\hat{\sigma} = (1 - \omega)\sigma ,$$

where σ is the Cauchy stress tensor at failure and ω is the actual damage value. Problems can occur, if the loading direction changes after the onset of failure, since during the damage process, the components of the stress tensor are kept constant and hence represent the stress state at failure.

DGTYP = 4 should be used when describing the damage behavior of the spotweld in a more realistic way. For DGTYP = 4, damage is a function of the internal work done by the spotweld after failure,

$$\hat{\sigma} = (1 - \omega)\sigma^{\text{ep}}, \quad \omega = \frac{G_{\text{used}}}{2 \times \text{GFAD}}, \quad G_{\text{used}} = G_{\text{used}}^{n-1} + \det \left(F_{ij} \sigma_{ij}^{\text{ep}} \Delta \varepsilon_{ij} \right) .$$

In the above, F_{ij} is the deformation gradient. σ^{ep} is a scaled Cauchy stress tensor based on the undamaged Cauchy stress tensor σ^{wd} and scaled in such a way that the same internal work is done in the current time step as in the time step before (equipotential):

$$\sigma^{\text{ep}} = \alpha \sigma^{\text{wd}}, \quad \alpha = \frac{\sigma_{ij}^{n-1, \text{ep}} \Delta \varepsilon_{ij}}{\sigma_{ij}^{\text{wd}} \Delta \varepsilon_{ij}} .$$

5. **Failure Rule from *DEFINE_FUNCTION.** The failure rule number PRUL = 2 or 3, is available starting with Release R7. To use this new option, 11 fields must be defined as function IDs: DSIGY, DETAN, DDGPR, DSN, DSB, DSS, DEXSN, DEXSB, DEXSS, DGFAD, and DSCLMRR.

These functions depend on:

- (t1, t2) = thicknesses of both weld partners
- (sy1, sy2) = initial yield stresses at plastic strain
- (sm1, sm2) = maximum engineering yield stresses
- r = strain rate
- a = spot weld area
- fn = normal term in failure function
- fb = bending term in failure function
- fs = shear term in failure function

For DSIGY = 100, such a function could look like:

```
*DEFINE_FUNCTION
      100
func (t1, t2, sy1, sy2, sm1, sm2, r, a, fn, fb, fs) = 0.5 * (sy1 + sy2)
```

All the listed arguments in their correct order must be included in the argument list. For PRUL = 2, the thinner part is the first weld partner. For

PRUL = 3, the bottom part (nodes 1-2-3-4) is the first weld partner. Since material parameters must be identified from both weld partners during initialization, this feature is only available for a subset of material models at the moment, namely material types 24, 120, 123, and 124. This new option eliminates the need for the ADD option.

6. **Yield Curve or Table for SIGY.** When using this option, a simplified plasticity algorithm is used, assuming a linear behavior within one time increment. Thus, no iterative return mapping has to be performed.

***DEFINE_CONSTRUCTION_STAGES**

Purpose: Define times and durations of construction stages.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|-----|-----|------|-----|-----|---|---|
| Variable | ISTAGE | ATS | ATE | ATR | RTS | RTE | | |
| Type | I | F | F | F | F | F | | |
| Default | none | 0.0 | 0.0 | none | ATS | ATE | | |

| VARIABLE | DESCRIPTION |
|-----------------|---------------------------------|
| ISTAGE | Stage ID |
| ATS | Analysis time at start of stage |
| ATE | Analysis time at end of stage |
| ATR | Analysis time duration of ramp |
| RTS | Real time at start of stage |
| RTE | Real time at end of stage |

Remarks:

- 1. Related Keywords.** See also *CONTROL_CONSTRUCTION_STAGES and *DEFINE_STAGED_CONSTRUCTION_PART.
- 2. Stage Start and End Times.** The first stage should start at time zero. There must be no gaps between stages, that is, ATS for each stage must be the same as ATE for the previous stage.
- 3. Ramp Time.** The ramp time allows gravity loading and part removal to be applied gradually during the first time period ATR of the construction stage.
- 4. Analysis and Real Time.** The analysis always runs in “analysis time” – typically measured in seconds. The “real time” is used only as a number to appear on output plots and graphs and is completely arbitrary. A dynain file is written at the end of each stage. See ITIME on *CONTROL_STAGED_CONSTRUCTION.

*DEFINE

*DEFINE_CONTACT_EXCLUSION

*DEFINE_CONTACT_EXCLUSION

Purpose: Exclude tied nodes from being treated in specific contact interfaces. This keyword is currently only available in the MPP version.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-------|---|---|---|---|---|---|

VARIABLE

DESCRIPTION

EID

Exclusion ID

TITLE

Exclusion Title

TARGET

Contact interface from which tied nodes are to be excluded. This must be the ID of a SINGLE_SURFACE, NODE_TO_SURFACE, or SURFACE_TO_SURFACE contact with SOFT ≠ 2.

C_i

The IDs of TIED contacts: 7 on the first card and 8 per additional card for as many cards as necessary. Any node which is a slave node in one of these interfaces, and is in fact tied, will not be processed (as a slave node) in the TARGET interface.

Remarks:

1. **Contact Forces on Excluded Nodes.** If a node is excluded from the Target by this mechanism, contact forces may still be applied to the node due to any slave or master nodes impacting the contact segments of which it is a part (no contact SEGMENTS are deleted, only contact NODES).
2. **SURFACE_TO_SURFACE Target.** If the TARGET contact is of type SURFACE_TO_SURFACE, any tied slave nodes are deleted from both the slave side (for the normal treatment) and the master side (for the symmetric treatment).

*DEFINE

*DEFINE_CONTACT_VOLUME

*DEFINE_CONTACT_VOLUME

Purpose: Define a rectangular, a cylindrical, or a spherical volume in a local coordinate system. The volume can be referenced by *SET_NODE_GENERAL for the purpose of defining a node set consisting of nodes inside the volume, or by *CONTACT_... for the purpose of defining nodes or segments on the slave side or the master side of the contact (see SBOXID and MBOXID on Card 1 of *CONTACT_...).

VARIABLE

DESCRIPTION

| | |
|--------|--|
| RINNER | Inner radius of sphere. |
| ROUTER | Outer radius of sphere. |
| D_ANGS | If the included angle between a line draw from the center of the sphere to the centroid of the segment and the normal vector to the contact segment is <i>greater</i> than this angle, the segment is deleted. |

***DEFINE_COORDINATE_NODES**

Purpose: Define a local coordinate system with three node numbers. The local cartesian coordinate system is defined in the following steps. If the primary direction is along the x -axis, then the z -axis is computed from the cross product of x and \bar{y} , $z = x \times \bar{y}$ (see [Figure 15-6](#)); the y -axis is, then, computed as $y = z \times x$. A similar procedure applies if the local axis is along the y or z axes.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|-----|---|---|
| Variable | CID | N1 | N2 | N3 | FLAG | DIR | | |
| Type | I | I | I | I | I | A | | |
| Default | none | none | none | none | 0 | X | | |

VARIABLE**DESCRIPTION**

| | |
|------|---|
| CID | Coordinate system ID. A unique number has to be defined. |
| N1 | ID of node located at local origin. |
| N2 | ID of node located along local x -axis if $DIR = X$, the y -axis if $DIR = Y$, and along the z -axis if $DIR = Z$. |
| N3 | ID of node located in local x - y plane if $DIR = X$, the local y - z plane if $DIR = Y$, and the local z - x plane if $DIR = Z$. |
| FLAG | Set to unity, 1, if the local system is to be updated each time step. Generally, this option when used with nodal SPC's is <i>not recommended</i> since it can cause excursions in the energy balance because the constraint forces at the node may go through a displacement if the node is partially constrained. |
| DIR | Axis defined by node N2 moving from the origin node N1. The default direction is the x -axis. |

Remarks:

The nodes N1, N2, and N3 must be separated by a reasonable distance and not collinear to avoid numerical inaccuracies.

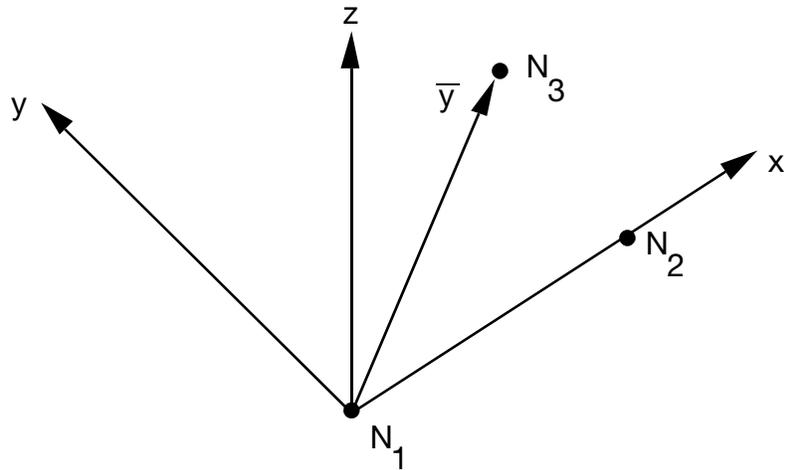

Figure 15-6. Definition of local coordinate system using three nodes when the node N2 lies along the x -axis.

***DEFINE_COORDINATE_SYSTEM_{OPTION}**

Available options include:

<BLANK>

IGES

Purpose: Define a local coordinate system.

This card implements the same method as *DEFINE_COORDINATE_NODES; but, instead of reading coordinate positions from nodal IDs, it directly reads the three coordinates from its data cards as Cartesian triples.

When the IGES option is active, LS-DYNA will generate the coordinate system from an IGES file containing three straight curves representing the x, y, and z axes. See [remark 4](#).

|----------|----------|---|---|---|---|---|---|---|
| Variable | FILENAME | | | | | | | |
| Type | C | | | | | | | |
| Default | none | | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| CID | Coordinate system ID. A unique number has to be defined. |
| XO | X-coordinate of origin. |
| YO | Y-coordinate of origin. |
| ZO | Z-coordinate of origin. |
| XL | X-coordinate of point on local x-axis. |
| YL | Y-coordinate of point on local x-axis. |
| ZL | Z-coordinate of point on local x-axis. |
| CIDL | Coordinate system ID applied to the coordinates used to define the current system. The coordinates X0, Y0, Z0, XL, YL, ZL, XP, YP, and ZP are defined with respect to the coordinate system CIDL. |
| XP | X-coordinate of point in local x-y plane. |
| YP | Y-coordinate of point in local x-y plane. |
| ZP | Z-coordinate of point in local x-y plane. |
| FILENAME | Name of the IGES file containing three curves (see Remarks below). |

Remarks:

1. The coordinates of the points must be separated by a reasonable distance and not co-linear to avoid numerical inaccuracies.

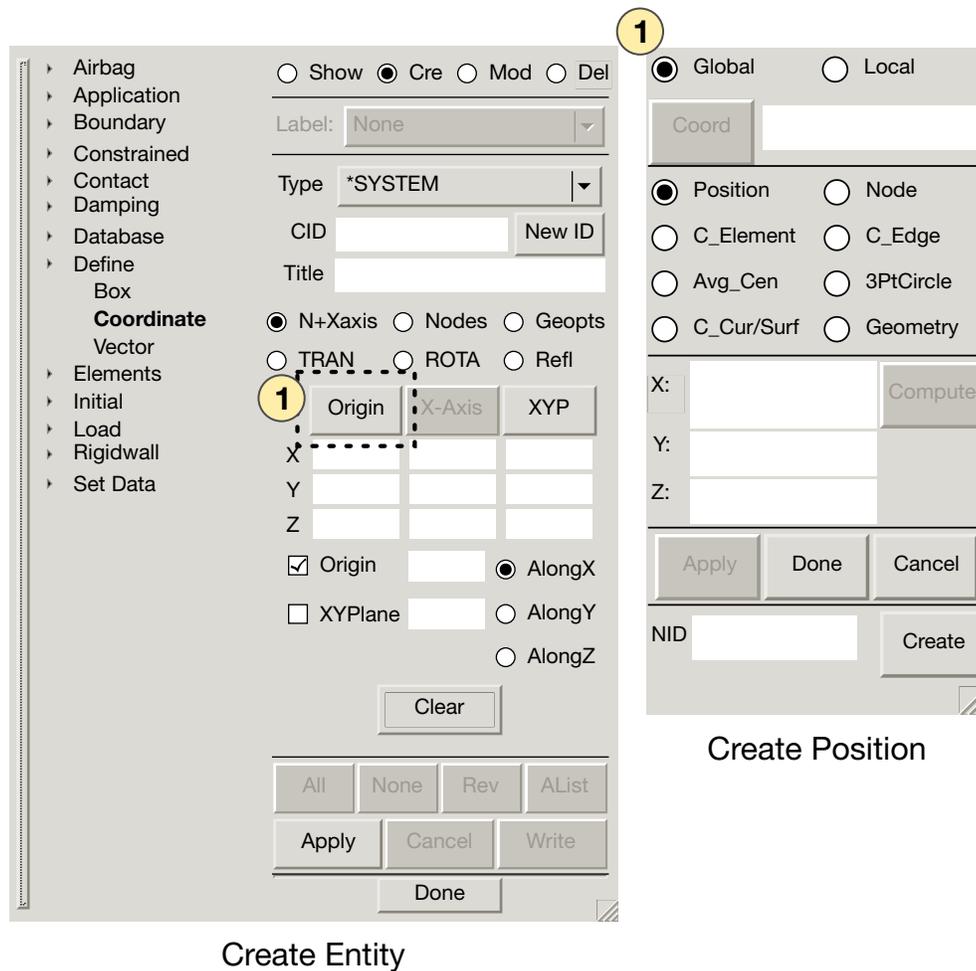

Figure 15-7. LS-PrePost4.0 Dialog for defining a coordinate system.

2. Care must be taken to avoid chains of coordinate transformations because there is no guarantee that they will be executed in the correct order.
3. **LS-PrePost.** A coordinate system can be created using the dialog box located at *Model* (main window) → *CreEnt* → *Define* (see the left pane) → *Coordinate*. This will activate a *Define Coordinate* dialog in the right pane. Select the *Cre* radio button at the top of the right pane, and set the *type* dropdown to **SYSTEM*. The next set of radio buttons (below the title input box) sets the method used to define the coordinate system. See [Figure 15-7](#).
 - a) The *N+Xaxis* method generates a coordinate system from based on:
 - i) a user specified origin,
 - ii) one of the three global axes (this is a *severe* restriction), and
 - iii) a 3rd point.

The image shows a dialog box for defining a coordinate system. It has three radio buttons at the top: 'N+Xaxis', 'Nodes' (which is selected), and 'Geopts'. Below these are three more radio buttons: 'TRAN', 'ROTA', and 'RefI'. There are three columns labeled 'Origin', 'X-Axis', and 'XYP'. Below these columns are three rows labeled 'X', 'Y', and 'Z'. There are three checkboxes: 'Origin' (checked), 'X-Axis', and 'XYPlane'. There is a 'Direction' dropdown menu currently set to 'X'. At the bottom is a 'Clear' button.

Figure 15-8. Subset of *Create Entity* dialog for both *Nodes* and *Geopts* methods.

The 3rd point, together with the specified global axis defines the new system's x-y plane. The remaining axes are derived using orthogonality and right-handedness. This method requires the user to pick two points which involves the *Create Position* dialog box, as shown in the left frame of [Figure 15-7](#).

NOTE: After defining each point in the *Create Position* dialog, it is *very important* to use the *done* button. The *Create Entity* dialog stays up and remains interactive while the *Create Position* dialog is also up and interactive. This can be confusing. Returning to the *Create Entity* dialog without choosing *done* is a common mistake.

- b) The *node* method generates a coordinate system from three points:
 - i) The first point specifies the origin.
 - ii) The first and second points together specify the x-axis.
 - iii) The three points together specify the x-y plane of the new coordinate system. The y and z axis are derived from orthogonality and right-handedness.
- c) The *Geopts* option generates the new coordinate system from a global axis and two points. With this method the new system's z-axis is set from the *Direction* drop-down. This new system's x-y plane is, then, orthogonal to the chosen direction. The remaining two points serve to define the origin and the x-axis (by projecting the second point). This option is useful for metal forming application, since, often times, only the z-axis is important while the while the x and y axes are not.

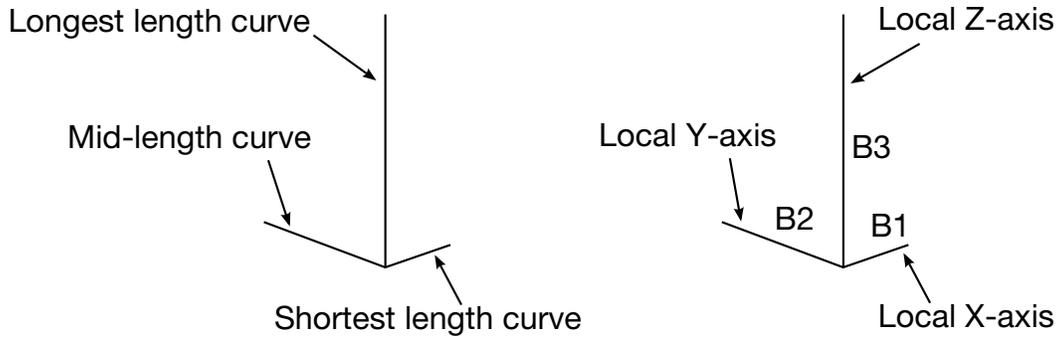

Figure 15-9. Input curves (left). The generated local coordinate system is written to the d3plot file as a part consisting of three beams (right).

4. **IGES.** When option, IGES, is used, three curves in the IGES format will be used to define a local coordinate system. IGES curve entity types 126, 110 and 106 are currently supported. Among the three curves, the longest length will be made as local Z-axis, the mid-length will be Y-axis and the shortest length X-axis. Suggested X, Y and Z-axis length is 100mm, 200mm and 300mm, respectively.

All the three curves must have one identical point, and will be used for the origin of the new local coordinate system. The coordinate system ID for the local system will be based on the IGES file name. The IGES file name must start with a number, followed by an underscore “_”, or by a dot. The number preceding the file name will be used as the new local coordinate system ID, which can then be referenced in *MAT_20 cards, for example.

After the LS-DYNA run, three beam elements of a new PID will be created in place of the three curves representing the local X, Y, and Z-axis in the d3plot file for viewing in LS-PrePost. See [Figure 15-9](#).

The following partial input contains an example in which the keyword is used to create a local coordinate system (CID = 25) from IGES input. The IGES file named, 25_iges, contains three intersecting curves in one of the three supported IGES entity types. The example demonstrates using the IGES coordinate system (ID = 25) to specify the local coordinate system for a rigid body (PID = 2, MID = 2). The keyword, *BOUNDARY_PRESCRIBED_MOTION_RIGID_LOCAL, then uses this local coordinate system to assign velocities from load curves 3 and 5 for the rigid body motion in the local x-direction.

The keyword can be repeated for each new coordinate system if multiple coordinate systems are needed.

Revision information:

This option is available starting in LS-DYNA Revision 62798.

***DEFINE_COORDINATE_VECTOR**

Purpose: Define a local coordinate system with two vectors, see [Figure 15-10](#). The vector cross product, $\mathbf{z} = \mathbf{x} \times \mathbf{v}_{xy}$ where \mathbf{v}_{xy} is a vector in the xy -plane, determines the z -axis. The y -axis is then given by $\mathbf{y} = \mathbf{z} \times \mathbf{x}$. If this coordinate system is assigned to a nodal point, then at each time step during the calculation, the coordinate system is incrementally rotated using the angular velocity of the nodal point to which it is assigned.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-----|-----|-----|-----|
| Variable | CID | XX | YX | ZX | XV | YV | ZV | NID |
| Type | I | F | F | F | F | F | F | I |
| Default | 0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0. |

VARIABLE**DESCRIPTION**

| | |
|-----|--|
| CID | Coordinate system ID. A unique number has to be defined. |
| XX | X-coordinate on local x -axis. Origin lies at (0,0,0). |
| YX | Y-coordinate on local x -axis |
| ZX | Z-coordinate on local x -axis |
| XV | X-coordinate of local xy -vector |
| YV | Y-coordinate of local xy -vector |
| ZV | Z-coordinate of local xy -vector |
| NID | Optional nodal point ID. The coordinate system rotates with the rotation of this node. If the node is not defined, the coordinate system is stationary. See Remark 2 . |

Remarks:

1. **Numerical Inaccuracies.** These vectors should be separated by a reasonable included angle to avoid numerical inaccuracies.

- 2. Rotation.** Ideally, this nodal point should be attached to a rigid body or a structural part where the nodal point angular velocities are meaningful. It should be noted that angular velocities of nodes may not be meaningful if the nodal point is attached only to solid elements and even to shell elements where the drilling degree of freedom may be singular, which is likely in flat geometries.

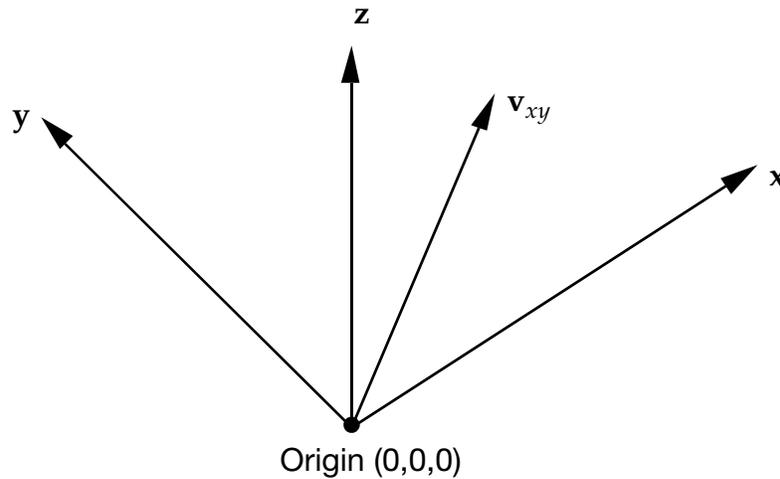

Figure 15-10. Definition of the coordinate system with two vectors.

***DEFINE_CPM_BAG_INTERACTION**

Purpose: To model energy flow from a master airbag to a slave airbag. The master must be an active particle airbag and the slave a control volume (CV) airbag converted from a particle bag.

To track the flow of energy, LS-DYNA automatically determines which vent parts are common to both airbags. At each time step the energy that is vented through the common vents is subtracted from the master and added to the slave. In turn, the slave bag’s pressure provides the downstream pressure value for the master bag’s venting equation. While this model accounts for energy flow from master to slave, it ignores flow from slave to master.

If CHAMBER is used for the slave CV bag, see [Remark 1](#).

|-----------------|---|
| BAGID1 | Airbag ID of master CPM particle bag |
| BAGID2 | Airbag ID of slave CV bag switched from CPM bag |
| NSPEC | The location of the 1 st gas component from the CPM bag to be filled in the CV bag. See Remark 2 . |

Remarks:

- Chambers.** Due to the complexity of the bookkeeping, the slave may have several chambers but only one of the chambers is allowed to interact with the master bag. This chamber will be searched automatically through the commonly shared parts.
- NSPEC.** If NSPEC equals zero, the mass and energy vented out from the CPM bag will be directly fed into the CV bag. This is assuming these two bags have the same gas species.

If the CPM bag and the CV bag contain different gas initially, the gas species of CPM bag must be listed after the inflator gas species of the CV bag. The order of the gas components should be the same. NSPEC gives the first location of the CPM gas in the CV gas species list.

***DEFINE_CPM_CHAMBER**

Purpose: To define airbag chambers for air particle initialization or chamber interaction.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|---|---|---|---|---|---|
| Variable | ID | NCHM | | | | | | |
| Type | I | I | | | | | | |
| Default | none | 0 | | | | | | |

Chamber Definition Card Sets:

Add NCHM chamber definition card sets. Each chamber definition card set consists of a Chamber Definition Card followed by NINTER Interaction Cards.

Chamber Definition Card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|--------|--------|---|---|---|---|
| Variable | SID1 | SID2 | NINTER | CHM_ID | | | | |
| Type | I | I | I | I | | | | |
| Default | none | 0 | 0 | 0 | | | | |

Interaction Cards. Add NINTER of these. If NINTER = 0, skip this card.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|-------|---|---|---|---|---|
| Variable | SID3 | ITYPE3 | TOCHM | | | | | |

| Default | none | none | none | | | | | |

LS-DYNA keyword deck by LS-PrePost

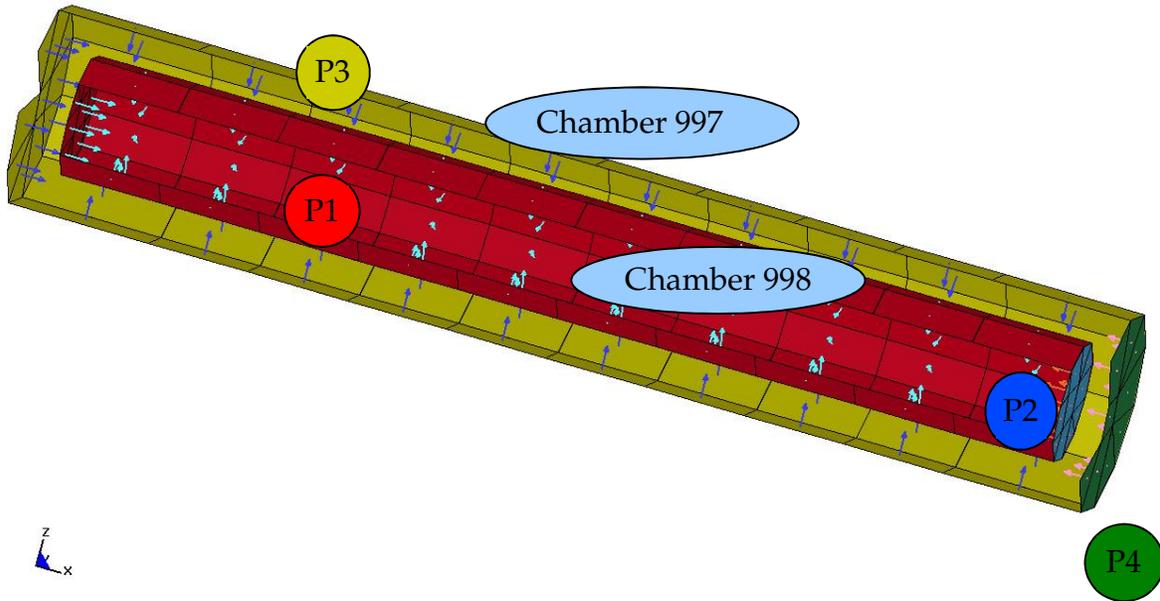

Figure 15-11.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| ID | Unique ID for this card |
| NCHM | Number of chambers defined in this card |
| SID1 | Part set defining all parts that constitute the chamber volume. See Remark 1 . |
| SID2 | Part set defining the parts whose shell normal vectors need to be flipped, such as separation walls between chambers. See Remark 1 . |
| NINTER | Number of vent hole definition for chamber interaction. |
| CHM_ID | Chamber ID (see Remark 2) |
| SID3 | Set defining interaction between chambers |
| ITYPE3 | Set type: EQ.0: Part EQ.1: Part set |
| TOCHM | The chamber ID of the connected chamber |

Remarks:

1. **Normal Vectors.** Each chamber's volume is calculated based on the part normals pointed inwards. So SID1 would normally have parts with their shell normals pointing inwards. But in some cases, parts may be shared by more than one chamber. In this case, the shell orientation of certain part(s) may need to be flipped for the other chambers in question. In such cases, SID2 can be used to flip the shell-normals for specific parts.

```

```

2. **Particle Collisions.** Particles with different chamber ID will not interact in particle to particle collision. This feature will allow program to distinguish particles separated by a thin wall.
3. **Output Files.** All chambers data are output to lsda binout database. The utility "l2a" can convert it into abstat_chamber ASCII file and process with LS-PrePost under abstat format

*DEFINE

*DEFINE_CPM_GAS_PROPERTIES

*DEFINE_CPM_GAS_PROPERTIES

Purpose: To define extended gas thermodynamic properties.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-----|-----|-----|-----|-----|---|
| Variable | ID | XMM | CP0 | CP1 | CP2 | CP3 | CP4 | |
| Type | I | F | F | F | F | F | F | |
| Default | none | none | 0. | 0. | 0. | 0. | 0. | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|--------|------|---|
| Variable | MUT0 | MUT1 | MUT2 | MUT3 | MUT4 | CHM_ID | VINI | |
| Type | F | F | F | F | F | I | F | |
| Default | 0. | 0. | 0. | 0. | 0. | 0 | 0. | |

| <u>VARIABLE</u> | <u>DESCRIPTION</u> |
|-----------------|---|
| ID | Unique ID for this card |
| XMM | Molar mass |
| CP0, ..., CP4 | Coefficients of temperature dependent specific heat with constant pressure $C_p(T) = C_{p0} + C_{p1}T + C_{p2}T^2 + C_{p3}T^3 + C_{p4}T^4$ |
| MUT0, ..., MUT4 | Coefficients of temperature dependent Joule-Thomson effect $\mu_t(T) = \mu_{t0} + \mu_{t1}T + \mu_{t2}T^2 + \mu_{t3}T^3 + \mu_{t4}T^4$ |
| CHM_ID | Chamber ID (see Remark 1) |
| VINI | Initial volume for user defined inflator (see Remark 1) |

Remarks:

1. **User Defined Routines.** If CHM_ID and VINI are defined, this gas property will be used in the user_inflator routine which is provided in the dyn21b.f of general usermat package. The code will give current chamber volume, pressure, temperature and time step and expects a return value of change of chamber, burned gas temperature and mass flow rate to feedback to the code for releasing particles. All state data for this chamber will be output in binout under the abstat_chamber subdirectory.

Example:

```

| Type | I | I | I | I | I | I | F | I |
| Default | 0 | none | none | none | none | none | 0. | none |

Optional card: When VANG equals -2, NID1-NID3 will define a moving coordinate system for the direction of flow through the vent.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|---|---|---|---|---|
| Variable | NID1 | NID2 | NID3 | | | | | |
| Type | I | I | I | | | | | |
| Default | none | none | none | | | | | |

VARIABLE

DESCRIPTION

| | |
|--------|---|
| ID | Unique ID for this card |
| C23 | Vent hole coefficient. This is the Wang-Nefske leakage parameter. (Default = 1.0) |
| LCTC23 | Load curve defining vent hole coefficient as a function of time. |

| VARIABLE | DESCRIPTION |
|----------|---|
| LCPC23 | Load curve defining vent hole coefficient as a function of pressure. |
| ENH_V | Enhance venting option. Default = 0; however, if the Joule-Thomson effect is enabled, this field will be set to 1 automatically. EQ.0: disable EQ.1: enable |
| PPOP | Pressure difference between interior and ambient pressure to open the vent hole. Once the vent is open then it will stay open. |
| C23UP | Scale factor of C23 while switching from CPM to uniform pressure calculation. |
| IOPT | Directional venting: EQ.1: In shell normal EQ.2: Against shell normal One-way venting: EQ.10: In shell normal EQ.20: Against shell normal Special vent option: EQ.100: Enable compression seal vent. Vent area is adjusted according to the formula below. (Remark 1) $A_{\text{vent}} = \max(A_{\text{current}} - A_0, 0)$ EQ.200: Enable push-out vent. Particle remains active while going through this external vent within the range of 2 times of its characteristic length, l_{vent} . $l_{\text{vent}} = \sqrt{A_{\text{vent}}}$ |
| JT | Include the Joule-Thomson effect. When the Joule-Thomson effect is enabled, ENH_V is automatically set to 1 (enable). EQ.0: disable EQ.1: use part pressure EQ.2: use chamber pressure |
| IDS1 | JT's up stream condition part ID/chamber ID |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| IDS2 | JT's downstream condition part ID/chamber ID |
| IOPT1 | Upstream chamber ID for one-way vent hole. This will help the code to determine the probability function. |
| PID1, PID2 | When specified, the vent probability function is evaluated from the difference of local part pressures between PID1 and PID2 instead of the usual calculation involving the chamber pressure. This option is usually used for vents near a long sleeve which causes unrealistic venting using chamber pressure alone. |
| VANG | Cone angle in degrees. Particle going through this vent will be redirected based on this angle. This option is only valid for an internal vent. (VANG < 0, Remark 2) GT.0.0: cone angle (maximum 270°) EQ.0.0: disabled (Default) EQ.-1.0: direction follows the vent normal EQ.-2.0: direction follows local coordinates system defined by three nodes |
| LCRED | Time dependent probability curve to control CPM particle through the internal vent with VANG option. (Remark 3) |
| NID1-NID3 | Three nodes define a moving coordinate system for the direction of flow through the vent when VANG equals -2. |

Remarks:

1. **Compression Seal Vent Model.** In order to evaluate bag state variables correctly, the CPM domain needs to be a closed surface for the volume to be well-defined. If the model contains a flap vent which is free to open and close, this option will correctly maintain the bag's integrity.

Example:

```
*AIRBAG_PARTICLE
$====1====$====2====$====3====$====4====$====5====$====6====$====7====$====8====
```

```

1010      1      1011      1      0      0.0      0.0      1
100000    0      1      300.0    1.0e-04    1
1         1      1
61        0      -9910
1.0E-04   300.0  2.897E-2  2.671E+1  7.466E-3 -1.323E-6
1000      1001   4.0E-3    20.79
3000001   1.0
$=====
*DEFINE_CPM_VENT
$====1====$====2====$====3====$====4====$====5====$====6====$====7====$====8====
9910      1.0      0      0      1      0.0
1         51      2

```

2. **VANG < 0.** All particles passing through vent are in a collinear stream following venting direction with no spread or effectively a zero degree angle. The dispersion of the particles after the vent is result of the particle to particle collision.
3. **LCRED.** If the curve is given, particle passing through vent is evaluated by this time dependent probability function whether applying VANG option or not. User can use this option to strengthen or weaken the directional vent stream.

***DEFINE_CURVE_{OPTION}**

Purpose: Define a curve [for example, load (ordinate value) versus time (abscissa value)], often loosely referred to as a load curve. The ordinate may represent something other than a load however, as in the case of curves for constitutive models.

In the case of constitutive models, *DEFINE_CURVE curves are rediscrretized internally with equal intervals along the abscissa for fast evaluation. Rediscrretization is *not* used when evaluating loading conditions such as pressures, concentrated forces, or displacement boundary conditions (see [Remark 1](#) for more details).

The curve rediscrretization algorithm was enhanced for the 2005 release of version 970. In certain cases the new load-curve routines changed the final results enough to disrupt benchmarks. For validated models, such as barriers and occupants, requiring numerical consistency, there are keyword options for reverting to the older algorithms.

Available options include:

<OPTION>

3858

5434a

which correspond to the first releases of version 970 and the 2005 release, respectively.

Since input errors and wrong results are sometimes related to load curve usage, a “*Load curve usage*” table is printed in the d3hsp file after all the input is read. This table should be checked to ensure that each curve ID is referenced by the option for which the curve is intended.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-----|-----|------|------|--------|-------|
| Variable | LCID | SIDR | SFA | SFO | OFFA | OFFO | DATTYP | LCINT |
| Type | I | I | F | F | F | F | I | I |
| Default | none | 0 | 1. | 1. | 0. | 0. | 0 | 0 |

Point Cards. Put one pair of points per card (2E20.0). Input is terminated at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|-------|---|---|---|---|---|
| Variable | A1 | | 01 | | | | | |
| Type | E20.0 | | E20.0 | | | | | |
| Default | 0.0 | | 0.0 | | | | | |

VARIABLE**DESCRIPTION**

| | |
|------|--|
| LCID | Load curve ID. Tables (see *DEFINE_TABLE) and load curves may not share common ID's. LS-DYNA allows load curve ID's and table ID's to be used interchangeably. A unique number has to be defined. |
| SIDR | Flag controlling use of curve during dynamic relaxation. SIDR set to 1 or 2 will activate a dynamic relaxation phase unless IDR-FLG = -999 in *CONTROL_DYNAMIC_RELAXATION. EQ.0: load curve used in normal analysis phase only or for other applications, EQ.1: load curve used in dynamic relaxation phase but not the normal analysis phase, EQ.2: load curve applies to both dynamic relaxation phase and normal analysis phase. |
| SFA | Scale factor for abscissa value. This is useful for simple modifications. EQ.0.0: default set to 1.0. |
| SFO | Scale factor for ordinate value (function). This is useful for simple modifications. EQ.0.0: default set to 1.0. |
| OFFA | Offset for abscissa values, see explanation below. |
| OFFO | Offset for ordinate values (function), see explanation below. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| DATYP | Data type. This affects how offsets are applied (see description below). EQ.-2: for fabric stress vs. strain curves (*MAT_FABRIC) as described below. EQ.0: general case for time dependent curves, force versus displacement curves and stress strain curves EQ.1: for general (x,y) data curves whose abscissa values do not increase monotonically EQ.6: for general (r,s) data (coordinates in a 2D parametric space) whose values do not increase monotonically. Use for definition of trimming polygons for trimmed NURBS (*ELEMENT_SHELL_NURBS_PATCH, NL.GT.0) |
| LCINT | The number of discretization points to use for this curve. If 0 is input, the value of LCINT from *CONTROL_SOLUTION will be used. |
| A1, A2, ... | Abscissa values. See remarks below. |
| O1, O2, ... | Ordinate (function) values. See remarks below. |

Remarks:

1. **Warning Concerning Rediscretization.** For constitutive models, LS-DYNA internally rediscretizes the curve with uniform spacing to bypass searching during evaluations. The major drawback of this algorithm is that any detail in the curve on a scale finer than the uniform rediscretization grid will be smoothed-out and lost. *It is, therefore, important to avoid placing a single point off at some value approaching infinity.* The lone point at infinity will cause the resolution of the uniform grid to be coarse relative to the other points, causing the rediscretized curve to be, possibly, featureless.

Therefore, when defining curves for constitutive models, points should be spaced as uniformly as possible. Also, since the constitutive model curves are extrapolated, it is important to ensure that extrapolation does not lead to physically meaningless values, such as a negative flow stress. Conversely, extrapolation can be exploited to control the results of evaluations at points far from the input data.

The number of points in each rediscretized curve is controlled by the parameter LCINT in *CONTROL_SOLUTION. By changing LCINT to a value greater than the default of 100, the rediscretized curves may better resemble the input curves. The data points of the rediscretized curves are written to messag and d3hsp if the parameter IPCURV is set to 1 in *CONTROL_OUTPUT.

2. **Scaling.** The load curve values are scaled after the offsets are applied, i.e.:
$$\text{Abscissa value} = \text{SFA} \times (\text{Defined value} + \text{OFFA})$$
$$\text{Ordinate value} = \text{SFO} \times (\text{Defined value} + \text{OFFO})$$
3. **DATTYP.** The DATTYP field controls how the curve is processed during the calculation.
 - a) For DATTYP = 0 positive offsets may be used when the abscissa represents time, since two additional points are generated automatically at time zero and at time $0.999 \times \text{OFFA}$ with the function values set to zero.
 - b) If DATTYP = 1, then the offsets do not create these additional points. Negative offsets for the abscissa simply shifts the abscissa values without creating additional points.
 - c) For *MAT_FABRIC material with FORM = 4, 14, -14, or 24, set DATYP = -2 to define stress vs. strain curves using engineering stress and strain rather than the 2nd Piola-Kirchhoff stress and Green strain.
4. **Context Dependent Extrapolation.** Load curves are not extrapolated by LS-DYNA for applied loads such as pressures, concentrated forces, displacement boundary conditions, etc. Function values are set to zero if the time, etc., goes off scale. Therefore, extreme care must be observed when defining load curves. In the constitutive models, extrapolation is employed if the values on the abscissa go off scale.
5. **Restart.** The curve offsets and scale factors are ignored during restarts if the curve is redefined. See *CHANGE_CURVE_DEFINITION in the restart section.

***DEFINE_CURVE_BOX_ADAPTIVITY**

Purpose: To define a polygon adaptive box for sheet metal forming. This keyword is applicable to shell elements. This keyword is used with *CONTROL_ADAPTIVE. This keyword is similar to *DEFINE_BOX_ADAPTIVE.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-------|-------|---|---|---|---|
| Variable | ID | PID | LEVEL | DIST1 | | | | |
| Type | I | I | I | F | | | | |
| Default | none | none | none | none | | | | |

Point Cards. Include as many as necessary. This input ends at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|------|---|------|---|---|---|
| Variable | X | | Y | | Z | | | |
| Type | F | | F | | F | | | |
| Default | none | | none | | none | | | |

VARIABLE**DESCRIPTION**

| | |
|-------|---|
| ID | Curve ID; must be unique. The curve must be closed: its first and last point <i>must</i> coincide. See Examples . |
| PID | Sheet blank Part ID, as in *PART. |
| LEVEL | Adaptive refinement levels, similar to the field MAXLVL in *CONTROL_ADAPTIVE. See Remark 1 . |

| VARIABLE | DESCRIPTION |
|----------|--|
| DIST1 | Depth in the Z-direction that the curve defined with Card 2 will be extruded. Currently this variable must be input as a negative value. The box depth in the Z-direction will be extended in the -Z-direction by $Z_{\min} - \text{DIST1} $ and in +Z-direction by $Z_{\max} + \text{DIST1} $, where Z_{\min} and Z_{\max} are the minimum and maximum Z coordinates in all the (X,Y,Z) data points input with Card 2. See Remark 3 and Figure 15-12 . |
| X | X coordinate of a point on the curve. See Remark 3 . |
| Y | Y coordinate of a point on the curve. See Remark 3 . |
| Z | Z coordinate of a point on the curve. See Remark 3 . |

Remarks:

1. **Mesh Refinement Definition.** Within the polygon, the variable LEVEL has priority over MAXLVL in *CONTROL_ADAPTIVE, but is limited by the minimum element size controlled by ADPSIZE. A larger LEVEL than MAXLVL value will enable more mesh refinement within the polygon, up to the size defined by ADPSIZE, than outside of the box. However, mesh refinement when LEVEL > MAXLVL is not recommended. This keyword (and *DEFINE_BOX_ADAPTIVE) is intended for the MAXLVL > LEVEL case in which the polygon box excludes the local areas of interest. For this case, refinement inside the local areas will be controlled by MAXLVL while outside of the area will be controlled by LEVEL as shown in [Figure 15-12](#).
2. **Advantages.** With this keyword only one box needs to be defined to specify the selected region while *DEFINE_ADAPTIVE_BOX requires multiple boxes to be defined for the same region as shown in [Figure 15-13](#).
3. **Curve Location.** The 3D curve (closed polygon) defined by (X,Y,Z) data pairs should be near the sheet blank after the blank is auto-positioned in the beginning of a simulation. Similar to *DEFINE_BOX_ADAPTIVE, only the elements on the sheet blank initially within the polygon will be considered for use with this keyword. Local coordinate system is not supported at the moment.
4. **IGES Format.** The 3D curve can be converted from IGES format to the format required here following the procedure outlined in keyword *INTERFACE_-BLANKSIZE.

Examples:

A partial keyword example is provided below, where inside the polygon mesh has no refinement (LEVEL = 1), while outside of the box the mesh is refined 5 levels (MAXLVL = 5). The final minimum element size is defined as 0.4. It is noted that the first point and last point of the polygon are the same, closing the polygon box.

Revision information:

This feature is available in SMP only, and in LS-DYNA Revision 81918 and later releases.

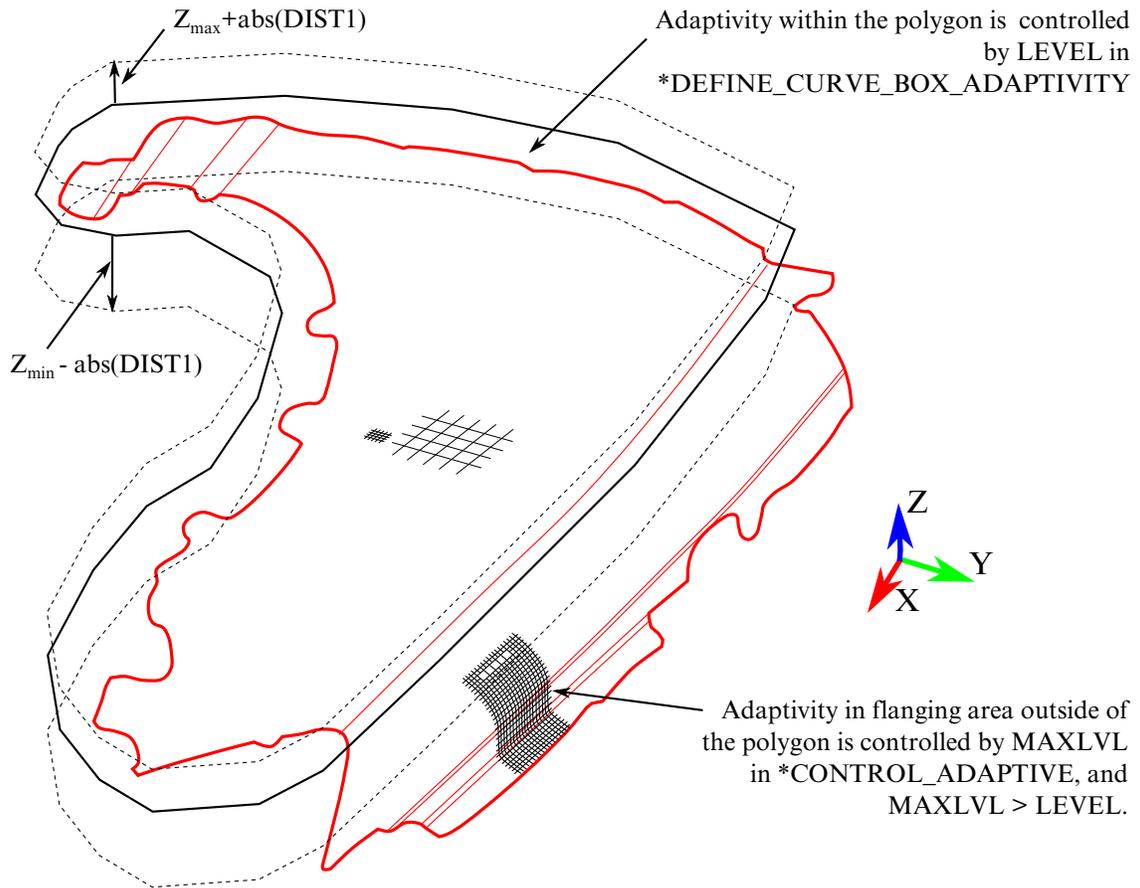

Figure 15-12. Defining an adaptive polygon box

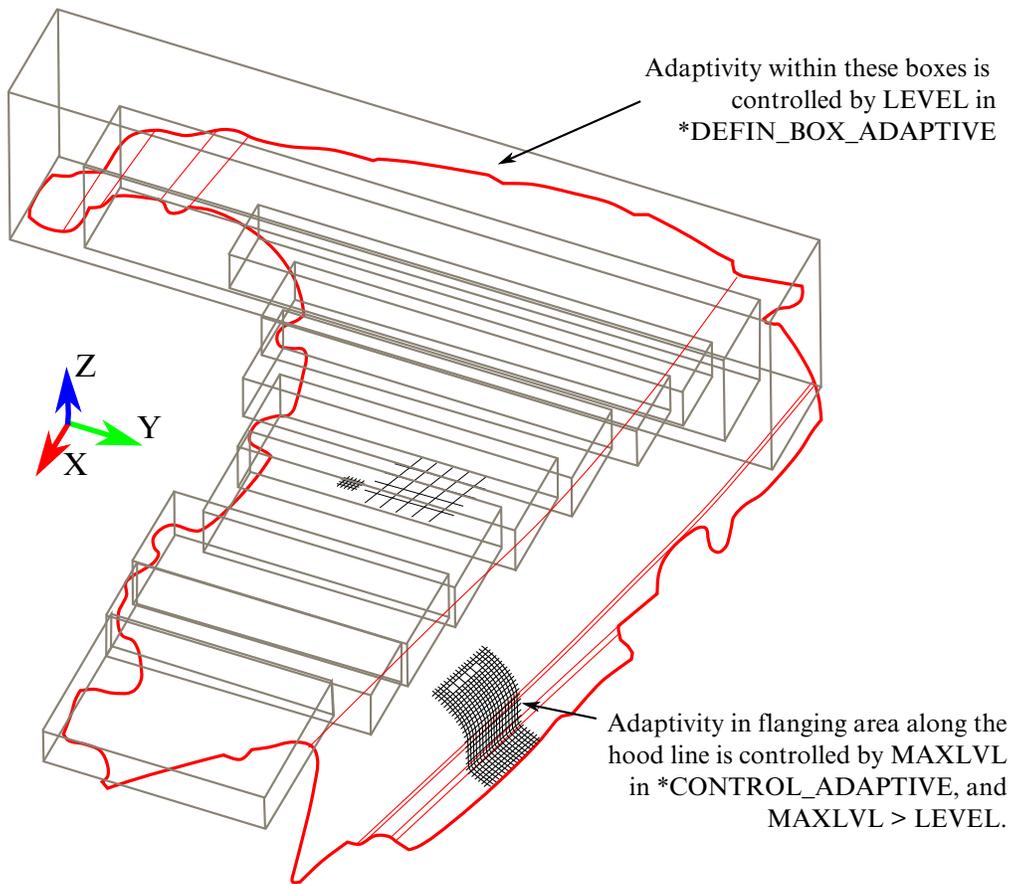

Figure 15-13. Defining adaptive boxes

***DEFINE_CURVE_COMPENSATION_CONSTRAINT_OPTION**

Purpose: This keyword with the two options allows for the definition of a localized die face region for springback compensation of stamping tools.

Options available include:

BEGIN

END

NOTE: *DEFINE_CURVE_COMPENSATION_CONSTRAINT_BEGIN and *DEFINE_CURVE_COMPENSATION_CONSTRAINT_END are not valid in the context of a general keyword input deck. Instead, they may only be used inside of an *INCLUDE_COMPENSATION_CURVE include file.

The required option, which must be either BEGIN or END, distinguishes between two different closed curves, which, when taken together identify a portion of the die wherein springback compensation is applied, and a transition region for which compensation smoothly tapers off.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|------|---|---|---|---|---|
| Variable | CRVID | INOUT | TYPE | | | | | |
| Type | I | I | I | | | | | |
| Default | none | 0 | none | | | | | |

Point Cards. Include as many cards as needed. This input ends at the next keyword ("**") card. Only the projection of this curve onto the *xy*-plane is used.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|---|-----|---|-----|---|---|---|
| Variable | X | | Y | | Z | | | |
| Type | F | | F | | F | | | |
| Default | 0.0 | | 0.0 | | 0.0 | | | |

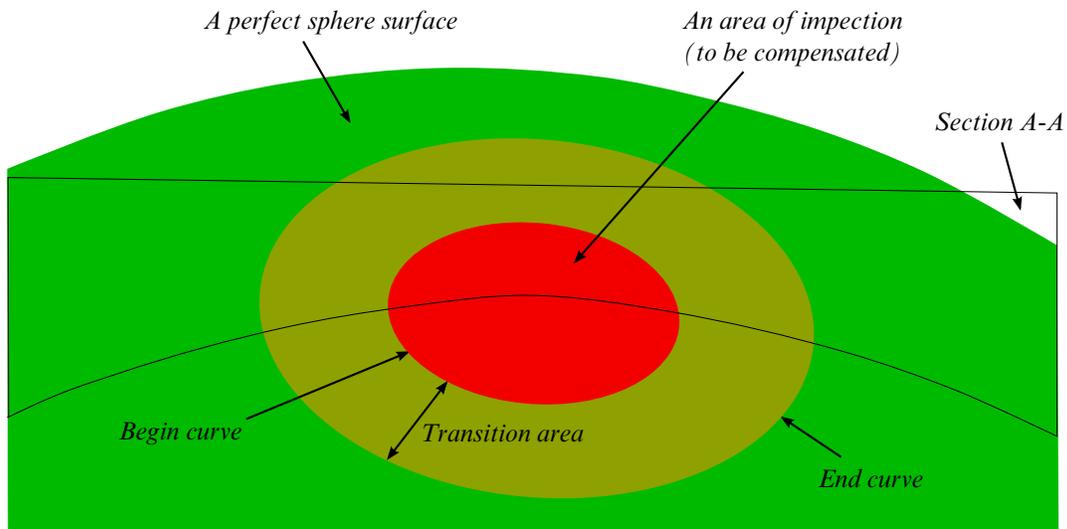

Figure 15-14. Local area compensation.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| CRVID | Curve ID; must be unique. The curve must be closed: its first and last point <i>must</i> coincide. |
| INOUT | Flag to indicate local area to be compensated: <p>EQ.0: For this option, the compensated region of the die consists of all points for which the projection onto the xy-plane is exterior to the projection of the BEGIN curve. The projection of the END curve is assumed exterior to the BEGIN curve. The transition region, then, consists of all die points for which the projection is between the BEGIN and END curves. All other points on the die are uncompensated.</p> <p>EQ.1: For this option, the compensated region of the die consists of all points for which the projection onto the xy-plane is interior to the projection of the BEGIN curve. The projection of the END curve is assumed exterior to the BEGIN curve. The transition region, then, consists of all die points for which the projection is between the BEGIN and END curves. All other points on the die are uncompensated. See Figure 15-14.</p> |
| TYPE | Type code - must be "0". |
| X | x -coordinate of a point on the curve. |
| Y | y -coordinate of a point on the curve. |

| VARIABLE | DESCRIPTION |
|-----------------|---------------------------------------|
| Z | z-coordinate of a point on the curve. |

Motivation:

Sometimes springback occurs in a localized region of the die face. Since other parts of the die face are better left undisturbed, a localized compensation makes the most sense to bring the part shape back to the design intent. A typical example will be the front portion along the grill and headlamp or the rear portion along the windshield of a trimmed hood inner panel. A decklid (or trunk lid) inner also exhibits similar needs. Once the localized areas are identified, iterative compensation scheme may be employed within this localized region to bring the springback panel back to design shape.

Modeling Details:

Referring to [Figure 15-14](#), the keywords `*COMPENSATION_CONSTRAINT_BEGIN` and `*COMPENSATION_CONSTRAINT_END` must be used together in a file, which in turn will be included in keyword `*INCLUDE_COMPENSATION_CURVE`. The keyword "BEGIN" precedes the keyword "END;" each is defined by discrete points. In addition, each curve must form a closed loop. The area formed between the two curves is a transition area and will be affected in the compensated tooling. Multiple disconnected curves can be joined together and output in the .xyz format required here using *Curve* → *Merge* → *Multiple Method* in LS-PrePost4.0 and later.

The curve can be a 3-D piecewise linear curve with coordinates in x , y and z . However, z -coordinates are ignored; meaning the tooling to be compensated must be positioned so the draw direction is in the global z -direction; otherwise an error will occur. In addition, it is assumed that both "blank before springback" and "blank after springback" will be smaller than rigid tools in dimension. Also, the rigid tool meshes should be discretized fine enough to provide enough degrees of freedom for the compensation.

Example – Single Region:

A complete input deck is provided below for a local compensation simulation. The keyword files `state1.k` and `state2.k` consist of model (nodes and elements) information for the blank before and after springback, respectively. If the blank is adaptively refined, the adaptive constraints must be included in the keyword files. The keyword file `tools.k` consists of the stamping tools (with PID 1, 2, 3 and 4) positioned in the home position. The keyword file `curvesxy.xyz` includes this keyword with both variations defining the two closed-loop curves used to define a localized area.

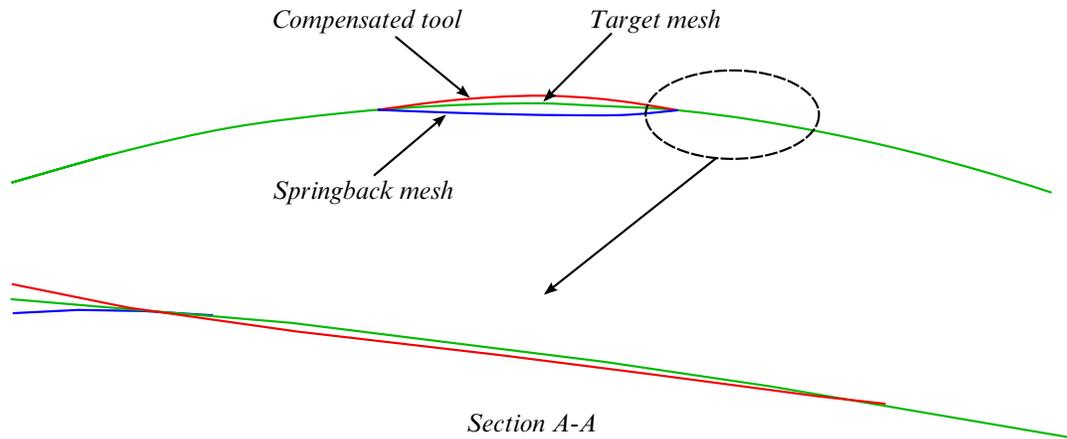

Figure 15-15. Local compensation details.

-4.07730e+02    1.61371e+03    -8.04858e+01
*END

```

It is noted the first point and last point are exactly the same, forming a closed loop. In Figure 15-14, local area compensation is to be performed in the center portion of a rigid sphere. Based on springback and target meshes, the compensated tool mesh is obtained, and smooth transition areas are achieved (see Figure 15-15). Here the compensation scale factor of 0.7 is used.

Example – Multiple Regions:

Multi-region localized compensation is also possible by defining multiple pairs of the BEGIN and END versions of this keyword, each forming a localized region. For example, for localized compensation of two regions, the file curvesxy.xyz will read as follows,

```

*KEYWORD
*DEFINE_CURVE_COMPENSATION_CONSTRAINT_BEGIN
$   CID   IN/OUT   TYPE

```

Figure 15-16 (top) shows an example of two localized areas of the sphere to be compensated. The compensation results are shown in Figure 15-16 (bottom). Again, a compensation scale factor of 0.7 was used and smooth transition areas are achieved.

Revision Information:

This feature is available in double precision version of LS-DYNA starting in Revision 62038. Multi-region localized compensation is available starting in Revision 66129 and later releases. In addition, prior to Revision 66129, all keywords must be capitalized. Also, official release version starting in R7.1.1 (double precision) can be used.

***DEFINE_CURVE_DRAWBEAD**

Purpose: This keyword simplifies the definition of a draw bead, which previously required the use of many keywords.

NOTE: This option has been deprecated in favor of *DEFINE_MULTI_DRAWBEADS_IGES.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|------|------|-------|-------|------|---|
| Variable | CID | TCTYPE | VID | PID | BLKID | PERCT | LCID | |

| Default | none | none | none | none | none | 0.0 | none | |

Point Cards. For TCTYPE = 1 define points on the curve. Input is terminated at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|----|---|---|---|---|---|
| Variable | CX | CY | CZ | | | | | |
| Type | F | F | | | | | | |
| Default | 0.0 | 0.0 | | | | | | |

IGES Card. For TCTYPE = 2 set an IGES file.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|---|---|---|---|---|---|---|
| Variable | FILENAME | | | | | | | |
| Type | C | | | | | | | |
| Default | none | | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| CID | Draw bead curve ID; must be unique. |
| TCTYPE | Flag to indicate input curve data format: EQ.1: XYZ data, EQ.2: IGES format data. |
| VID | Vector ID, as defined by *DEFINE_VECTOR. This vector is used to project the supplied curves to the rigid tool, defined by the PID below. |
| PID | Part ID of a rigid tool to which the curves are projected and attached. |
| BLKID | Part ID of the blank. |
| PERCT | Draw bead lock percentage or draw bead force. GT.0: Percentage of the full lock force for the bead defined. This is the ratio of desired restraining force over the full lock force. The value should be between 0.0 and 100.0. LT.0: Absolute value is the draw bead force. |
| LCID | Load curve ID defining material hardening curve of the sheet blank, BLKID. |
| CX, CY, CZ | Points on the curve. |
| FILENAME | IGES file name. |

Remarks:

1. This feature implements the following input algorithm for drawbeads:
 - a) It reads a draw bead curve in either XYZ or IGES format
 - b) projects the curve to the rigid tool specified
 - c) creates extra node set and attaches it to the rigid tool.
 - d) With supplied material hardening curve (LCID), full lock force is calculated.

There is no need to define *CONTACT_DRAWBEAD and *CONSTRAINED_RIGID_BODIES since they are treated internally within the code.

2. The “curve” menu in LS-PrePost can be used to break or join multiple disconnected curves, and output in either ‘XYZ’ or IGES format.
3. The following partial keyword example defines a draw bead curve ID 98 (IGES file “bead1.iges”) to restrain blank part ID 63. Full lock force is calculated from the strain hardening curve ID 400. The draw bead is projected along vector ID 991, and is attached to a rigid tool of part ID 3.

Revision information:

This feature is available starting in LS-DYNA R5 Revision 62464.

*DEFINE

*DEFINE_CURVE_DUPLICATE

*DEFINE_CURVE_DUPLICATE

Purpose: Define a curve by optionally scaling and offsetting the abscissa and ordinates of another curve defined by the *DEFINE_CURVE keyword.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|-----|-----|------|------|---|---|
| Variable | LCID | RLCID | SFA | SFO | OFFA | OFFO | | |
| Type | I | I | F | F | F | F | | |
| Default | none | none | 1. | 1. | 0. | 0. | | |

VARIABLE

DESCRIPTION

| | |
|-------|--|
| LCID | Load curve ID. Tables (see *DEFINE_TABLE) and load curve ID's must be unique. |
| RLCID | Reference load curve ID. |
| SFA | Scale factor for abscissa value of curve ID, RLCID. This value scales the SFA value defined for RLCID. EQ.0.0: default set to 1.0. |
| SFO | Scale factor for ordinate value (function) of curve ID, RLCID. This value scales the SFO value defined for RLCID. EQ.0.0: default set to 1.0. |
| OFFA | Offset for abscissa values. This value is added to the OFFA value defined for RLCID. |
| OFFO | Offset for ordinate values (function). This value is added to the OFFO value defined for RLCID. |

***DEFINE_CURVE_ENTITY**

Purpose: Define a curve of straight line segments and circular arcs that defines an axisymmetric surface. This curve can only be used with the keyword *CONTACT_ENTITY for the load curve entity GEOTYP = 11.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|-----|-----|------|------|------|---|
| Variable | LCID | SFA | SFO | SFR | OFFA | OFFO | OFFR | |
| Type | I | F | F | F | F | F | F | |
| Default | none | 1. | 1. | 1. | 0. | 0. | 0. | |

Point Cards. Put one point per card. Include as many cards as needed. This input terminates at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|-------|---|----------|---|-------|---|
| Variable | A_i | | O_i | | R_i | | IFLAG | |
| Type | F | | F | | F | | I | |
| Default | 0.0 | | 0.0 | | optional | | ↓ | |

VARIABLE**DESCRIPTION**

| | |
|------|--|
| LCID | Load curve ID. Tables (see *DEFINE_TABLE) and load curves may not share common IDs. LS-DYNA allows load curve IDs and table IDs to be used interchangeably. A unique number has to be defined. |
| SFA | Scale factor for axis value. This is useful for simple modifications. EQ.0.0: default set to 1.0. |
| SFO | Scale factor for radius values. This is useful for simple modifications. EQ.0.0: default set to 1.0. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| SFR | Scale factor for circular radius. This is useful for simple modifications. EQ.0.0: default set to 1.0. |
| OFFA | Offset for axis values. See Remark 1 . |
| OFFO | Offset for radius values. See Remark 1 . |
| OFFR | Offset for circular radius. See Remark 1 . |
| A_i | Z-axis coordinates along the axis of rotation. |
| O_i | Radial coordinates from the axis of rotation |
| R_i | Radius of arc between points (A_i, O_i) and (A_{i+1}, O_{i+1}) . If zero, a straight line segment is assumed. |
| IFLAG | Defined if $ R_i > 0.0$. Set to 1.0 if the center of the arc is inside the axisymmetric surface and to -1.0 if the center is outside the axisymmetric surface. |

Remarks:

1. **Scaling.** The load curve values are scaled after the offsets are applied, that is:

$$\begin{aligned}\text{Axis value} &= \text{SFA} \times (\text{Defined value} + \text{OFFA}) \\ \text{Radius value} &= \text{SFO} \times (\text{Defined value} + \text{OFFO}) \\ \text{Circular value} &= \text{SFR} \times (\text{Defined value} + \text{OFFR})\end{aligned}$$

*DEFINE_CURVE_FEEDBACK

Purpose: Define information that is used as the solution evolves to scale the ordinate values of the specified load curve ID. This keyword is usually used in connection with sheet metal forming calculations.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-------|-------|---|---|---|---|
| Variable | LCID | PID | BOXID | FLDID | | | | |
| Type | I | I | I | I | | | | |
| Default | none | none | 0 | none | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-----|-----|------|---|---|---|
| Variable | FSL | TSL | SFF | SFT | BIAS | | | |
| Type | F | F | F | F | F | | | |
| Default | none | none | 1.0 | 1.0 | 0.0 | | | |

VARIABLE**DESCRIPTION**

| | |
|-------|---|
| LCID | ID number for load curve to be scaled. |
| PID | Active part ID for load curve control |
| BOXID | Box ID. Elements of specified part ID contained in box are checked. If the box ID is set to zero the all elements of the active part are checked. |
| FLDID | Load curve ID which defines the flow limit diagram as shown in Figure 15-17 . |
| FSL | If the ratio, $r = \epsilon_{\text{major_workpiece}} / \epsilon_{\text{major_fld}}$ exceeds FSL, then scale factor for flow, SFF, is active. |
| TSL | Thickness strain limit. If the thickness strain limit is exceeded, then the scale factor for thickening, SFT, is active. |

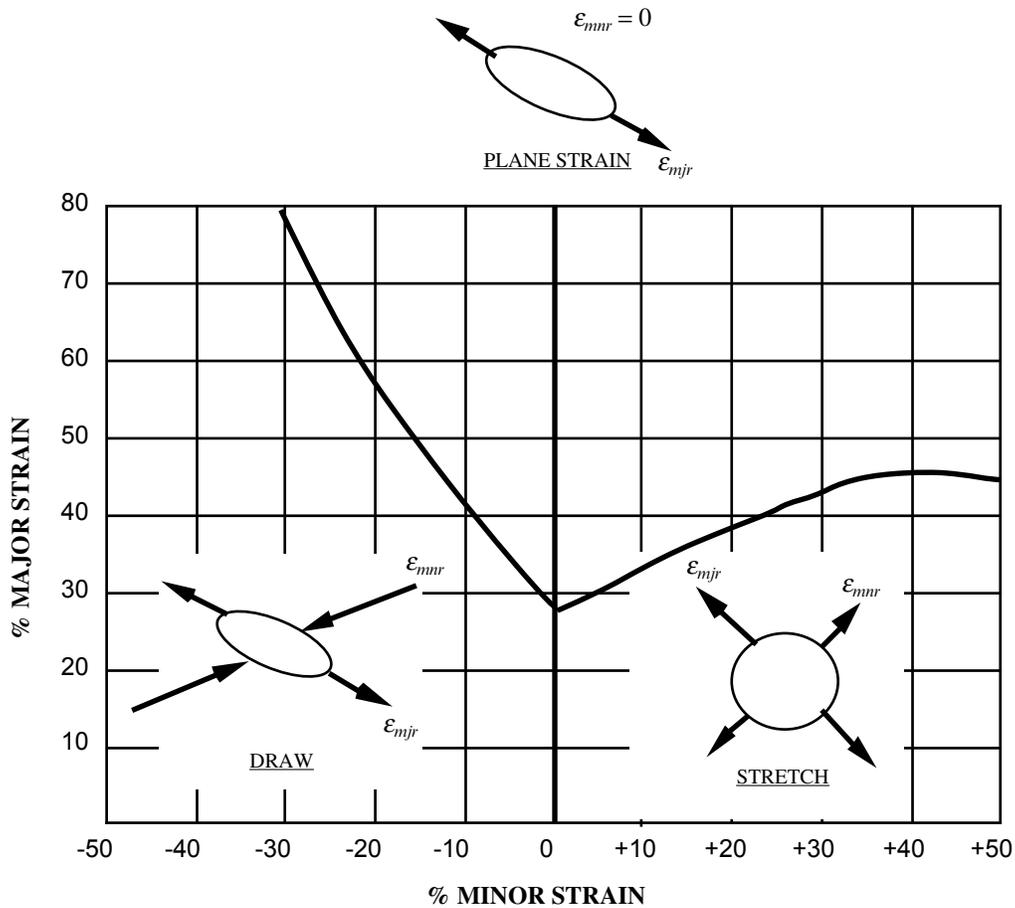

Figure 15-17. Flow limit diagram.

| VARIABLE | DESCRIPTION |
|----------|---|
| SFF | Scale factor for the flow limit diagram. |
| SFT | Scale factor for thickening. |
| BIAS | Bias for combined flow and thickening. Bias must be between -1 and 1. |

Remarks:

This feature scales the ordinate values of a load curve according to a computed scale factor, S_f , that depends on both the major strain, r , and the through thickness, t . At each time step the load curve is scaled by S_f according to,

$$S_{\text{scaled load curve}}^{n+1} = S_f(r, t) \times S_{\text{load curve}}^n$$

where the superscript denotes the time step. The scale factor depends on r , which is a strain measure defined as,

$$r = \frac{\varepsilon_{\text{major}_{\text{workpiece}}}}{\varepsilon_{\text{major}_{\text{fld}}}}$$

The scale factor, then, is given by,

$$S_f = \begin{cases} 1 & r < \text{FSL}, t < \text{TSL} \\ \text{SFF} & r > \text{FSL}, t < \text{TSL} \\ \text{SFT} & r < \text{FSL}, t > \text{TSL} \\ \frac{1}{2}(1 - \text{BIAS}) \times \text{SFF} + \frac{1}{2}(1 + \text{BIAS}) \times \text{SFT} & r > \text{FSL}, t > \text{TSL} \end{cases}$$

Usually SFF is slightly less than unity and SFT is slightly greater than unity so that $S_{\text{load curve}}$ changes insignificantly from time step to time step.

***DEFINE_CURVE_FLC**

Purpose: This keyword allows for defining the Forming Limit Diagram (FLD) using sheet metal thickness t and strain hardening value n . This keyword is applicable to shell elements only.

This feature is available in LS-DYNA Revision 61435 and later releases.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|-----|---|---|---|---|---|
| Variable | LCID | TH | TN | | | | | |
| Type | I | F | F | | | | | |
| Default | none | 0.0 | 0.0 | | | | | |

VARIABLE**DESCRIPTION**

| | |
|------|---|
| LCID | Load curve ID. |
| TH | Sheet metal thickness. |
| TN | Strain hardening value of the sheet metal, as in power law (Swift). |

Remarks:

1. **Related Keywords.** This keyword is used in conjunction with keyword *MAT_TRANSVERSELY_ANISOTROPIC_ELASTIC_PLASTIC_NLP_FAILURE and is for shell elements only. For detailed formula of calculating the FLD based on sheet metal thickness and n -value, please refer to the following paper: *Ming F. Shi, Shawn Gelisse, "Issues on the AHSS Forming Limit Determination", IDDRG 2006.*
2. **Material and Geometric Restrictions.** It is noted that this FLD calculation method is limited to sheet metal steels with thickness equal to or less than 2.5 mm, and it is not suitable for aluminum sheets. For aluminum sheets, *DEFINE_CURVE can be used to input the FLC for the field ICFLD in *MAT_TRANSVERSELY_ANISOTROPIC_ELASTIC_PLASTIC_NLP_FAILURE.

Example:

In a validation example shown in [Figure 15-18](#), a single shell element is stretched in three typical strain paths (linear): uniaxial, plane strain and equi-biaxial. Strain limits

for each path are recovered when the history variable (Formability Index limit in *MAT_037) reaches 1.0, shown in Figure 15-19. The top most point (strain limit) of each strain path coincides with the FLC curve calculated according to the paper, indicating the FLC defined by this keyword is working correctly. As shown in a partial keyword file below, the FLC is defined using a thickness value of 1.5 and n -value of 0.159. The LCID of 891 is used in keyword *MAT_TRANSVERSELY_ANISOTROPIC_ELASTIC_PLASTIC_NLP_FAILURE.

***DEFINE_CURVE_FLD_FROM_TRIAXIAL_LIMIT**

Purpose: This keyword creates a forming limit diagram (FLD) curve from a given stress triaxial limit curve, which can be referred to by material models utilizing a FLD curve, such as *MAT_037_NLP_FAILURE or *MAT_260B). The conversion assumes plane stress and Von-Mises yield criterion. The converted FLD curve can be found in the ".o" file (a scratch file from batch queue run). Another related keyword is: *DEFINE_CURVE_TRIAXIAL_LIMIT_FROM_FLD.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | LCID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

Point Cards. Put one pair of points per card (2E20.0). Input is terminated at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|-------|---|---|---|---|---|
| Variable | A1 | | O1 | | | | | |
| Type | E20.0 | | E20.0 | | | | | |
| Default | 0.0 | | 0.0 | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| LCID | The FLD curve ID to be created. |
| A1, A2, ... | Abscissas represent stress triaxialities, typically ranging from -1/3 to 2/3. |
| O1, O2, ... | Ordinates represent equivalent plastic strains to fracture. |

Remarks:

1. In an example of the keyword shown below, the input stress triaxial limit curve is obtained from *Li, Yaning et al, "Prediction of shear-induced fracture in sheet metal forming," Journals of Material Processing Technology, Volume 210, issue 14, (2010)*. Using a uniaxial tension model on a single element, calculated FLD from LS-DYNA is shown in [Figure 15-20](#), which matches the FLD from the paper.

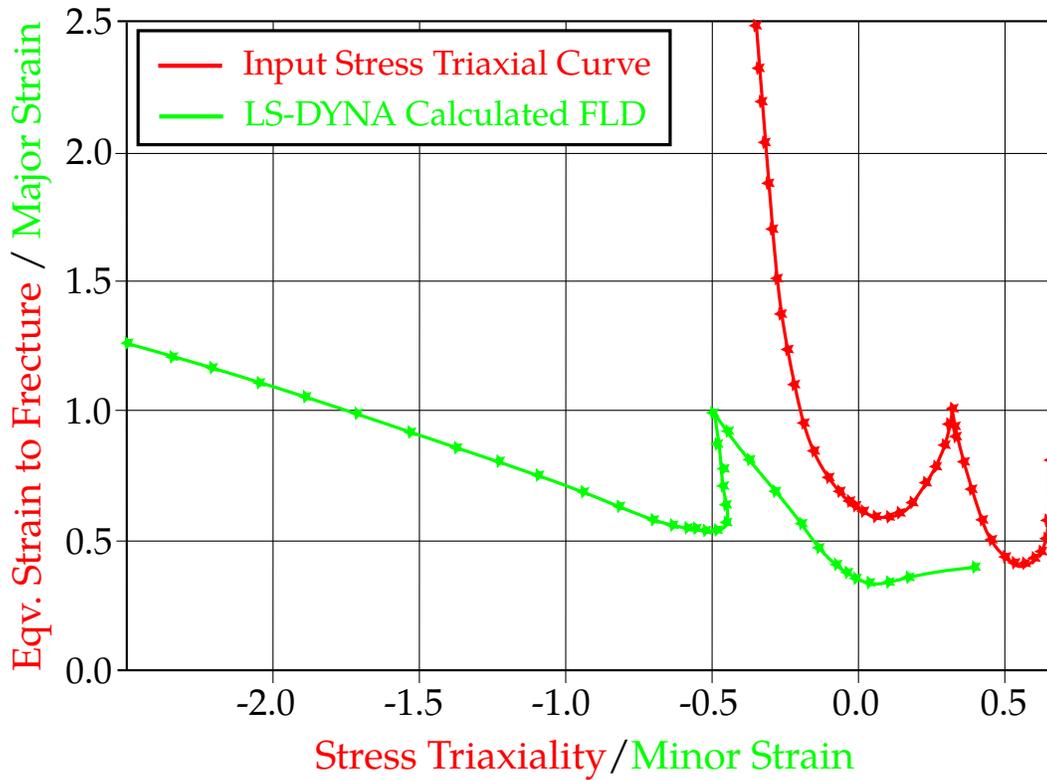

Figure 15-20. LS-DYNA calculated FLD from input stress triaxial curve. Reference: Li, Yaning et al, "Prediction of shear-induced fracture in sheet metal forming," *Journals of Material Processing Technology*, Volume 210, issue 14, (2010).

Revision Information:

This feature is available starting from Revision 116631.

***DEFINE_CURVE_FUNCTION**

Purpose: Define a curve [for example, load (ordinate value) versus time (abscissa value)] where the ordinate is given by a function expression. The function can reference other curve definitions, kinematical quantities, forces, interpolating polynomials, intrinsic functions, and combinations thereof. Please note that many functions require the definition of a local coordinate system (see [Remark 1](#) below). To output the curve to an ASCII database, see *DATABASE_CURVOUT. This command is not for defining curves for material models. Note that arguments appearing in square brackets “[]” are optional.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|---|---|---|---|---|---|

VARIABLE**DESCRIPTION**

| | |
|------|---|
| LCID | Load curve ID. Tables (see *DEFINE_TABLE) and load curves may not share common ID's. LS-DYNA allows load curve ID's and table ID's to be used interchangeably. A unique number has to be defined. |
| SIDR | Stress initialization by dynamic relaxation: EQ.0: load curve used in transient analysis only or for other applications, |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | EQ.1: load curve used in stress initialization but not transient analysis, |
| | EQ.2: load curve applies to both initialization and transient analysis. |
| FUNCTION | Arithmetic expression involving a combination of the following possibilities. |

Constants and Variables:

| FUNCTION | DESCRIPTION |
|-----------------|---|
| TIME | Current simulation time |
| TIMESTEP | Current simulation time step |
| PI | Proportionality constant relating the circumference of a circle to its diameter |
| DTOR | Degrees to radians conversion factor ($\pi/180$) |
| RTOD | Radians to degrees conversion factor ($180/\pi$) |

Intrinsic Functions:

| FUNCTION | DESCRIPTION |
|--------------------|--|
| ABS(a) | Absolute value of a |
| AINT(a) | Nearest integer whose magnitude is not larger than a |
| ANINT(a) | Nearest whole number to a |
| MOD(a_1, a_2) | Remainder when a_1 is divided by a_2 |
| SIGN(a_1, a_2) | Transfer sign of a_2 to magnitude of a_1 |
| MAX(a_1, a_2) | Maximum of a_1 and a_2 |
| MIN(a_1, a_2) | Minimum of a_1 and a_2 |
| SQRT(a) | Square root of a |
| EXP(a) | e raised to the power of a |

| FUNCTION | DESCRIPTION |
|--|--|
| LOG(<i>a</i>) | Natural logarithm of <i>a</i> |
| LOG10(<i>a</i>) | Log base 10 of <i>a</i> |
| SIN(<i>a</i>) | Sine of <i>a</i> |
| COS(<i>a</i>) | Cosine of <i>a</i> |
| TAN(<i>a</i>) | Tangent of <i>a</i> |
| ASIN(<i>a</i>) | Arc sine of <i>a</i> |
| ACOS(<i>a</i>) | Arc cosine of <i>a</i> |
| ATAN(<i>a</i>) | Arc tangent of <i>a</i> |
| ATAN2(<i>a</i> ₁ , <i>a</i> ₂) | Arc tangent of <i>a</i> ₁ / <i>a</i> ₂ |
| SINH(<i>a</i>) | Hyperbolic sine of <i>a</i> |
| COSH(<i>a</i>) | Hyperbolic cosine of <i>a</i> |
| TANH(<i>a</i>) | Hyperbolic tangent of <i>a</i> |

Load Curves:

| FUNCTION | DESCRIPTION |
|---|---|
| LC <i>n</i> | Ordinate value of curve <i>n</i> defined elsewhere (see *DEFINE_CURVE) |
| DELAY(LC <i>n</i> , <i>t</i> _{delay} , <i>y</i> _{def}) | <p>Delays curve <i>n</i>, defined by *DEFINE_CURVE_FUNCTION, *DEFINE_FUNCTION or DEFINE_CURVE, by <i>t</i>_{delay} when simulation time ≥ <i>t</i>_{delay}, and sets the delayed curve value to <i>y</i>_{def} when time < <i>t</i>_{delay}, that is,</p> $f_{\text{delay}}(t) = \begin{cases} f(t - t_{\text{delay}}) & t \geq t_{\text{delay}} \\ y_{\text{def}} & t < t_{\text{delay}} \end{cases}$ <p>For a nonlinear curve, a <i>t</i>_{delay} equal to more than 5,000 time steps might compromise the accuracy and must be used with caution.</p> <p>When <i>t</i>_{delay} is a negative integer, delay time is input in terms of time step; <i>t</i>_{delay} is the number of delay time steps. In this case, <i>t</i>_{delay} is limited to a maximum of 100.</p> |

| FUNCTION | DESCRIPTION |
|-----------------|--|
| | For example, $t_{\text{delay}} = -2$ delays the curve by 2 time steps. |

Coordinate Functions:

| FUNCTION | DESCRIPTION |
|-----------------|---|
| $CX(n)$ | Value of x -coordinate for node n . |
| $CY(n)$ | Value of y -coordinate for node n . |
| $CZ(n)$ | Value of z -coordinate for node n . |

Displacement Functions:

| FUNCTION | DESCRIPTION |
|---------------------|---|
| $DM(n_1[,n_2])$ | Magnitude of translational displacement of node n_1 relative to node n_2 . Node n_2 is optional and if omitted, the displacement is computed relative to ground. |
| $DMRB(n)$ | Magnitude of translational displacement of rigid body having a part ID of n |
| $DX(n_1[,n_2,n_3])$ | x -translational displacement of node n_1 relative to node n_2 expressed in the local coordinate system of node n_3 . In other words, at any time t , the function returns the component of relative displacement that lies in the x -direction of the local coordinate system at time t . If node n_2 is omitted, it defaults to ground. If node n_3 is not specified, the displacement is reported in the global coordinate system. |
| $DY(n_1[,n_2,n_3])$ | y -translational displacement of node n_1 relative to node n_2 expressed in the local coordinate system of node n_3 . In other words, at any time t , the function returns the component of relative displacement that lies in the y -direction of the local coordinate system at time t . If node n_2 is omitted it defaults to ground. If node n_3 is not specified, the displacement is reported in the global coordinate system. |

| FUNCTION | DESCRIPTION |
|-----------------------|---|
| DZ($n_1[,n_2,n_3]$) | z -translational displacement of node n_1 relative to node n_2 expressed in the local coordinate system of node n_3 . In other words, at any time t , the function returns the component of relative displacement that lies in the z -direction of the local coordinate system at time t . If node n_2 is omitted, it defaults to ground. If node n_3 is not specified, the displacement is reported in the global coordinate system. |
| DXRB(n) | x -translational displacement of rigid body having a part ID of n |
| DYRB(n) | y -translational displacement of rigid body having a part ID of n |
| DZRB(n) | z -translational displacement of rigid body having a part ID of n |
| AX($n_1[,n_2]$) | Rotation displacement of node n_1 about the local x -axis of node n_2 . If n_2 is not specified, then it defaults to ground. In computing this value it is assumed that the rotation about the other two axes (y -, z -axes) of node n_2 is zero. See Remark 1 . |
| AY($n_1[,n_2]$) | Rotation displacement of node n_1 about the local y -axis of node n_2 . If n_2 is not specified, then it defaults to ground. In computing this value it is assumed that the rotation about the other two axes (x -, z -axes) of node n_2 is zero. See Remark 1 . |
| AZ($n_1[,n_2]$) | Rotation displacement of node n_1 about the local z -axis of node n_2 . If n_2 is not specified, then it defaults to ground. In computing this value it is assumed that the rotation about the other two axes (x -, y -axes) of node n_2 is zero. See Remark 1 . |
| PSI($n_1[,n_2]$) | First angle in the body2:313 Euler rotation sequence which orients node n_1 in the frame of node n_2 . If n_2 is omitted, it defaults to ground. See Remark 1 . |
| THETA($n_1[,n_2]$) | Second angle in the body2:313 Euler rotation sequence which orients node n_1 in the frame of node n_2 . If n_2 is omitted, it defaults to ground. See Remark 1 . |
| PHI($n_1[,n_2]$) | Third angle in the body2:313 Euler rotation sequence which orients node n_1 in the frame of node n_2 . If n_2 is omitted, it defaults to ground. See Remark 1 . |
| YAW($n_1[,n_2]$) | First angle in the body3:321 yaw-pitch-roll rotation sequence which orients node n_1 in the frame of node n_2 . If n_2 is omitted, it defaults to ground. See Remark 1 . |

| FUNCTION | DESCRIPTION |
|--------------------------|---|
| PITCH(n_1 [, n_2]) | Second angle in the body3:321 yaw-pitch-roll rotation sequence which orients node n_1 in the frame of node n_2 . If n_2 is omitted, it defaults to ground. See Remark 1 . |
| ROLL(n_1 [, n_2]) | Third angle in the body3:321 yaw-pitch-roll rotation sequence which orients node n_1 in the frame of node n_2 . If n_2 is omitted, it defaults to ground. See Remark 1 . |

Velocity Functions:

| FUNCTION | DESCRIPTION |
|-------------------------------|--|
| VM(n_1 [, n_2]) | Magnitude of translational velocity of node n_1 relative to node n_2 . Node n_2 is optional and if omitted the velocity is computed relative to ground. |
| VR(n_1 [, n_2]) | Relative radial translational velocity of node n_1 relative to node. If node n_2 is omitted, it defaults to ground. |
| VX(n_1 [, n_2 , n_3]) | x -component of the difference between the translational velocity vectors of node n_1 and node n_2 in the local coordinate system of node n_3 . If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. |
| VY(n_1 [, n_2 , n_3]) | y -component of the difference between the translational velocity vectors of node n_1 and node n_2 in the local coordinate system of node n_3 . If node n_2 is omitted it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. |
| VZ(n_1 [, n_2 , n_3]) | z -component of the difference between the translational velocity vectors of node n_1 and node n_2 in the local coordinate system of node n_3 . If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. |
| WM(n_1 [, n_2]) | Magnitude of angular velocity of node n_1 relative to node n_2 . Node n_2 is optional and if omitted the angular velocity is computed relative to ground. |

| FUNCTION | DESCRIPTION |
|---------------------|---|
| $WX(n_1[,n_2,n_3])$ | x -component of the difference between the angular velocity vectors of node n_1 and node n_2 in the local coordinate system of node n_3 . If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. See Remark 1 . |
| $WY(n_1[,n_2,n_3])$ | y -component of the difference between the angular velocity vectors of node n_1 and node n_2 in the local coordinate system of node n_3 . If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. See Remark 1 . |
| $WZ(n_1[,n_2,n_3])$ | z -component of the difference between the angular velocity vectors of node n_1 and node n_2 in the local coordinate system of node n_3 . If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. See Remark 1 . |

Acceleration Functions:

| FUNCTION | DESCRIPTION |
|-----------------------|---|
| $ACCM(n_1[,n_2])$ | Magnitude of translational acceleration of node n_1 relative to node n_2 . Node n_2 is optional and if omitted the acceleration is computed relative to ground. See Remark 1 . |
| $ACCX(n_1[,n_2,n_3])$ | x -component of the difference between the translational acceleration vectors of node n_1 and node n_2 in the local coordinate system of node n_3 . If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. See Remark 1 . |
| $ACCY(n_1[,n_2,n_3])$ | y -component of the difference between the translational acceleration vectors of node n_1 and node n_2 in the local coordinate system of node n_3 . If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. See Remark 1 . |
| $ACCZ(n_1[,n_2,n_3])$ | z -component of the difference between the translational acceleration vectors of node n_1 and node n_2 in the local coordinate system of node n_3 . If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. See Remark 1 . |

| FUNCTION | DESCRIPTION |
|-------------------------|---|
| WDTM($n_1[,n_2]$) | Magnitude of angular acceleration of node n_1 relative to node n_2 . Node n_2 is optional and if omitted the angular acceleration is computed relative to ground. See Remark 1 . |
| WDTX($n_1[,n_2,n_3]$) | x -component of the difference between the angular acceleration vectors of node n_1 and node n_2 in the local coordinate system of node n_3 . If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. See Remark 1 . |
| WDTY($n_1[,n_2,n_3]$) | y -component of the difference between the angular acceleration vectors of node n_1 and node n_2 in the local coordinate system of node n_3 . If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. See Remark 1 . |
| WDTZ($n_1[,n_2,n_3]$) | z -component of the difference between the angular acceleration vectors of node n_1 and node n_2 in the local coordinate system of node n_3 . If node n_2 is omitted, it defaults to ground. Node n_3 is optional and if not specified the global coordinate system is used. See Remark 1 . |

Generic Force Functions:

| FUNCTION | DESCRIPTION |
|-----------------------|--|
| FM($n_1[,n_2]$) | Magnitude of the SPC force acting on node n_1 minus the force acting on node n_2 . Node n_2 is optional; if omitted the force acting only on n_1 is returned. See Remark 1 . |
| FX($n_1[,n_2,n_3]$) | x -component of SPC force acting on node n_1 as computed in the optional local system of node n_3 . If n_2 is specified, the force acting on n_2 is subtracted from the force acting on n_1 . See Remark 1 . |
| FY($n_1[,n_2,n_3]$) | y -component of SPC force acting on node n_1 as computed in the optional local system of node n_3 . If n_2 is specified, the force acting on n_2 is subtracted from the force acting on n_1 . See Remark 1 . |
| FZ($n_1[,n_2,n_3]$) | z -component of SPC force acting on node n_1 as computed in the optional local system of node n_3 . If n_2 is specified, the force acting on n_2 is subtracted from the force acting on n_1 . See Remark 1 . |

| FUNCTION | DESCRIPTION |
|-------------------------------|---|
| TM(n_1 [, n_2]) | Magnitude of SPC torque acting on node n_1 minus the torque acting node n_2 . Node n_2 is optional; if omitted the torque acting only on n_1 is returned. See Remark 1 . |
| TX(n_1 [, n_2 , n_3]) | x -component of the SPC torque acting on node n_1 as computed in the optional local system of node n_3 . If n_2 is specified, the torque acting on n_2 is subtracted from the torque acting on n_1 . See Remark 1 . |
| TY(n_1 [, n_2 , n_3]) | y -component of the SPC torque acting on node n_1 as computed in the optional local system of node n_3 . If n_2 is specified, the torque acting on n_2 is subtracted from the torque acting on n_1 . See Remark 1 . |
| TZ(n_1 [, n_2 , n_3]) | z -component of the SPC torque acting on node n_1 as computed in the optional local system of node n_3 . If n_2 is specified, the torque acting on n_2 is subtracted from the torque acting on n_1 . See Remark 1 . |

Sensor Functions:

| FUNCTION | DESCRIPTION |
|--------------------------|---|
| SENSOR(n) | Returns a value of 1.0 if *SENSOR_CONTROL of control ID n has a status of "on". If the sensor has a status of "off", then the returned value is equal to the value of the TYPEID field on *SENSOR_CONTROL when the TYPE field is set to "function", otherwise SENSOR(n) returns zero. |
| SENSORD(n , $idflt$) | Returns the current value of *SENSOR_DEFINE sensor having ID n . $idflt$ is the optional filter ID defined using *DEFINE_FILTER. |

Contact Force Functions:

| FUNCTION | DESCRIPTION |
|-------------------------------------|---|
| <i>RCFORC(id, ims, comp, local)</i> | <p>Returns the component <i>comp</i> (see description below) of contact interface <i>id</i> (see *CONTACT_..._ID) as calculated in the local coordinate system <i>local</i> (see *DEFINE_COORDINATE_...). If <i>local</i> equals zero, then forces are reported in the global coordinate system. Forces are reported for the slave side when <i>ims</i> = 1 or master side when <i>ims</i> = 2.</p> <p>The admissible values of <i>comp</i> and their corresponding force component are as follows:</p> <ul style="list-style-type: none"> comp.EQ.1: <i>x</i> force component comp.EQ.2: <i>y</i> force component comp.EQ.3: <i>z</i> force component comp.EQ.4: resultant force |

Element Specific Functions:

| FUNCTION | DESCRIPTION |
|----------------------------------|---|
| <i>BEAM(id, jflag, comp, rm)</i> | <p>Returns the force component <i>comp</i> (see description below) of beam <i>id</i> as calculated in the local coordinate system <i>rm</i>. Forces are reported in the global coordinate system if <i>rm</i> is zero. If <i>rm</i> equals -1 the beam's <i>r</i>, <i>s</i>, and <i>t</i> force/moment is returned. If <i>jflag</i> is set to zero, then the force/torque acting on <i>n</i>₁ end of the beam is returned; otherwise if <i>jflag</i> is set to 1, the force/torque on the <i>n</i>₂ end of the beam is returned. See *ELEMENT_BEAM for the nodal connectivity rule defining <i>n</i>₁ and <i>n</i>₂.</p> <p>Admissible values of <i>comp</i> are 1-8 and correspond to the following components:</p> <ul style="list-style-type: none"> comp.EQ.1: force magnitude comp.EQ.2: <i>x</i> force (axial <i>r</i>-force, <i>rm</i> = -1) comp.EQ.3: <i>y</i> force (<i>s</i>-shear force, <i>rm</i> = -1) comp.EQ.4: <i>z</i> force (<i>t</i>-shear force, <i>rm</i> = -1) |

| FUNCTION | DESCRIPTION |
|--|---|
| | <p>comp.EQ.5: torque magnitude</p> <p>comp.EQ.6: x torque (torsion, $rm = -1$)</p> <p>comp.EQ.7: y torque (s-moment, $rm = -1$)</p> <p>comp.EQ.8: z torque (t-moment, $rm = -1$)</p> |
| <p>ELHIST(<i>eid</i>, <i>etype</i>, <i>comp</i>, <i>ipt</i>, <i>local</i>)</p> | <p>Returns the elemental quantity <i>comp</i> (see description below) of element <i>eid</i> as calculated in the local coordinate system <i>local</i>. Quantities are reported in the global coordinate system if <i>local</i> is zero. The parameter <i>ipt</i> specifies whether the quantity is for a particular integration point or maximum, minimum, or averaging is applied across the integration points.</p> <p>The following element classes, specified with <i>etype</i>, are supported:</p> <p>etype.EQ.0: solid</p> <p>etype.EQ.2: thin shell</p> <p>Following are admissible values of <i>comp</i> and the corresponding elemental quantity:</p> <p>comp.EQ.1: x stress</p> <p>comp.EQ.2: y stress</p> <p>comp.EQ.3: z stress</p> <p>comp.EQ.4: xy stress</p> <p>comp.EQ.5: yz stress</p> <p>comp.EQ.6: zx stress</p> <p>comp.EQ.7: effective plastic strain</p> <p>comp.EQ.8: hydrostatic pressure</p> <p>comp.EQ.9: effective stress</p> <p>comp.EQ.11: x strain</p> <p>comp.EQ.12: y strain</p> <p>comp.EQ.13: z strain</p> <p>comp.EQ.14: xy strain</p> <p>comp.EQ.15: yz strain</p> |

| FUNCTION | DESCRIPTION |
|-------------------------------------|---|
| JOINT(<i>id, jflag, comp, rm</i>) | <p>comp.EQ.16: zx strain</p> <p>Integration point options, specified with <i>ipt</i>, are:</p> <ul style="list-style-type: none"> ipt.GE.1: quantity is reported for integration point number <i>ipt</i> ipt.EQ.-1: maximum of all integration points (default) ipt.EQ.-2: average of all integration points ipt.EQ.-3: minimum of all integration points ipt.EQ.-4: lower surface integration point ipt.EQ.-5: upper surface integration point ipt.EQ.-6: middle surface integration point <p>The local coordinate option <i>local</i> currently defaults to the global coordinate system for solid elements and other coordinate system options are unavailable. In the case of thin shell elements the quantity is reported only in the element local coordinate system.</p> <ul style="list-style-type: none"> local.EQ.1: global coordinate system (solid elements) local.EQ.2: element coordinate system (thin shell elements) <p>Returns the force component <i>comp</i> (see description below) due to rigid body joint <i>id</i> as calculated in the local coordinate system <i>rm</i>. If <i>jflag</i> is set to zero, then the force/torque acting on n_1 end of the joint is returned. The force/torque on the n_2 end of the joint is returned if <i>jflag</i> is set to 1. See *CONSTRAINED_JOINT for the rule defining n_1 and n_2.</p> <p>Admissible values of <i>comp</i> are 1-8 and correspond to the following components:</p> <ul style="list-style-type: none"> comp.EQ.1: force magnitude comp.EQ.2: x force |

| FUNCTION | DESCRIPTION |
|----------|-----------------------------|
| | comp.EQ.3: y force |
| | comp.EQ.4: z force |
| | comp.EQ.5: torque magnitude |
| | comp.EQ.6: x torque |
| | comp.EQ.7: y torque |
| | comp.EQ.8: z torque |

Nodal Specific Functions:

| FUNCTION | DESCRIPTION |
|-------------|--|
| TEMP(n) | Returns the temperature of node n |
| EPOT(n) | Returns the electric potential of node n of a piezoelectric material |

General Functions

| FUNCTION | DESCRIPTION |
|---------------------------------------|---|
| CHEBY($x, x_0, a_0, \dots, a_{30}$) | <p>Evaluates a Chebyshev polynomial at the user specified value x. The parameters $x_0, a_0, a_1, \dots, a_{30}$ are used to define the constants for the polynomial defined by:</p> $C(x) = \sum a_j T_j(x - x_0)$ <p>where the functions T_j is defined recursively as</p> $T_j(x - x_0) = 2(x - x_0)T_{j-1}(x - x_0) - T_{j-2}(x - x_0)$ <p>where</p> $T_0(x - x_0) = 1$ $T_1(x - x_0) = x - x_0$ |

| FUNCTION | DESCRIPTION |
|--|--|
| FORCOS($x, x_0, \omega[, a_0, \dots, a_{30}]$) | <p>Evaluates a Fourier cosine series at the user specified value x. The parameters $x_0, a_0, a_1, \dots, a_{30}$ are used to define the constants for the series defined by:</p> $F(x) = \sum a_j T_j(x - x_0)$ <p>where</p> $T_j(x - x_0) = \cos[j\omega(x - x_0)]$ |
| FORSIN($x, x_0, \omega[, a_0, \dots, a_{30}]$) | <p>Evaluates a Fourier sine series at the user specified value x. The parameters $x_0, a_0, a_1, \dots, a_{30}$ are used to define the constants for the series defined by:</p> $F(x) = \sum a_j T_j(x - x_0)$ <p>where</p> $T_j(x - x_0) = \sin[j\omega(x - x_0)]$ |
| IF(a_1, a_2, a_3, a_4) | <p>Arithmetic if conditional where a_i can be a constant or any legal expression described in *DEFINE_CURVE_FUNCTION. For example, $a_1 = 'CX(100)'$ sets the first argument to be the x-coordinate of node 100.</p> $\text{IF} = \begin{cases} \text{the value of } a_2 & \text{if the value of } a_1 < 0 \\ \text{the value of } a_3 & \text{if the value of } a_1 = 0 \\ \text{the value of } a_4 & \text{if the value of } a_1 > 0 \end{cases}$ |
| PIDCTL($meas, ref, kp, ki, kd, tf, ei0, sint, umin, umax$) | <p>Evaluates the control signal of a PID controller</p> $u(t) = kp \times e(t) + ki \times \int_0^t e(\tau) d\tau + kd \times \frac{de(t)}{dt}$ <p>where $e(t)$ is the control error defined as the difference between the reference value ref and the measured value, $meas$</p> $e(t) = ref - meas$ <p>The control parameters are proportional gain kp, integral gain ki, derivative gain kd and low-pass filter tf for the derivative calculation</p> $\frac{de(t_n)}{dt} = \frac{de(t_{n-1})}{dt} \frac{tf}{\Delta t + tf} + \frac{\Delta t}{\Delta t + tf} \times \frac{e(t_n) - e(t_{n-1})}{\Delta t}$ <p>$ei0$ is the initial integral value at time = 0.</p> |

| FUNCTION | DESCRIPTION |
|--|---|
| | <p><i>sint</i> is the sampling interval. <i>umin</i> and <i>umax</i>, the lower and upper limit of a control signal, can be used to represent the saturation limits of an actuator. When the signal is not within the limits, it is clipped to the saturation limit, that is, integration is skipped to avoid integrator wind-up.</p> <p>Input parameter can be a constant or any legal expression described in *DEFINE_CURVE_FUNCTION. For example, <i>meas</i> = 'CX(100)' measures the x-coordinate of node 100, <i>ref</i> = 'LC200' uses curve 200 as the reference value.</p> |
| POLY(<i>x</i> , <i>x</i> ₀ , <i>a</i> ₀ , ..., <i>a</i> ₃₀) | <p>Evaluates a standard polynomial at the user specified value <i>x</i>. The parameters <i>x</i>₀, <i>a</i>₀, <i>a</i>₁, ..., <i>a</i>₃₀ are used to define the constants for the polynomial defined by:</p> $P(x) = a_0 + a_1(x - x_0) + a_2(x - x_0)^2 + \dots + a_n(x - x_0)^n$ |
| SHF(<i>x</i> , <i>x</i> ₀ , <i>a</i> , ω [, ϕ , <i>b</i>]) | <p>Evaluates a Fourier sine series at the user specified value <i>x</i>. The parameters <i>x</i>₀, <i>a</i>₀, <i>a</i>₁, ..., <i>a</i>₃₀ are used to define the constants for the series defined by:</p> $SHF = a \sin[\omega(x - x_0) - \phi] + b$ |
| STEP(<i>x</i> , <i>x</i> ₀ , <i>h</i> ₀ , <i>x</i> ₁ , <i>h</i> ₁) | <p>Approximates the Heaviside function with a cubic polynomial using the equation:</p> $STEP = \begin{cases} h_0 & \text{if } x \leq x_0 \\ h_0 + (h_1 - h_0) \left[\frac{(x - x_0)}{(x_1 - x_0)} \right]^2 \left\{ 3 - 2 \left[\frac{(x - x_0)}{(x_1 - x_0)} \right] \right\} & \text{if } x_0 < x < x_1 \\ h_1 & \text{if } x \geq x_1 \end{cases}$ |

Electromagnetic solver (EM) Functions

| FUNCTION | DESCRIPTION |
|---|--|
| EM_ELHIST(<i>iele</i> , <i>ifield</i> , <i>idir</i>) | Returns the elemental quantity of element <i>iele</i> in the global reference frame. |
| EM_NDHIST(<i>inode</i> , <i>ifield</i> , <i>idir</i>) | Returns the nodal quantity of node <i>inode</i> in the global reference frame. |

| FUNCTION | DESCRIPTION |
|---|--|
| RM_PAHIST(<i>ipart, ifield, idir</i>) | <p>Returns the value integrated over the whole part given by <i>ipart</i>. <i>ifield</i> can be 7, 8 and 11 only.</p> <p>Admissible values of <i>ifield</i> are 1-10 and correspond to the following variables:</p> <ul style="list-style-type: none"> comp.EQ.1: scalar potential comp.EQ.2: vector potential comp.EQ.3: electric field comp.EQ.4: B field comp.EQ.5: H field comp.EQ.6: current density comp.EQ.7: Lorentz force comp.EQ.8: current density comp.EQ.9: Lorentz force comp.EQ.10: relative permeability comp.EQ.11: magnetic energy (in the conductor only) <p>Admissible values of <i>idir</i> are 1-4 and correspond to the following components:</p> <ul style="list-style-type: none"> comp.EQ.1: <i>x</i>-component comp.EQ.2: <i>y</i>-component comp.EQ.3: <i>z</i>-component comp.EQ.4: norm |

Remarks:

1. **Local Coordinate Systems Required for Rotational Motion.** A local coordinate system *must* be attached to nodes if they are referenced by functions involving rotational motion, for example, angular displacement or angular velocity. The local coordinate system is attached to the node using *DEFINE_COORDINATE_NODES and FLAG = 1 is a requirement. Furthermore, the three nodes which comprise the coordinate system must lie on the same body. Similarly, a local coordinate system must also be attached to node n_3 if n_3 is referenced in functions: DX, DY, DZ, VX, VY, VZ, WX, WY, WZ, ACCX, ACCY, ACCZ, WDTX, WDTY, WDTZ, FX, FY, FZ, TX, TY, or TZ.

2. **Default is Radians.** Unless otherwise noted units of radians are always used for the arguments and output of functions involving angular measures.

The following examples serve only as an illustration of syntax.

Example 1:

Define a curve 10 whose ordinate is,

$$f(x) = \frac{1}{2} (\text{ordinate of load curve 9}) \times (\text{magnitude of translation velocity at node 22})^3.$$

```
*DEFINE_CURVE_FUNCTION
10
0.5*lc9*vm(22)**3
```

Example 2:

Define a curve 101 whose ordinate is,

$$f(x) = -2(z \text{ translational displacement of node 38}) \times \sin(20\pi t).$$

```
*DEFINE_CURVE_FUNCTION
101
-2.*dz(38)*sin(2.*pi*10.*time)
```

Example 3:

Define a curve 202 whose ordinate is,

$$f(x) = \begin{cases} \cos(4\pi t) & \text{if } t \leq 5. \\ 0. & \text{if } t > 5. \end{cases}$$

```
*DEFINE_CURVE_FUNCTION
202
If (TIME-5., COS (4.*PI*TIME) , COS (4.*PI*TIME) , 0.)
```

*DEFINE_CURVE_SMOOTH

Purpose: Define a smoothly varying curve using few parameters. This shape is useful for velocity control of tools in metal forming applications.

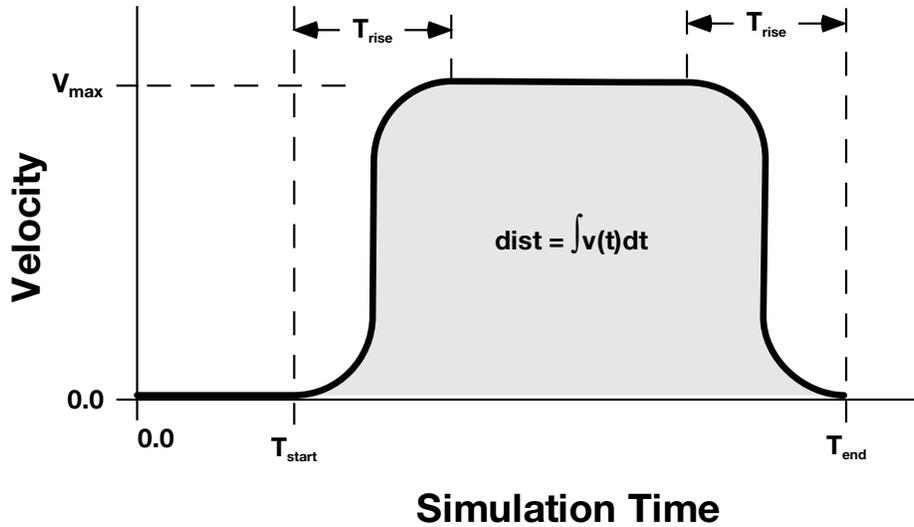

Figure 15-21. Smooth curve created automatically using *DEFINE_CURVE_SMOOTH. This shape is commonly used to control velocity of tools in metal forming applications as shown in the above graph, but can be used for other applications in place of any standard load curve.

VARIABLE

DESCRIPTION

LCID

Load curve ID, must be unique.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| SIDR | Stress initialization by dynamic relaxation: EQ.0: load curve used in transient analysis only or for other applications, EQ.1: load curve used in stress initialization but not transient analysis, EQ.2: load curve applies to both initialization and transient analysis. |
| DIST | Total distance tool will travel (area under curve). |
| TSTART | Time curve starts to rise |
| TEND | Time curve returns to zero. If TEND is nonzero, VMAX will be computed automatically to satisfy required travel distance DIST. Input either TEND or VMAX. |
| TRISE | Rise time |
| VMAX | Maximum velocity (maximum value of curve). If VMAX is nonzero, TEND will be computed automatically to satisfy required travel distance DIST. Input either TEND or VMAX. |

***DEFINE_CURVE_STRESS**

Purpose: This keyword defines a material hardening curve based on a few commonly used material hardening laws. The hardening curve can also be a weighted combination of some of the laws. The load curve ID for this curve can be referenced in the load curve ID field used by a specific material model. This feature is applicable to all material models with a hardening curve that can be defined by a load curve using *DEFINE_CURVE.

Curve Definition Card(s). Only one card is needed unless ITYPE = 11. When ITYPE = 11, a second card with the form of CARD 1 is needed with the same LCID as the first card. See [Remark 2](#).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|------|----|------|------|------|------|
| Variable | LCID | ITYPE | P1 | P2 | P3 | P4 | P5 | P6 |
| Type | I | I | F | F | F | F | F | F |
| Default | none | none | none | 1 | none | none | none | none |

VARIABLE**DESCRIPTION**

LCID

Load curve ID for the stress-strain curve to be generated.

ITYPE

Type of hardening law:

EQ.1: Swift power law:

$$\sigma = K(e_0 + \epsilon_p)^n,$$

where σ is true effective stress, e_0 is the elastic strain at the initial yield point, K is a strength coefficient, ϵ_p is true effective plastic strain, and n is the work hardening coefficient.

EQ.2: Voce law with form:

$$\sigma = \sigma_0 + R_{\text{sat}}(1.0 - e^{-\zeta\epsilon_p}),$$

where σ_0 is the initial yield stress, R_{sat} is the stress differential between σ_0 and the saturated stress, and ζ is a strain coefficient.

EQ.3: Voce law with form:

$$\sigma = A - Be^{-C\epsilon_p},$$

VARIABLE **DESCRIPTION**

where $A, B,$ and C are material constants.

EQ.4: Hockett-Sherby law:

$$\sigma = A - Be^{-C\epsilon_p^H},$$

where $A, B, C,$ and H are material constants.

EQ.5: Stoughton-Yoon hardening law:

$$\sigma = A - Be^{-C\epsilon_p^m} + D\epsilon_p,$$

where A, B, C, m and D are material constants, such that $0 < m < 1.0$ and $D \geq 0.0$. According to Stoughton-Yoon, "with the exception of metals exhibiting Yield Point Elongation (YPE) effects, this function can represent the stress-strain response for both mild and AHSS steel and aluminum, from the initial yield point, throughout the small strain range, up to the highest strains realized in bulge tests". Note that if $D = 0.0$, this law reduces to the Hockett-Sherby law (ITYPE = 4). Also note that if $m = 1.0$ and $D = 0.0$, this law reduces to the ITYPE = 3 Voce law.

EQ.11: A weighted combination of ITYPE = 1 and any of the other ITYPEs. See [Remark 2](#).

P1, P2, P3
P4, P5, P6

| ITYPE | P1 | P2 | P3 | P4 | P5 | P6 |
|-------|------------|------------------|---------|-------|-------|-------|
| 1 | K | e_0 | n | | | |
| 2 | σ_0 | R_{sat} | ζ | w_2 | | |
| 3 | A | B | C | H | w_2 | |
| 4 | A | B | C | H | w_2 | |
| 5 | A | B | C | M | D | w_2 |
| 11 | K | e_0 | n | w_1 | | |

Where w_1 and w_2 are the weighting factors used for ITYPE = 11; see [Remark 2](#).

Remarks:

- Default for P2.** For ITYPE = 1, the default value for P2 is 0.001.

- 2. **Combining Hardening Laws.** With ITYPE = 11, the Swift power law (ITYPE = 1) can be combined with another law through a weighted sum. To do this two cards are needed with the same LCID. The first card has ITYPE = 11 in place of ITYPE = 1. This card also requires a weight, w_1 , in the P4 field which is the weight applied to the Swift power law in the sum. The second card has the ITYPE of the law that is being summed to the Swift power law. This card also requires a weight, w_2 , in the P_i field specified for that ITYPE. The following example generates a hardening curve (LCID 90903) that is the sum of 0.5 (w_1) times the Swift power law and 0.8 (w_2) times the Hockett-Sherby law (ITYPE = 4). This curve then has the equation

$$\sigma = 0.5(350.0(0.01 + \epsilon_p)^{0.22}) + 0.8(162.2 - 72.2e^{-4.34\epsilon_p^{1.2}})$$

```

*DEFINE

*DEFINE_CURVE_TRIAXIAL_LIMIT_FROM_FLD

*DEFINE_CURVE_TRIAXIAL_LIMIT_FROM_FLD

Purpose: This keyword creates a stress triaxial limit curve from a given forming limit diagram (FLD) curve, which can be referred to by material models utilizing a stress triaxial limit curve, such as *MAT_ADD_EROSION or *MAT_260B, or by keywords such as *CONTROL_FORMING_ONESTEP, etc. The conversion assumes plane stress and Von-Mises yield criterion. The converted stress triaxial curve can be found in the ".o" file (a scratch file from batch queue run). Another related keyword is: *DEFINE_CURVE_FLD_FROM_TRIAXIAL_LIMIT.

VARIABLE

DESCRIPTION

| | |
|-------------|--|
| LCID | The stress triaxial limit curve ID to be created. |
| A1, A2, ... | Abscissas represent minor true strains of a FLD curve. |
| O1, O2, ... | Ordinates represent major true strains of a FLD curve. |

Remarks:

1. In an example of the keyword shown below, the input FLD limit curve is obtained from *Li, Yaning et al, "Prediction of shear-induced fracture in sheet metal forming," Journals of Material Processing Technology, Volume 210, issue 14, (2010).* Using a uniaxial tension model on a single element, calculated stress triaxial curve from LS-DYNA is shown in [Figure 15-22](#), which matches the triaxial curve from the paper.

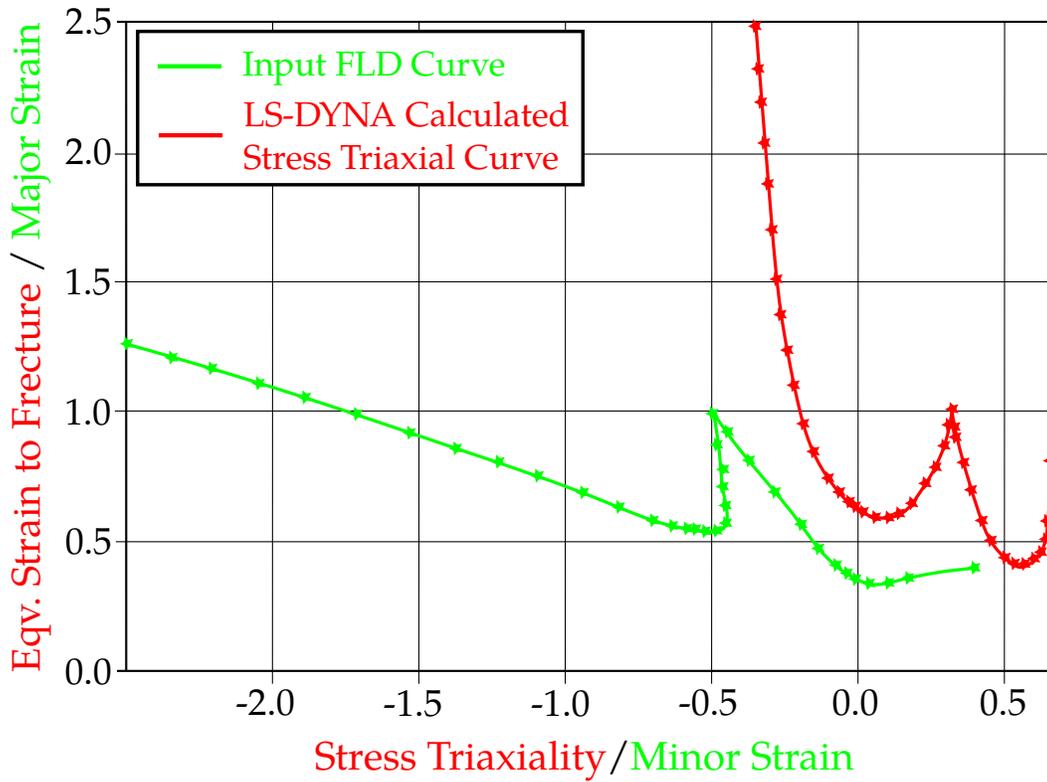

Figure 15-22. LS-DYNA calculated stress triaxial curve from FLD curve. Reference: Li, Yaning et al, "Prediction of shear-induced fracture in sheet metal forming," *Journals of Material Processing Technology*, Volume 210, issue 14, (2010).

Revision Information:

This feature is available starting from Revision 116631.

***DEFINE_CURVE_TRIM_{OPTION}**

Available options include:

<BLANK>

3D

2D

Purpose: This keyword is developed to define curves and controls for sheet blank trimming in sheet metal forming. It can also be used to define mesh adaptivity along a curve within a band prior to the start of a simulation, using the variable TCTOL in this keyword and *CONTROL_ADAPTIVE_CURVE.

NOTE: The option NEW was replaced by 2D starting in Revision 115518.

When the option 3D is used, the trimming is processed based on the element normal rather than a vector. The option 2D is used to trim in a fixed direction specified by a vector, and is also called 2D trimming. Currently this keyword applies to:

- 2D and 3D trimming of shell elements,
- 2D and 3D trimming of solids,
- 2D and 3D adaptive trimming of adaptive-meshed sandwiched parts (limit to a core of one layer of solid elements with outer layers of shell elements, see "IFSAND" under *CONTROL_ADAPTIVE),
- 2D and 3D trimming of non-adaptive sandwiched parts (a core of multiple layers of solid elements with outer layers of shell elements), and,
- 2D trimming of thick shell elements (TSHELL).

This keyword is not applicable to axisymmetric solids or 2D plane strain/stress elements. Related keywords include *ELEMENT_TRIM, *CONTROL_FORMING_TRIMMING, *CONTROL_ADAPTIVE_CURVE, *INCLUDE_TRIM, and *INCLUDE. Another closely related keyword is *CONTROL_FORMING_TRIM_MERGE, which automatically closes an open trim curve with a user-specified tolerance.

Trimming of shell and solid elements are supported starting in *LS-PrePost 4.0* and *LS-PrePost 4.3*, respectively, under *Application* → *MetalForming* → *Easy Setup*.

VARIABLE

DESCRIPTION

TCID

ID number for trim curve.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| TCTYPE | <p>Trim curve type:</p> <p>EQ.1: Curve data in XYZ format, obtained following procedures outlined in Figures under *INTERFACE_-BLANKSIZE. In addition, only this format is allowed in *INTERFACE_COMPENSATION_3D.</p> <p>EQ.2: IGES trim curve.</p> |
| TFLG | <p>Element removal option (applies to option 2D only):</p> <p>EQ.-1: remove material outside curve;</p> <p>EQ.1: remove material inside curve.</p> |
| TDIR | <p>If the option 2D is used, this is the ID of a vector (*DEFINE_VECTOR) giving the trim direction (see Figure 15-23).</p> <p>EQ.0: default vector (0.0,0.0,1.0) is used. Curve is defined in global XY plane, and projected onto mesh in global Z-direction to define trim line.</p> <p>If the option 3D is used, TDIR is used to indicate whether the trim curve is near the top or bottom surface of the solids or laminates (>Revision 101964), see Trimming.</p> <p>EQ.1: trim curve is located near the top surface (default).</p> <p>EQ.-1: trim curve is located near the bottom surface.</p> |
| TCTOL | <p>Tolerance limiting size of small elements created during trimming (see Figure 15-24).</p> <p>LT.0: "simple" trimming, producing jagged edge mesh</p> <p>When used together with *CONTROL_ADAPTIVE_CURVE, it is a distance from the curve out (both sides). Within this distance the blank mesh will be refined, as stated in remarks below.</p> |

| VARIABLE | DESCRIPTION |
|-------------------|--|
| TOLN / IGB | <p>If the option 3D is used, TOLN represents the maximum gap between the trimming curve and the mesh. If the gap is bigger than this value, this section in the curve will not be used.</p> <p>If the option 2D is used, then the variable IGB is defined as follows:</p> <p style="padding-left: 40px;">IGB.EQ.0: trimming curve is defined in local coordinate system. This is the default value. If this value is chosen for IGB, then the variable TDIR and the keyword *DEFINE_VECTOR need to be defined according to Figure 15-23.</p> <p style="padding-left: 40px;">IGB.EQ.1: trimming curve is defined in global coordinate system.</p> |
| NSEED1/ NSEED2 | <p>A node ID on the blank in the area that remains after trimming, applicable to both options 3D or 2D.</p> <p style="padding-left: 40px;">LT.0: positive number is a node ID, which may not necessarily be from the blank, referring to remarks below.</p> |
| CX, CY, CZ | X, Y, Z-coordinate of trim curve. Define if and only if TCTYPE = 1. |
| FILENAME | Name of IGES database containing trim curve(s). Define if and only if TCTYPE = 2. |

Trimming capability summary:

This keyword and its options deal with trimming of the following scenarios:

| | 2D (along one direction) | 3D (element normal) | 2D & 3D Double Trim | Adaptive mesh |
|------------------|---------------------------------|----------------------------|--------------------------------|--|
| Shell | Yes | Yes | Yes | Yes |
| Solids | Yes | Yes | Yes | N/A |
| Laminates | Yes | Yes | Yes | One layer of solids only; Multiple layers of solids okay for non-adaptive mesh. |

| | | | | |
|--------|-----|-----|-----|-----|
| TSHELL | Yes | N/A | N/A | N/A |
|--------|-----|-----|-----|-----|

About the options and trim curves:

The option 2D activates a new searching algorithm, which enables a much faster trimming operation compared with option 3D. For big models, the improvement in computational efficiency of the 2D option is significant. In addition, users are required to pick a seed node (or position coordinates), as is the case with the 3D option. Both options are now available under the “Trimming” feature of *LS-PrePost 4.0’s* eZ-Setup for metal forming application (<http://ftp.lstc.com/anonymous/outgoing/lsprepost/4.0/-metalfforming/>). Only IGES entities 110 and 106 are supported when using the TCTYPE of 2. The eZ-Setup for trimming function ensures correct IGES files are written for trimming simulation.

For the option 2D, Revision 68643 and later releases enable trimming of a part where trim lines go beyond the part boundary. This is illustrated in [Figure 15-29](#).

Enclosed trimming curves (same start and end points) are required for all options. Furthermore, for each enclosed trimming curve, only one curve segment is acceptable for the option 3D; while several curve segments are acceptable with the option 2D. Curves can be manipulated through the use of *Merge* and *break* features in *LS-PrePost4.0*, found under *Curve/Merge* (always select *piecewise* under *Merge*) and *break*.

In case of 3D trimming, trim curves need to be sufficiently close to the part. A feature of curve projection to the mesh in *LS-PrePost* can be used to process the trim curves. The feature is accessible under *GeoTol/Project/Closest Proj/Project to Element/By Part*. Double precision LS-DYNA executable may also help in this situation.

Choice of 2D or 3D trimming depends on the to-be-trimmed part geometry. 2D trimming can be used if trimming is to be done on the relatively flat area of the part, while 3D trimming must be selected for trimming on a inclined or vertical draw wall area for precise trimming.

Seed node definition:

This keyword in combination with *ELEMENT_TRIM trims the requested parts before a job starts (pre-trimming), and can handle adaptive mesh. If the keyword *ELEMENT_TRIM does not exist the parts are trimmed after the job is terminated (post-trimming).

Seed node is used to define which side of the drawn panel to be kept after the trimming. With the frequent application of adaptive re-meshing, the seed node for trimming is often unknown until the draw forming is complete. With the negative NSEED variable,

an extra node unrelated to the blank and tools can be created for the definition of the seed node, enabling trimming process independent of the previous process simulation results. The extra node can be defined using keyword *NODE. A partial keyword input example for the trimming of a double-attached *NUMISHEET2002 fender outer* with the option 2D is listed below, where a 2D trimming is performed with IGES file *doubletrim.iges* in the global Z-axis, with two nodes of negative ID 43356 and 18764 assigned to the variables NSEED1 and NSEED2, respectively. The two seed nodes are defined off the stationary lower post, and do not necessarily need to be a part of the post, as shown in [Figure 15-25](#). The drawn panels in wire frame are shown in [Figure 15-26](#), along with the thickness/thinning contour ([Figure 15-27](#)). In [Figure 15-28](#), the drawn panels are trimmed and separated.

```

If the seed node is too far away from the blank it will be projected to the blank and the new position will be used as the seed node. Typically, this node can be selected from the stationary tool in its home position.

Alternatively, if the variable NSEEDs are not defined, the seeds can be defined using *DEFINE_TRIM_SEED_POINT_COORDINATES. A partial keyword input is provided below for trimming of the same double-attached fender outer.

```

```

Again, selecting a seed node is quite easy in “Trimming” process of *LS-PrePost4.0* eZSetup for metal forming application.

General adaptive re-meshing and element fixing during trimming:

In case of large element size along the trim curves, the blank mesh can be pre-adapted along the trim curves before trimming by adding the keyword `*CONTROL_ADAPTIVE_CURVE` to the above example for a better quality trim edge. The following indicates refining meshes for part set ID 1 no more than three levels along the trim curves, or until element size reaches 3.0: Care should be taken since too small of the value `SMIN` and too large value of `N` could result in excessive amount of elements to be generated.

```

*CONTROL_ADAPTIVE_CURVE
$#   IDSET   ITYPE   N       SMIN   ITRIOPT
      1       2         3       3.0     0

```

Sometimes it is helpful to conduct a check of the trimmed mesh along the edge in the same trimming input deck using the keyword `*CONTROL_CHECK_SHELL`. This is especially useful for the next continued process simulation. For detailed usage, check for an updated remarks for the keyword.

The trimming tolerance `TCTOL` limits the size of the smallest element created during trimming. A value of 0.0 places no limit on element size. A value of 0.5 restricts new elements to be at least half of the size of the parent element. A value of 1.0 allows no new elements to be generated, only repositioning of existing nodes to lie on the trim curve. A negative tolerance value activates "simple" trimming, where entire elements are removed, leaving a jagged edge.

Trimming with nodal temperature:

Starting in Revision 81105, trimming of blank with nodal temperature (related to hot and warm stamping) is available. At the end of the trimming, the file `new_temp_ic.inc` will be output along with the usual `dynain` file. Furthermore, the keyword `*CONTROL_CHECK_SHELL` can be used together when trimming with nodal temperature.

TCTOL used as mesh refinement width along a curve:

The variable TCTOL can be used to control the mesh refinement along a curve when used together with *CONTROL_ADAPTIVE_CURVE. In this scenario, it is the distance of the entire refinement width. The mesh will be refined in the beginning of the simulation. This method offers greater control on the number of elements to be generated during mesh refinement, as compared to that without using this variable. A detailed description and example is provided under the manual section under *CONTROL_ADAPTIVE_CURVE.

The keyword *INCLUDE_TRIM is recommended to be used at all times, either for trimming or for mesh refinement purpose, except in case where to-be-trimmed sheet blank has no stress and strain information (no *INITIAL_STRESS_SHELL, and *INITIAL_STRAIN_SHELL cards present in the sheet blank keyword or dynain file), the keyword *INCLUDE must be used. A check box to indicate that the blank is free of stress and strain information is provided in the “Trimming” process in the eZ-Setup for users to set up a trimming input deck under the circumstance.

2D and 3D trimming of solid elements and laminates:**Trimming curve preparation, file inclusion, etc.**

The requirement for trimming curves definition of solids in case of 3D trimming is different from that of shell trimming. The trim curve should be created based on solid element normal. If trim curve is created closer to the top surface, the variable TDIR should be set to 1; if closer to the bottom surface, set to -1, see [Figure 15-32](#).

Normal directions of solid elements can be viewed using *LS-PrePost* starting in *version 4.2* with the menu option of *EleTol* → *Normal* → *Entity Type: Solid* → *By Part*, and set a large *V-Size*. In addition, when defining a trim curve for the 3D trimming of both solids and laminates, the curve should be as close to either the top or bottom side of the part as possible to enable a successful trimming. This is especially true if wrinkles are present in the panels to be trimmed. *LS-PrePost* can be used to project the curves to the part, via menu option: *GeoTol* → *Project* → *Closest proj* → *Project to Element*. Either top or bottom side of the part can be selected as “*Element*” by part. The curves may need to be refined with more points before projection, using menu option: *Curves* → *Method: Respace* → *By number*. Sufficient number of points may be entered to capture the sheet metal surface contour.

For solid element trimming, the keyword *INCLUDE_TRIM *must* be used. In other words, the dynain file from a previous process (for example, a forming simulation) must be included in a main trim file using *INCLUDE_TRIM (not *INCLUDE).

2D trimming of solid elements

As of Revision 92088, 2D (option **2D**) trimming in any direction (defined by a vector) of solid elements is available. An illustration of the 2D trim is shown in [Figure 15-30](#). A partial keyword example is provided below, where trim curves trimcurves2d.iges is being used to perform a solid element trimming along a vector defined along the global Z-axis.

```

Currently, 2D trimming of solids in some cases may be approximate. The trimming will trim the top and bottom sides of the elements, not crossing over to the other sides. This can be seen, for instance, trimming involving a radius.

3D (normal) trimming of solid elements

As of Revision 93467 3D trimming (option **3D**) of solid elements is available. From the previous input, in case of 3D trimming, the option **2D** is changed to **3D**, and trim curves trimcurves3d.iges is used. In the example below, the variable TDIR is set to "1" since

the trim curve is on the positive side of the element normal (Figure 15-32). Since 3D trimming are along the element normal directions, *DEFINE_VECTOR card is no longer needed.

```
*DEFINE_CURVE_TRIM_3D
$#   tcid   tctype   tflg   tdir   tctol   toln   nseed1   nseed2
      2     2         0       1   0.10000  1.000000   0         0
$# filename
trimcurves3d.iges
```

Again, the projection of trim curves onto either the top or bottom surface of the blank is important to ensure a smooth and successful trimming.

2D and 3D trimming of non-adaptive-meshed sandwiched parts (laminates)

2D and 3D trimming of non-adaptive-meshed laminates are available starting in Revision 92289. Trimming of the laminates can have multiple layers of solid elements, sandwiched by a top and a bottom layer of shell elements. Note that the nodes of shell elements must share the nodes with solid elements at the top and bottom layers. An illustration of the trim is shown in Figure 15-31. The input deck is similar to those used for trimming of solid elements, except the variable ITYP under *CONTROL_FORMING_TRIMMING should be set to "1" to activate the trimming of laminates in both 2D and 3D conditions:

```
*CONTROL_FORMING_TRIMMING
$---+-----1-----+-----2-----+-----3-----+-----4-----+-----5-----+-----6-----+-----7-----+-----8
$   PSID                               ITYP
   &blksid                             1
```

Again, in the case of 3D trimming, the projection of trim curves onto either the top or bottom surface of the blank is important to ensure a smooth and successful trim.

2D and 3D trimming of adaptive-meshed sandwiched parts (laminates)

2D and 3D trimming of adaptive-meshed laminates are available starting in Revision 108770. Trimming of the laminates is limited to one core layer of solid elements, sandwiched by a top and a bottom layer of shell elements. Shell elements share the same nodes as the solid elements.

Note elements are refined automatically along the trim curves until no slave nodes would be cut by the trim curves. In addition, the keyword *CONTROL_ADAPTIVE_CURVE must not be used, since it is only applied to shell elements, and would cause error termination otherwise. Furthermore, unlike the mesh refinement along the trim curve during shell element trimming, this trimming requires no additional adaptivity-related keyword inputs. An example of the trimming on the 2005 NUMISHEET Cross Member is shown in Figure 15-33.

Again, in the case of 3D trimming, the projection of trim curves onto either the top or bottom surface of the blank is important to ensure a smooth and successful trim.

Summary – trimming of solids and laminates

In summary, the trimming input files between solids/laminates and shells are different in a few ways. For solids, *SECTION_SOLID is needed in place of *SECTION_SHELL. For laminates, in addition to setting the ITYP = 1 in *CONTROL_FORMING_TRIMMING, both *SECTION_SHELL and *SECTION_SOLID need to be defined. The position of a trim curve for 3D trimming of solids needs to be defined according to [Figure 15-32](#).

Adaptive-meshed sandwiched parts (limit to a core of one layer of solid elements with outer layers of shell elements) can be 2D or 3D trimmed with adaptive mesh refinement along the trim curves.

Non-adaptive-meshed sandwiched parts (a core of multiple layers of solid elements with outer layers of shell elements) can be 2D and 3D trimmed.

In all trimming of solids and laminates, only dynain file is written out (no d3plot files will be output), and finally, *INCLUDE_TRIM is to be used.

In the case of 3D trimming, the projection of trim curves onto either the top or bottom surface of the blank is important to ensure a smooth and successful trim.

2D trimming of thick shell elements (TSHELL):

2D trimming of TSHELL is supported starting from Revision 107957. Note by definition, TSHELL has only one layer of solid elements, and is defined by keyword *SECTION_TSHELL. Note also *INCLUDE_TRIM (not *INCLUDE) must be used to include the dynain file to be trimmed.

Input deck for 2D trimming of TSHELL is similar to what is used for trimming of solid elements.

2D and 3D trimming of double-attached solids and laminates:

These features are available starting in Revision 110140. Both seed point coordinates can be specified in *DEFINE_TRIM_SEED_POINT_COORDINATES to define a seed coordinate for each part, as shown below:

```
*DEFINE_TRIM_SEED_POINT_COORDINATES
$  NSEED      X1      Y1      Z1      X2      Y2      Z2
      2  -184.565    84.755    78.392  -1038.41  119.154    78.375
```

In [Figure 15-34](#), a 2D double-trimming example on a sandwiched part is shown using the 2005 NUMISHEET cross member. Two trim curves, two seed nodes are defined for each to be trimmed portion. The coordinates for seed node #1 is (-184.565, 84.755,

78.392) and is (-1038.41, 119.154, 78.375) for seed node #2. Trimmed results are satisfactory.

Revision information:

Revision information are as follows:

1. Revision 54608 and 52312: negative seed node option is available for the options **3D** and **2D**, respectively.
2. Revision 65630: use of TCTOL as a distance for mesh refinement (when used together with *CONTROL_ADAPTIVE_CURVE). TCTOL is the distance from the curve to the edge of the refinement.
3. Revision 68643: trimming is enabled for those trim lines going beyond the part boundary.
4. Revision 81105: allow nodal temperature; allow *CONTROL_CHECK_SHELL to be used together when trimming with nodal temperature.
5. Revision 92088: 2D (option **2D**) trimming of solid elements.
6. Revision 92289: 2D and 3-D (option **3D**) trimming of laminates.
7. Revision 93467: 3D trimming of solid elements.
8. Revision 101964: TDIR definition activated for 3D trimming of top and bottom surfaces of solid elements and laminates.
9. Revision 107957: 2D trimming of TSHELL.
10. Revision 109047: 2D and 3D trimming of adaptive-meshed sandwiched part.
11. Revision 110140: 2D and 3D trimming of solids and laminates of double-attached parts.
12. Revision 113756: some improvements to TCTOL. TCTOL becomes the distance of the entire width of the refinement.
13. The option NEW was replaced by 2D starting in Revision 115518
14. Latter Revisions may incorporate more improvements and are suggested to be used for trimming.

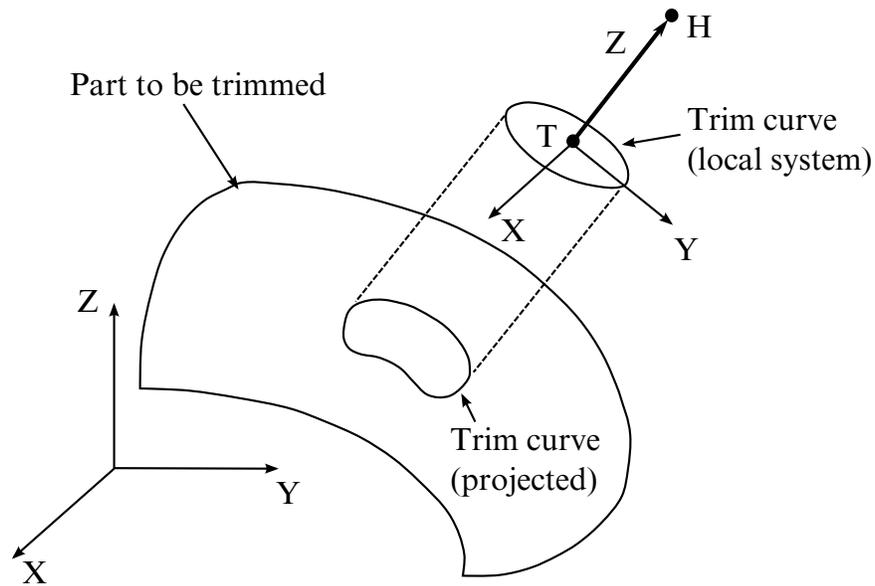

Figure 15-23. Trimming Orientation Vector. The tail (T) and head (H) points define a local coordinate system (x,y,z). The global coordinate system is named (X,Y,Z). The local x-direction is constructed in the Xz plane. If X and z nearly coincide ($|X \cdot z| > 0.95$), then the local x-direction is instead constructed in the Yz plane. Trim curve data is input in the x-y plane, and projected in the z-direction onto the deformed mesh to obtain the trim line.

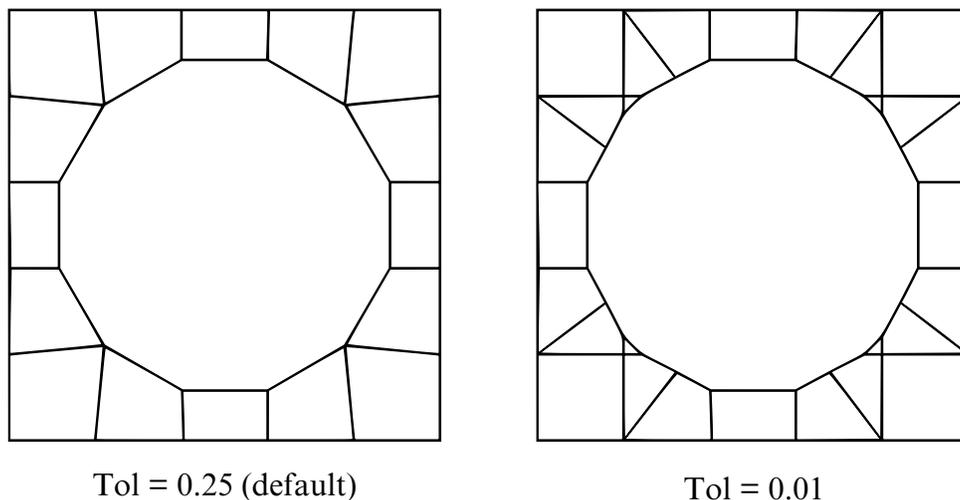

Figure 15-24. Trimming Tolerance. The tolerance limits the size of the small elements generated during trimming. The default tolerance (left) produces large elements. Using a tolerance of 0.01 (right) allows smaller elements, and more detail in the trim line.

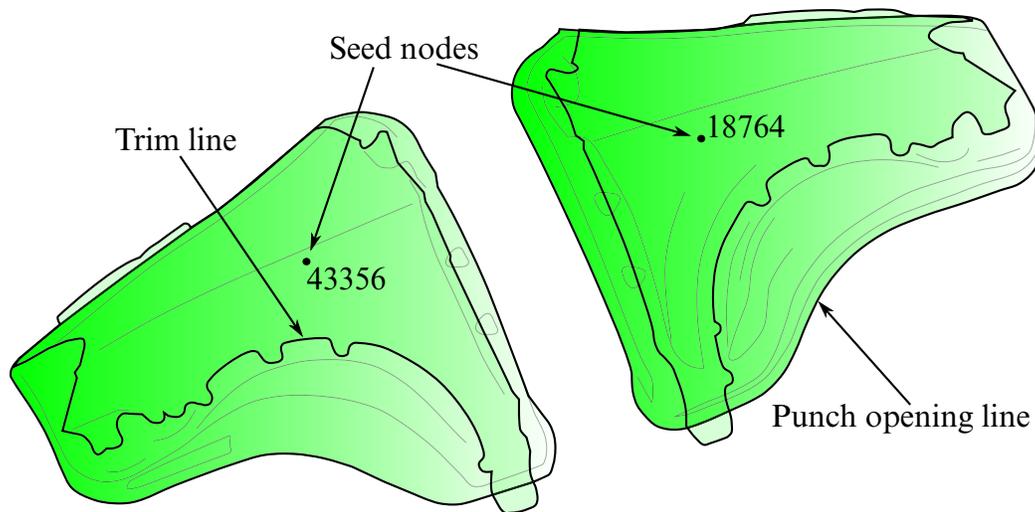

Figure 15-25. Trimming of a double-attached part (NUMISHEET2002 Fender Outer).

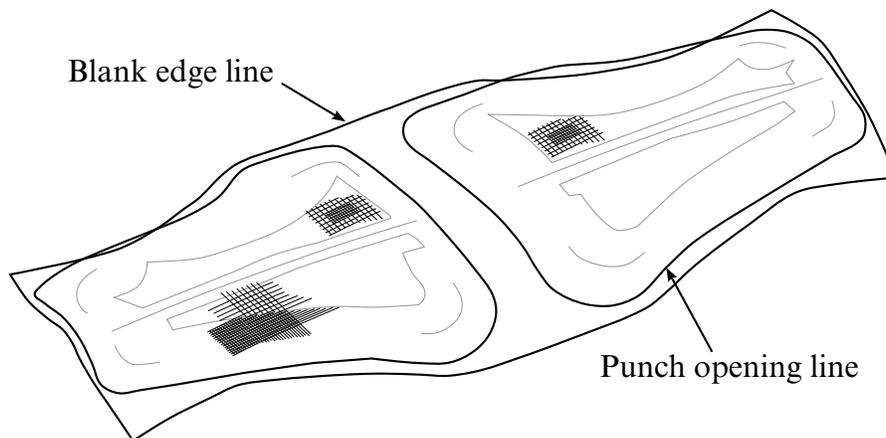

Figure 15-26. The fender outer (draw complete) in wireframe mode.

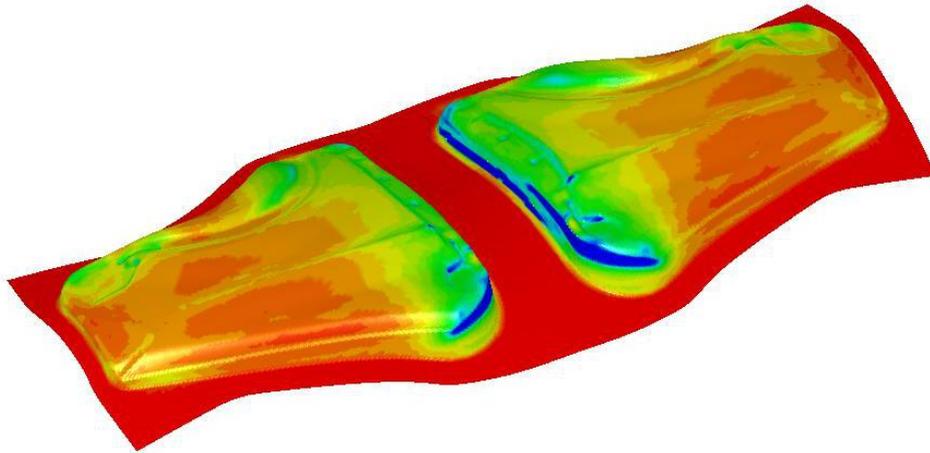

Figure 15-27. The fender outer - thickness/thinning plot on the drawn panel.

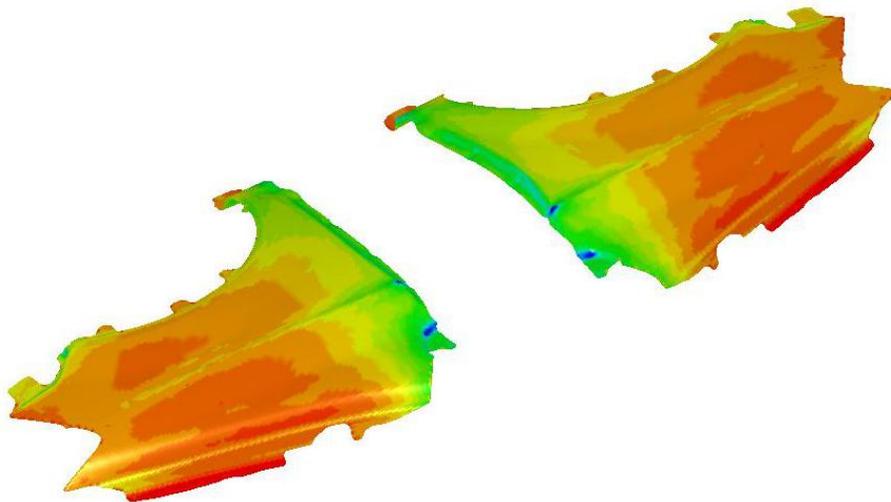

Figure 15-28. The fender outer trim complete using the NSEED1/NSEED2 feature.

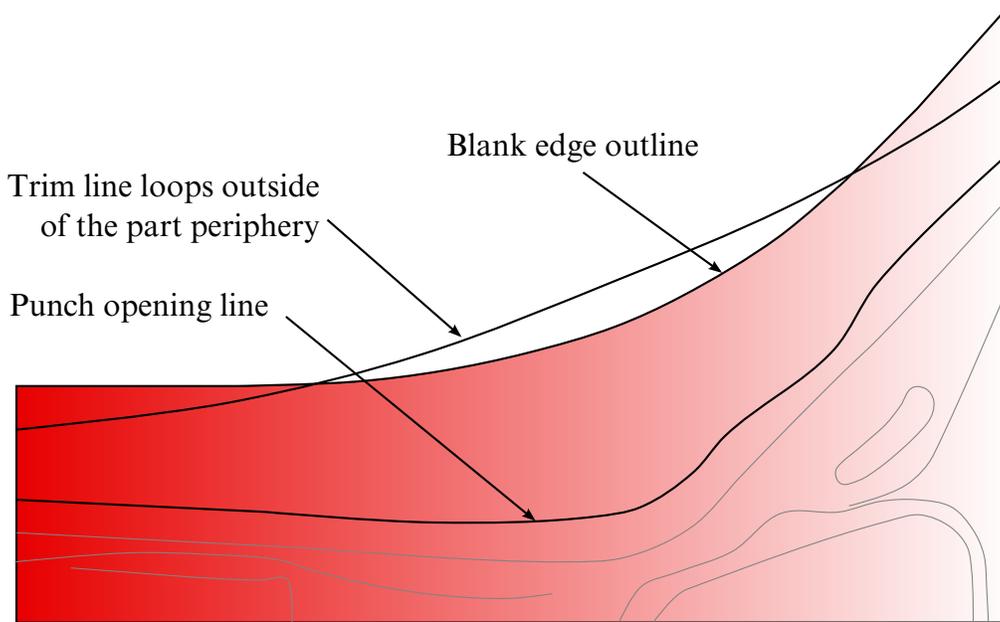

Figure 15-29. Revision 68643 deals with trim curves going beyond part boundary.

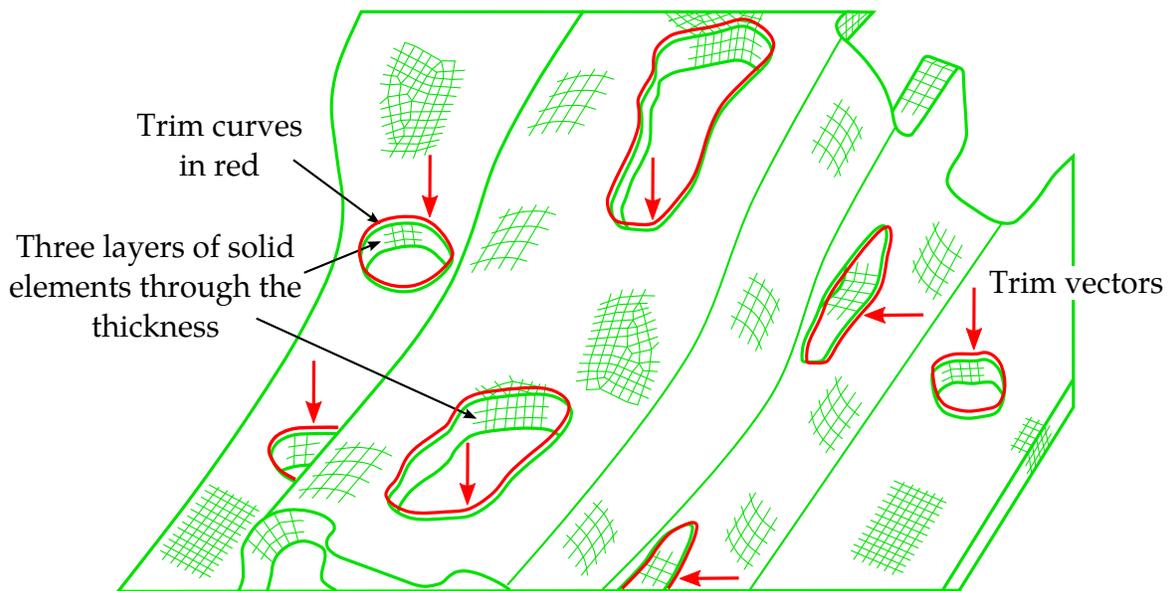

Figure 15-30. 2-D trimming of solids using *DEFINE_CURVE_TRIM_2D

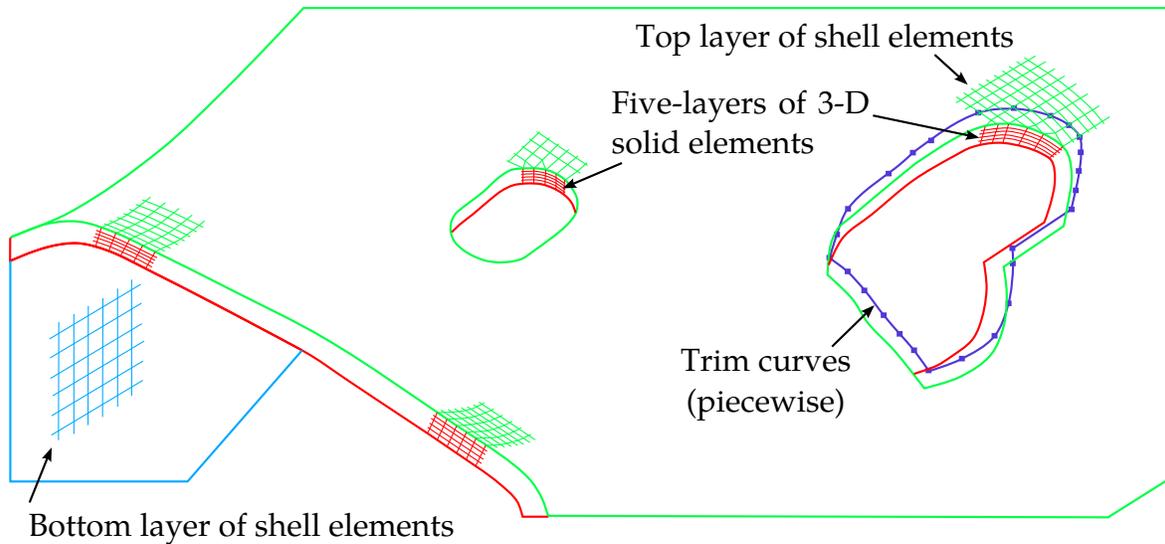

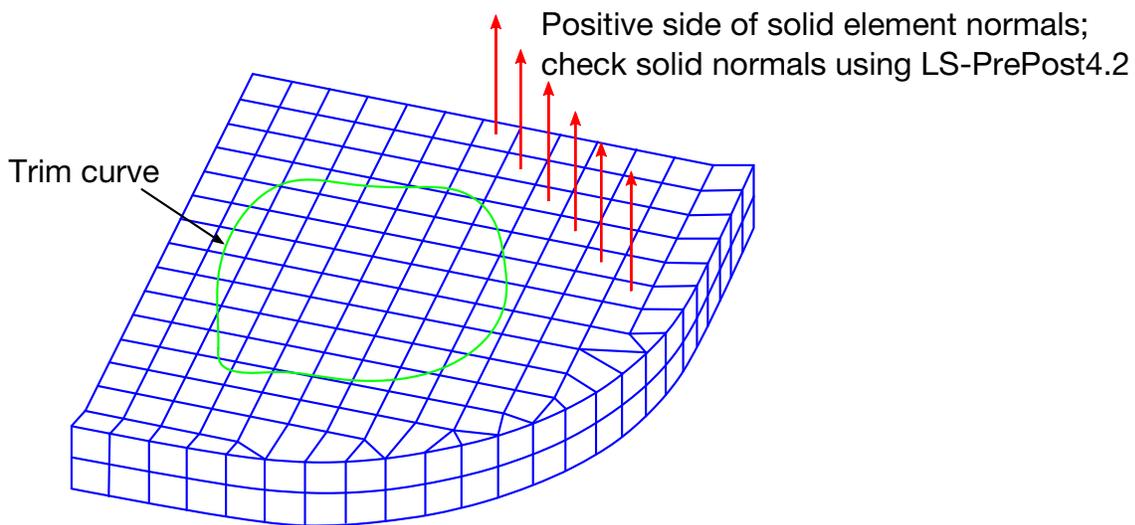

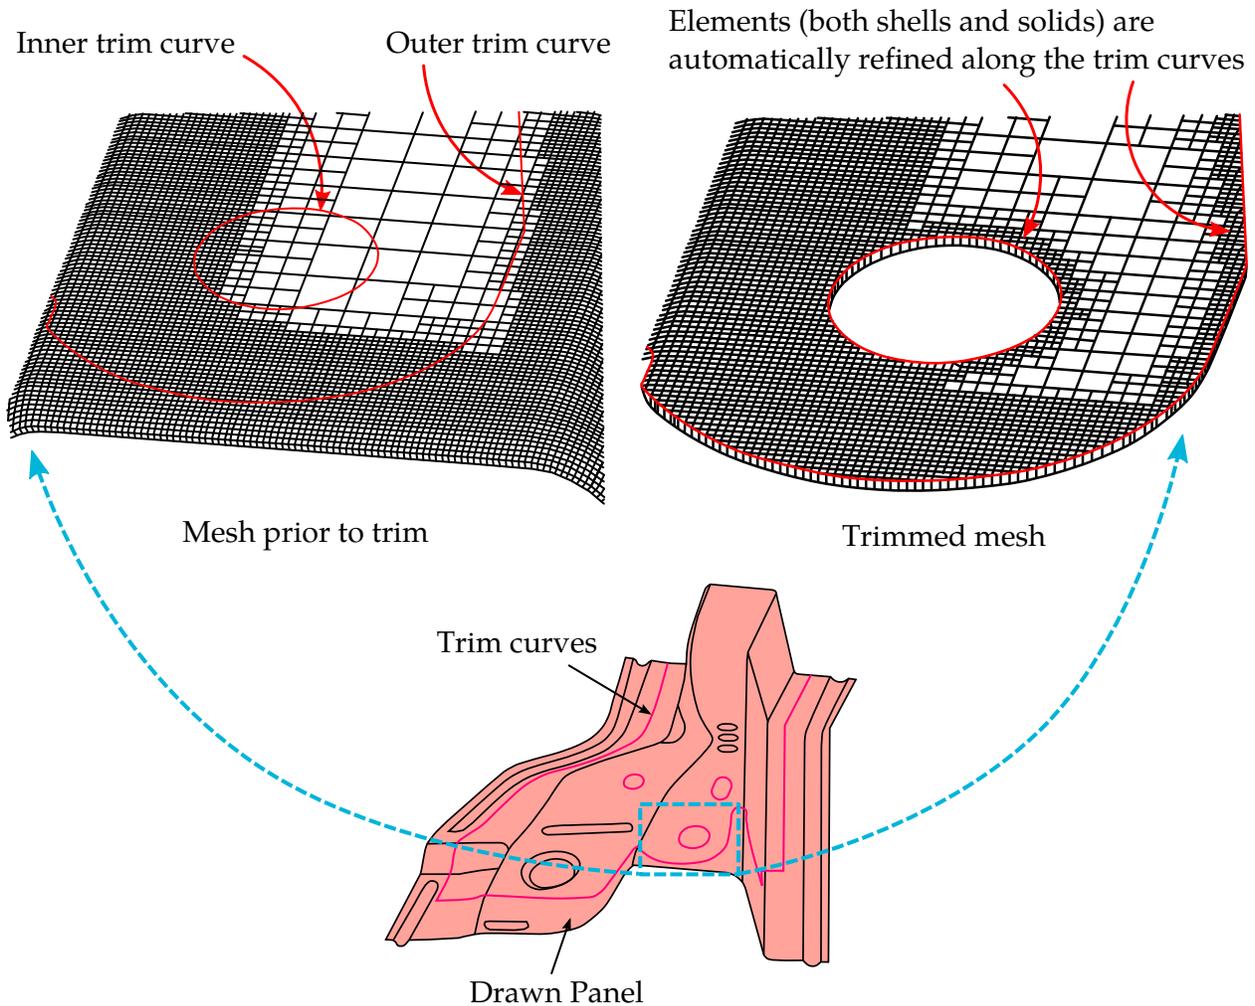

Figure 15-31. 3-D trimming of laminates (a core of multiple-layers of solid elements with top and bottom layers of shell elements) using *DEFINE_CURVE_TRIM_3D. Note that shell elements must share the same nodes with the solid elements at the top and bottom layer.

All solid element normals must be consistent. If trim curve is close to the positive normal side, set TDIR=1; otherwise set TDIR=-1. Respacing the curve with more points, project the respaced curve to the top or bottom solid surface may help the trimming.

Figure 15-32. Define trim curve for 3D trimming of solid and laminates.

2005 NUMISHEET Cross Member -
Drawn Panel and Trim Curves

Figure 15-33. Trimming of an adaptive mesh on a sandwiched part. Meshes are automatically refined along the trim curves. Note that only one layer of solid element as a core is allowed for adaptive-meshed sandwich parts. Also top and bottom layer of shells must share the same nodes as the solid elements. The keyword ***CONTROL_ADAPTIVE_CURVE** must not be used.

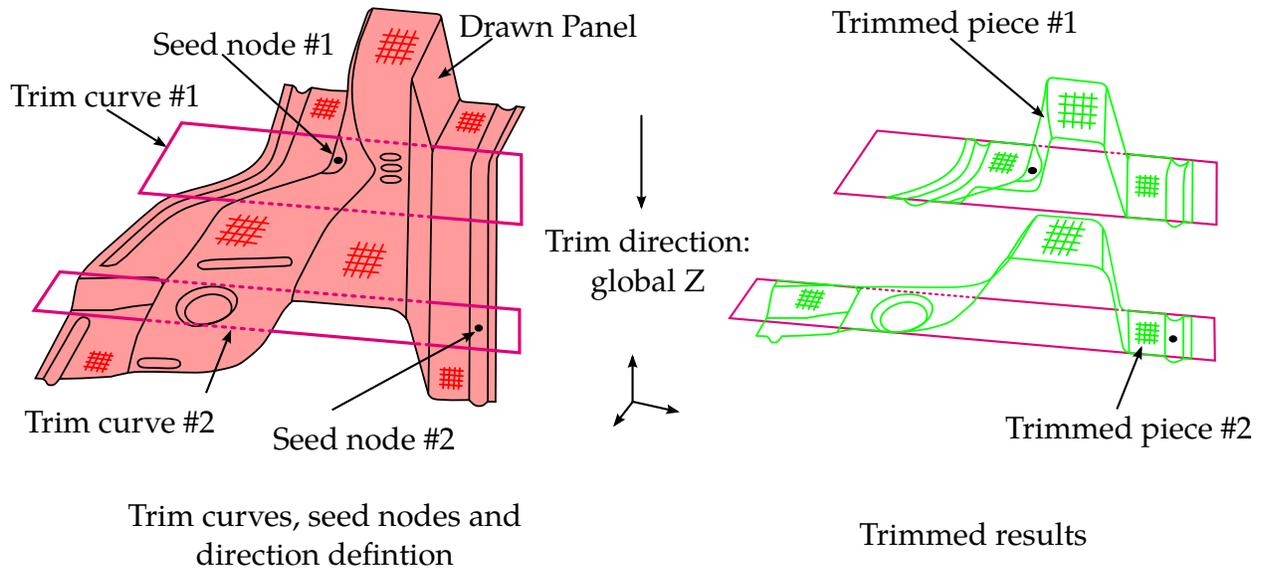

Figure 15-34. An example of 2D trimming of sandwiched part (laminates) from 2005 NUMISHEET benchmark - cross member.

*DEFINE

*DEFINE_DEATH_TIMES

*DEFINE_DEATH_TIMES_OPTION

Available options include:

NODES

SET

RIGID

Purpose: To dynamically define the death times for *BOUNDARY_PRESCRIBED_MOTION based on the locations of nodes and rigid bodies. Once a node or rigid body moves past a plane or a geometric entity, the death time is set to the current time. The input in this section continues until the next keyword ("*") card is detected.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

| Type | I | I | I | I | I | I | I | I |

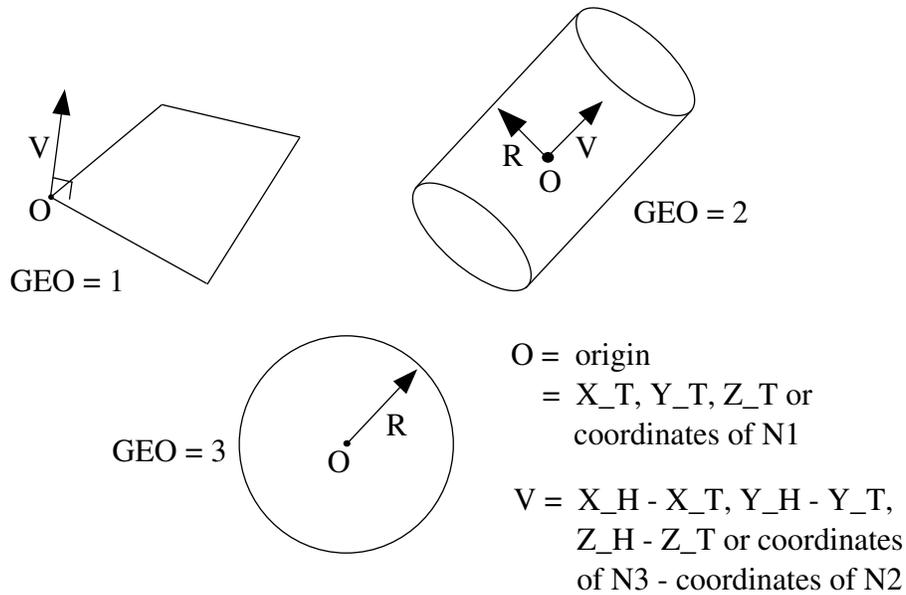

Figure 15-35. Geometry types.

| VARIABLE | DESCRIPTION |
|----------|--|
| GEO | Geometric entity type: EQ.1: plane, EQ.2: infinite cylinder, EQ.3: sphere |
| N1 | Node defining the origin of the geometric entity. See Remark 1 . |
| N2 | Node defining the tail of the orientation vector. See Remark 2 . |
| N3 | Node defining the head of the orientation vector. See Remark 2 . |
| X_T | x -coordinate of the origin of the geometric entity and the tail of the orientation vector. See Remark 1 . |
| Y_T | y -coordinate of the origin of the geometric entity and the tail of the orientation vector. See Remark 1 . |
| Z_T | z -coordinate of the origin of the geometric entity and the tail of the orientation vector. See Remark 1 . |
| X_H | x -coordinate of the head of the orientation vector. See Remark 2 . |
| Y_H | y -coordinate of the head of the orientation vector. See Remark 2 . |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| Z_H | z-coordinate of the head of the orientation vector. See Remark 2 . |
| R | Radius of cylinder or sphere. |
| FLAG | Flag for where the node or rigid body must be with respect to the geometric entity for the death time to be set to the current time: EQ.1: the node or rigid body is outside of the geometric entity or on the positive side of the plane as defined by the normal direction, EQ.-1: node or rigid body is inside the geometric entity or on the negative side of the plane |
| NSIDi | i-th node, node set, or rigid body |

Remarks:

1. **Origin.** Either N1 or X_T, Y_T, and Z_T should be specified, but not both.
2. **Orientation Vector.** Either N2 and N3 or X_H, Y_H, and Z_H should be specified, but not both. Specifying N2 and N3 is equivalent to setting the head of the vector equal to the tail of the vector (X_T, Y_T, Z_T) plus the vector from N2 to N3.

***DEFINE_DE_ACTIVE_REGION**

Purpose: To define an interested region for Discrete Elements (DE) for high efficiency collision pair searching. Any DE leaving this domain will not be considered in the future DE searching and also disabled in the contact algorithm.

VARIABLE

DESCRIPTION

PBN Parallel-bond modulus [Pa]. See Remark 1

| VARIABLE | DESCRIPTION |
|-----------------|--|
| PBS | Parallel-bond stiffness ratio. shear stiffness/normal stiffness. See Remark 2 |
| PBN_S | Parallel-bond maximum normal stress. A zero value defines an infinite maximum normal stress. |
| PBS_S | Parallel-bond maximum shear stress. A zero value defines an infinite maximum shear stress. |
| SFA | Bond radius multiplier |
| ALPHA | Numerical damping |
| MAXGAP | Maximum gap between two bonded spheres GT.0.0: defines the ratio of the smaller radius of two bonded spheres as the maximum gap, i.e. $MAXGAP \times \min(r1,r2)$ LT.0.0: absolute value is used as the maximum gap. |

Remarks:

1.The normal force is calculated as

$$\Delta f_n = \frac{PBN}{(r_0 + r_1)} \times A \times \Delta u_n$$

where

$$A = \pi r_{eff}^2$$

$$r_{eff} = \min(r_0, r_1) \times SFA$$

2.The shear force is calculated as

$$\Delta f_s = PBS \times \frac{PBN}{(r_0 + r_1)} \times A \times \Delta u_s$$

*DEFINE

*DEFINE_DE_BY_PART

*DEFINE_DE_BY_PART

Purpose: To define control parameters for discrete element sphere by part ID. This card overrides the values set in *CONTROL_DISCRETE_ELEMENT.

DESCRIPTION

| | |
|-------|--------------------------------|
| PID | Part ID of DES nodes |
| NDAMP | Normal damping coefficient |
| TDAMP | Tangential damping coefficient |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| FRICS | Static coefficient of friction (see Remarks): EQ.0.0: 3 DOF NE.0.0: 6 DOF (consider rotational DOF) |
| FRICR | Rolling friction coefficient |
| NORMK | Optional scale factor of normal spring constant (Default = 0.01) |
| SHEARK | Optional ratio between SHEARK/NORMK (Default = 2/7) |
| GAMMA | Liquid surface tension |
| VOL | Volume fraction |
| ANG | Contact angle |
| LNORM | Load curve ID of a curve that defines normal stiffness as a function of norm penetration ratio |
| LSHEAR | Load curve ID of a curve that defines shear stiffness as a function of norm penetration ratio |
| FRICD | Dynamic coefficient of friction. By default, FRICD = FRICS. See Remarks . |
| DC | Exponential decay coefficient. See Remarks . |

Remarks:

The frictional coefficient is assumed to be dependent on the relative velocity v_{rel} of the two DEM in contact

$$\mu_c = \text{FRICD} + (\text{FRICS} - \text{FRICD})e^{-\text{DC} \times |v_{rel}|}$$

***DEFINE_DE_HBOND**

Purpose: To define a heterogeneous bond model for discrete element sphere (DES).

Card Summary:

Card 1. This card is required

| | | | | | | | |
|-----|-------|-------|------|--|--|--|--|
| SID | STYPE | HBDFM | IDIM | | | | |
|-----|-------|-------|------|--|--|--|--|

Card 1.1. This card is included if and only if HBDFM = 2.

| | | | | | | | |
|--------|--------|------|------|-------|-------|-----|-------|
| PBK_SF | PBS_SF | FRGK | FRGS | BONDR | ALPHA | DMG | FRMDL |
|--------|--------|------|------|-------|-------|-----|-------|

Card 2. This card is optional.

| | | | | | | | |

VARIABLE**DESCRIPTION**

SID

DES nodes

STYPE

Set type for SID:

EQ.0: DES node set

EQ.1: DES node

EQ.2: DES part set

EQ.3: DES part

| VARIABLE | DESCRIPTION |
|----------|---|
| HBDFM | Bond formulation: EQ.1: (Reserved) EQ.2: Nonlinear heterogeneous bond formulation for fracture analysis based on the general material models defined in the material cards. DES elements with different material models can be defined within one bond. |
| IDIM | Space dimension for DES bonds: EQ.2: for 2D plane strain problems EQ.3: for 3D problems. |

Nonlinear Heterogeneous Bond Card. Include this card if and only if HBDFM = 2.

| Card 1.1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|------|------|-------|-------|-----|-------|
| Variable | PBK_SF | PBS_SF | FRGK | FRGS | BONDR | ALPHA | DMG | FRMDL |
| Type | F | F | F | F | F | F | F | I |
| Default | 1.0 | 1.0 | none | none | none | 0.0 | 1.0 | 1 |

| VARIABLE | DESCRIPTION |
|----------|--|
| PBK_SF | Scale factor for volumetric stiffness of the bond. |
| PBS_SF | Scale factor for shear stiffness of the bond. |
| FRGK | Critical fracture energy release rate for volumetric deformation due to the hydrostatic pressure. EQ.0: A zero value specifies an infinite energy release rate for unbreakable bonds. LT.0: A negative value defines the energy release rate under volumetric compression (i.e. positive pressure) and FRGS defined below is used under volumetric expansion (i.e. negative pressure). |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| FRGS | <p>Critical fracture energy release rate for shear deformation.</p> <p>EQ.0: A zero value specifies an infinite energy release rate for unbreakable bonds.</p> <p>FRGK.LT.0: See description for FRGK.</p> |
| BONDR | Influence radius of the DES nodes. |
| ALPHA | Numerical damping |
| DMG | <p>Continuous parameter for damage model.</p> <p>EQ.1.0: The bond breaks if the fracture energy in the bond reaches the critical value. Microdamage is not calculated.</p> <p>$\in (0.5,1.0)$: Microdamage effects being once the fracture energy reaches $DMG \times FMG[K,S]$. Upon the onset of microdamage, the computed damage ratio will increase (monotonically) as the fracture energy grows. Bond weakening from microdamage is modeled by reducing the bond stiffness in proportion to the damage ratio.</p> |
| FRMDL | <p>Fracture model:</p> <p>EQ.1: Fracture energy of shear deformation is calculated based on deviatoric stresses.</p> <p>EQ.2: Fracture energy of shear deformation is calculated based on deviatoric stresses, <i>excluding the axial component (along the bond)</i>.</p> <p>EQ.3,4: Same as 1&2, respectively, but FRGK and FRGS are read as the total failure energy density and will be converted to the corresponding critical fracture energy release rate. The total failure energy density is calculated as the total area under uniaxial tension stress-strain curve.</p> <p>EQ.5,6: Same as 3&4, respectively, as FRGK and FRGS are read as the total failure energy density but will not be converted. Instead, the failure energy within the bond will be calculated.</p> |

VARIABLE

DESCRIPTION

Models 1&2 are more suitable for brittle materials, and Models 5&6 are easier for ductile materials. Models 3&4 can be used for moderately ductile fracture accordingly.

This is the default fracture model applied to all DES parts, even if they have different material models. More fracture models can be defined for different materials by specifying an interface ID (ITFID) in the optional card.

Pre-Crack Card. This card is optional.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|---|-------|---|---|---|---|
| Variable | PRECRK | CKTYPE | | ITFID | | | | |
| Type | I | I | | I | | | | |
| Default | none | 0 | | 0 | | | | |

VARIABLE

DESCRIPTION

PRECRK Shell set, define 3D surfaces of the pre-crack

CKTYPE EQ.0: Part set
EQ.1: Part

ITFID ID of the interface *INTERFACE_DE_HBOND, which defines different failure models for the heterogeneous bonds within each part and between two parts respectively.

***DEFINE_DE_INJECT_BONDED {OPTION}**

Available options include:

<BLANK>

ELLIPSE

Purpose: This keyword injects bonded discrete element spheres (DES) from a specified region at a flow rate given by a user defined curve. Like *DEFINE_DE_INJECTION, when the option is blank, the region from which the DES emanate is assumed rectangular; the ELLIPSE option indicates that the region is elliptical. The first two cards are very similar to *DEFINE_DE_INJECTION. In contrast to *DEFINE_DE_INJECTION, this keyword contains additional cards to inject the bonded patterns. The bond properties of Card 3 are the same as the properties of Card 2 in *DEFINE_DE_BOND. In conjunction with the keyword *DEFINE_DE_INJECT_SHAPE, this keyword randomly selects different shape patterns and injects them at the mass flow rate (RMASS) defined in Card 2.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-----|-----|-----|-----|-----|-----|

|----------|--------|--|--|--|--|--|--|--|
| Variable | NSHAPE | | | | | | | |
| Type | I | | | | | | | |
| Default | 0 | | | | | | | |

Bonded Shape Patterns. Additional cards for NSHAPE \neq 0. Define NSHAPE patterns, requiring Ceil(NSHAPE/8) cards.

| Card 5 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|--------|--------|--------|--------|--------|--------|
| Variable | ISHAPE |
| Type | I | I | I | I | I | I | I | I |
| Default | none |

VARIABLE**DESCRIPTION**

PID Part ID of new generated DES nodes

SID Node set ID. Nodes and DES properties are generated automatically during input phase based on the user input and assigned to this SID.

XC, YC, ZC x, y, z coordinates of the center of injection plane

| VARIABLE | DESCRIPTION |
|-----------------|--|
| XL | For rectangular planes XL specifies the planar length along the x -axis in the coordinate system specified by CID. For elliptical planes XL specifies the length of the major axis. |
| YL | For rectangular planes YL specifies the planar length along the y -axis in the coordinate system specified by CID. For elliptical planes YL specifies the length of the minor axis. |
| CID | Optional local coordinate system ID, see *DEFINE_COORDINATE_SYSTEM |
| RMASS | Mass flow rate GE.0.0: constant mass flow rate LT.0.0: RMASS is a Curve ID defining the mass flow rate as a function of time |
| VX, VY, VZ | Vector components defining the initial velocity of injected DES specified relative the coordinate system defined by CID. |
| TBEG | Birth time; time for injection to begin |
| TEND | Death time; time for injection to end |
| PBN | Parallel-bond modulus [Pa]. |
| PBS | Parallel-bond stiffness ratio. Shear stiffness/normal stiffness. |
| PBN_S | Parallel-bond maximum normal stress. A zero value defines an infinite maximum normal stress. |
| PBS_S | Parallel-bond maximum shear stress. A zero value defines an infinite maximum shear stress. |
| SFA | Bond radius multiplier. |
| ALPHA | Numerical damping. |
| MAXGAP | Maximum gap between two bonded spheres GT.0.0: When MAXGAP is positive, the maximum allowed gap is determined on a bond-by-bond basis as a function of the radii of the two involved spheres. The maximum gap is determined by multiplying the minimum of the two radii by the value of MAXGAP. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | LT.0.0: absolute value is used as the maximum gap. |
| NSHAPE | Number of shape patterns. |
| ISHAPE | The pattern ID defined in *DEFINE_DE_INJECT_SHAPE. Only the first NSHAPE number of IDs will be used. |

***DEFINE_DE_INJECT_SHAPE**

Purpose: Define the bonded shape patterns. When used with *DEFINE_DE_INJECT_-BONDED, these shape patterns will be injected with equal probability. Each pattern contains several DEs, and the pattern can be in any direction. The relative positions and radii of DEs should be calculated correctly in order to generate bonds between the neighboring DEs; see the field MAXGAP in *DEFINE_DE_INJECTED_BONDED.

Card Sets: Include as many sets of Cards 1 and 2 as desired. Each set defines one shape pattern. This input terminates at the next keyword (“*”) card.

| Card 1 | 1 | 2 | | | | | | |
|----------|------|------|--|--|--|--|--|--|
| Variable | ID | NDE | | | | | | |
| Type | I | I | | | | | | |
| Default | none | none | | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | | | | |
|----------|------|------|------|------|--|--|--|--|
| Variable | X | Y | Z | R | | | | |
| Type | F | F | F | F | | | | |
| Default | none | none | none | none | | | | |

VARIABLE**DESCRIPTION**

| | |
|---------|---|
| ID | The ID of the shape pattern. |
| NDE | Number of DEs in this pattern. |
| X, Y, Z | Coordinates of the DEs in this pattern. |
| R | Radii of the DEs in this pattern. |

***DEFINE_DE_INJECTION {OPTION}**

Available options include:

<BLANK>

ELLIPSE

Purpose: This keyword injects discrete element spheres (DES) from specified a region at a flow rate given by a user defined curve. When the option is blank, the region from which the DES emanate is assumed rectangular. The elliptical option indicates that the region is to be elliptical.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-----|-----|-----|-----|-----|-----|
| Variable | PID | SID | XC | YC | ZC | XL | YL | CID |
| Type | I | I | F | F | F | F | F | I |
| Default | none | none | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0 |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|------|--------|-----|-----|-----|------|------------------|
| Variable | RMASS | RMIN | RMAX_S | VX | VY | VZ | TBEG | TEND |
| Type | F | F | F | F | F | F | F | F |
| Default | none | none | RMIN | 0.0 | 0.0 | 0.0 | 0.0 | 10 ²⁰ |

Optional card.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|---|---|---|---|---|---|
| Variable | IFUNC | | | | | | | |
| Type | I | | | | | | | |
| Default | 0 | | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| PID | Part ID of new generated DES nodes |
| SID | Node set ID. Nodes and DES properties are generated automatically during input phase based on the user input and assigned to this SID. |
| XC, YC, ZC | x, y, z coordinate of the center of injection plane |
| XL | For rectangular planes XL specifies the planar length along the x -axis in the coordinate system specified by CID. For elliptical planes XL specifies the length of the major axis. |
| YL | For rectangular planes YL specifies the planar length along the y -axis in the coordinate system specified by CID. For elliptical planes YL specifies the length of the minor axis. |
| CID | Optional local coordinate system ID; see *DEFINE_COORDINATE_SYSTEM |
| RMASS | Mass flow rate LT.0: Curve ID |
| RMIN | Minimum DES radius |
| RMAX | Maximum DES radius |
| VX, VY, VZ | Vector components defining the initial velocity of injected DES specified relative the coordinate system defined by CID. |
| TBEG | Birth time |
| TEND | Death time |
| IFUNC | EQ.0: Uniform distribution(Default) EQ.1: Gaussian distribution (see Remarks) |

Remarks:

The distribution of particle radius follows Gaussian distribution

$$f(r|r_0, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(r-r_0)^2}{2\sigma^2}},$$

where the mean radius is given by

$$r_0 = \frac{1}{2}(r_{\max} + r_{\min})$$

and the standard deviation is

$$\sigma = \frac{1}{2}(r_{\max} - r_{\min}) .$$

*DEFINE

*DEFINE_DE_MASSFLOW_PLANE

*DEFINE_DE_MASSFLOW_PLANE

Purpose: To measure DES mass flow rate across a defined plane. See also the accompanying keyword *DATABASE_DEMASSFLOW which controls the output frequency.

VARIABLE**DESCRIPTION**

SLAVE Node set ID, node ID, part set ID or part ID defining DES on slave side. STYPE below indicates the ID type specified by SLAVE.

MASTER Part set ID or part ID defining master surface. MTYPE below indicates the ID type specified by MASTER.

STYPE
 EQ.0: Slave node set
 EQ.1: Slave node
 EQ.2: Slave part set
 EQ.3: Slave part

MTYPE
 EQ.0: Part set
 EQ.1: Part

FricS Friction coefficient

FricD Rolling friction coefficient

DAMP Damping coefficient (unitless). If a discrete element sphere impacts a rigid surface with a velocity v_{impact} , the rebound velocity is

$$v_{\text{rebound}} = (1 - \text{DAMP})v_{\text{impact}}$$

| VARIABLE | DESCRIPTION |
|----------|--|
| BSORT | <p>Number of cycle between bucket sorts; default value is 100. For blast simulation with very high DEM particles velocity, it is suggested to set BSORT = 20 or smaller.</p> <p>LT.0: BSORT is the minimum number of cycle between bucket sorts. This value can be increased during runtime by tracking the velocity of potential coupling pair. This feature only works with MPP currently.</p> |
| LVCx | Load curve defines surface velocity in x -direction |
| LVCy | Load curve defines surface velocity in y -direction |
| LVCz | Load curve defines surface velocity in z -direction |
| WEARC | <p>WEARC is the wear coefficient.</p> <p>GT.0: Archard's Wear Law, See Remark 1.</p> <p>EQ.-1: Finnie Wear Law, additional card is required</p> <p>EQ.-100: User defined wear model, additional card is required</p> |
| W1-W8 | <p>For WEARC = -1, W1 is yield stress of target material</p> <p>For WEARC = -100, user defined wear parameters</p> |
| SFP | <p>Scale factor on contact stiffness. By default, SFP = 1.0. The contact stiffness is calculated as</p> $K_n = \text{SFP} \times \begin{cases} K \times r \times \text{NormK} & \text{if NormK} > 0 \\ \text{NormK} & \text{if NormK} < 0 \end{cases}$ <p>where K is bulk modulus, r is discrete element radius, NormK is the scale factor of the spring constant defined in *CONTROL_-DISCRETE_ELEMENT.</p> |
| SFT | Scale factor for surface thickness (scales true thickness). This option applies only to contact with shell elements. True thickness is the element thickness of the shell elements. |
| CID_RCF | Coordinate system ID. Force resultants are output to the demforc file in a local system. |
| BT | Birth time. |
| DT | Death time. |

Remarks:

1. **Archard's Wear Law.** If WEARC > 0, then the wear on the shell surface is calculated using Archard's wear law

$$\dot{h} = \frac{\text{WEARC} \times f_n \times v_t}{A}$$

where,

$$\begin{aligned} h &= \text{wear depth} \\ f_n &= \text{normal contact force from DE} \\ v_t &= \text{tangential sliding velocity of the DE on shell} \\ A &= \text{area of contact segment} \end{aligned}$$

The wear depth is output to the interface force file.

2. **Finnie's Wear Law.** If WEARC = -1, then the wear on the shell surface is calculated using Finnie's wear law. The model of Finnie relates the rate of wear to the rate of kinetic energy of particle impact on a surface as:

$$Q = \begin{cases} \frac{mv^2}{8p} (\sin 2\alpha - 3 \sin^2 \alpha) & \text{if } \tan \alpha < \frac{1}{3} \\ \frac{mv^2}{24p} \cos^2 \alpha & \text{if } \tan \alpha > \frac{1}{3} \end{cases}$$

where, Q is the volume of the material removed from surface, m is particle mass, α is the impact angle, and p is the yield stress of the target material input in field W1. The wear depth is output to the interface force file.

3. **Interface Force File.** *DATABASE_BINARY_DEMFOR controls the output interval of the coupling forces to the DEM interface force file. This interface force file is activated by the command line option "dem=", for example,

lsdyna i=inputfilename.k ... dem=interfaceforce_filename

The DEM interface force file can be read into LS-PrePost for plotting of coupling pressure and forces on the master segments.

4. **Coupling Force Output.** *DATABASE_RCFORC controls the output interval of the coupling forces to the ASCII demrcf file. This output file is analogous to the rforc file for *CONTACT.

***DEFINE_DE_TO_SURFACE_TIED**

Purpose: To define a tied-with-failure coupling interface between discrete element spheres (DES) and a surface defined by shell part(s) or solid part(s). This coupling is currently not implemented for tshell part(s).

| | | | | | | | | |
|----------|-------|--------|-------|-------|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | SLAVE | MASTER | STYPE | MTYPE | | | | |

| Default | 0 | 0 | 0 | 0 | | | | |

| | | | | | | | | |
|----------|----------|----------|-----|-----|------|-------|---|---|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | NFLF | SFLF | NEN | MES | LCID | NSORT | | |
| Type | F | F | F | F | I | I | | |
| Default | Required | Required | 2. | 2. | 0 | 100 | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| SLAVE | Node set ID, node ID, part set ID or part ID defining DES on slave side. STYPE below indicates the ID type specified by SLAVE. |
| MASTER | Part set ID or part ID defining master surface. MTYPE below indicates the ID type specified by MASTER. |
| STYPE | EQ.0: Slave node set EQ.1: Slave node EQ.2: Slave part set EQ.3: Slave part |
| MTYPE | EQ.0: Part set EQ.1: Part |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| NFLF | Normal failure force. Only tensile failure, i.e., tensile normal forces, will be considered in the failure criterion |
| SFLF | Shear failure force |
| NEN | Exponent for normal force |
| MES | Exponent for shear force. Failure criterion: $\left(\frac{ f_n }{\text{NFLF}}\right)^{\text{NEN}} + \left(\frac{ f_s }{\text{SFLF}}\right)^{\text{MES}} \geq 1.$ Failure is assumed if the left side is larger than 1. f_n and f_s are the normal and shear interface force. |
| LCID | Optional curve ID defining a scale factor vs. time. The scale factor is applied to NFLF and SFLF, making the failure forces time-dependent. |
| NSORT | Number of cycle between bucket sort |

Remarks:

Both NFLF and SFLF must be defined. If failure in only tension or shear is required then set the other failure force to a large value (10^{10}).

*DEFINE_DRIFT_REMOVE

Purpose: Minimize the drift of a structure over a loop by modifying the curves for specifying accelerations and forces.

| | | | | | | | | |
|----------|--------|---|---|---|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | OPTION | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

Curve Card. Include as many of this card as needed. Input ends at the next keyword ("*") card.

| | | | | | | | | |
|----------|-----|-----|-----|-----|-----|-----|-----|-----|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | ID1 | ID2 | ID3 | ID4 | ID5 | ID6 | ID7 | ID8 |
| Type | I | I | I | I | I | I | I | I |

| VARIABLE | DESCRIPTION |
|----------|--|
| OPTION | Specifies how curves are handled. EQ.0: no changes are made to the curves. EQ.1: modify to minimize the drift. |
| ID[N] | ID of N th curve to be modified |

Remarks:

When data from an accelerometer is integrated to obtain velocities and displacements numerical noise leads to drift. For signals that are necessarily periodic, like data collected as a car drives around a track, the resulting quadrature loses its periodicity. This keyword activates an algorithm that approximately restores periodicity.

Because its chief property is *not* being periodic we approximate noise, a_{noise} , by a function that is not periodic, namely, a parabola (or possibly a straight line)

$$a_{noise}(t) = a_0 + a_1t + a_2t^2 .$$

Since a_{noise} cannot be allowed in the context of periodicity we seek to find an $a_{\text{corrected}}$

$$a_{\text{corrected}} = a_{\text{data}} - a_{\text{noise}}$$

that removes as much “noise” as possible. We therefore find the a_i that minimize the norm of the corrected velocity,

$$\int_{t_0}^{t_1} [v_{\text{corrected}}(t)]^2 dt ,$$

where the corrected velocity is the quadrature of the corrected noise,

$$v_{\text{corrected}}(t) = \int_{t_0}^t [a_{\text{data}}(\tau) - a_{\text{noise}}(\tau)] d\tau = v_{\text{data}}(t) - \left(a_0 t + \frac{1}{2} a_1 t^2 + \frac{1}{3} a_2 t^3 \right) .$$

For each curve listed on the data cards LS-DYNA approximately removes the drift by numerically solving the above minimization problem.

***DEFINE_ELEMENT_DEATH_OPTION**

Available options include:

- SOLID
- SOLID_SET
- BEAM
- BEAM_SET
- SHELL
- SHELL_SET
- THICK_SHELL
- THICK_SHELL_SET

Purpose: Defines a discrete time or box to delete an element or element set during the simulation. This keyword is only for deformable elements, not rigid body elements.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---------|------|-------|-------|-------|-----------|---------|---|
| Variable | EID/SID | TIME | BOXID | INOUT | IDGRP | CID | PERCENT | |
| Type | I | F | I | I | I | I | F | |
| Default | none | 0.0 | {Ø} | 0 | 0 | see below | 0.0 | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| EID/SID | Element ID or element set ID identifying elements that are considered for deletion, either by meeting the BOXID/INOUT criterion or the independent TIME/IDGRP/PERCENT criterion. |
| TIME | Deletion time for elimination of the element or element set. If BOXID is nonzero, a TIME value of zero is reset to 1.0E+16. |
| BOXID | An optional box ID; see CID below and *DEFINE_BOX. Element(s) are immediately deleted upon meeting the condition of being inside the box (or outside the box, depending on INOUT), without regard to TIME, IDGRP, or PERCENT. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| INOUT | Flag pertaining to BOXID EQ.0: Elements inside the box EQ.1: Elements outside the box |
| IDGRP | Group ID. Elements sharing the same positive value of IDGRP are considered to be in the same group. All elements in a group will be simultaneously deleted one cycle after a percentage of the elements (specified in PERCENT) fail. There is no requirement that each *DEFINE_ELEMENT_DEATH command have a unique IDGRP. In other words, elements in a single group can come from multiple *DEFINE_ELEMENT_DEATH commands. Elements in which IDGRP = 0 are not assigned to a group and thus deletion of one element does not cause deletion of the other elements. |
| CID | Coordinate ID for transforming box BOXID. If CID is not specified, the box is in the global coordinate system. The box rotates and translates with the coordinate system only if the coordinate system is flagged for an update every time step. |
| PERCENT | Deletion percentage. EQ.0.0: When one element fails, all elements in the group will be deleted (default). GT.0.0: Percentage of elements failed before elements in group IDGRP are deleted. |

***DEFINE_ELEMENT_GENERALIZED_SHELL**

Purpose: Define a general 3D shell formulation to be used in combination with *ELEMENT_GENERALIZED_SHELL. The objective of this feature is to allow the rapid prototyping of new shell element formulations by adding them through the keyword input file.

All necessary information, like the values of the shape functions and their derivatives at various locations (at the integration points and at the nodal points), must be defined using this keyword. An example for a 9-noded generalized shell element with 4 integration points in the plane is given in Figure 15-36 to illustrate the procedure. The element formulation ID (called ELFORM) used in this keyword needs to be greater or equal than 1000 and will be referenced through *SECTION_SHELL (see Figure 17-3 in *ELEMENT_GENERALIZED_SHELL).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|------|------|-------|------|---|---|---|
| Variable | ELFORM | NIPP | NMNP | IMASS | FORM | | | |
| Type | I | I | I | I | I | | | |
| Default | none | none | none | none | none | | | |

Weights and Shape Function Values/Derivatives at Gauss Points:

These cards are read according to the following pseudo code:

```

for i = 1 to NIPP {
  read Card 2(i)
  for k = 1 to NMNP {
    read Card 3(i,k)
  }
} // comment: Read in NIPP x (1 + NMNP) cards

```

Weight Cards. Provide weight for integration point *i*.

| (Card 2) _{<i>i</i>} | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|------------------------------|----|---|---|---|---|---|---|---|
| Variable | WI | | | | | | | |
| Type | F | | | | | | | |

Integration Point Shape Function Value/Derivatives Cards. Provide the value of the k^{th} shape function and its derivative at the i^{th} integration point.

| (Card 3) $_{jk}$ | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|------------------|-----|---|--------|---|--------|---|---|---|
| Variable | NKI | | DNKIDR | | DNKIDS | | | |
| Type | F | | F | | F | | | |

For FORM = 0 or FORM = 1, Shape Function Derivatives at Nodes:

These cards are read according to the following pseudo code:

```

for l = 1 to NMNP {
  for k = 1 to NMNP {
    read Card 4a(l,k)
  }
} // comment: Read in NMNP x NMNP cards

```

Nodal Shape Function Derivative Cards. The value of the k^{th} shape function's derivative at the l^{th} nodal point.

| (Card 4a) $_{lk}$ | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-------------------|--------|---|--------|---|---|---|---|---|
| Variable | DNKLDR | | DNKLDS | | | | | |
| Type | F | | F | | | | | |

For FORM = 2 or FORM = 3, Shape Function 2nd derivative at Gauss Points:

NOTE: For FORM = 2 and FORM = 3 it is assumed that the shape functions are at least C1 continuous (having a continuous derivative).

The cards for this method are read according to the following pseudo code:

```

for i = 1 to NIPP {
  for k = 1 to NMNP {
    read Card 4b(i,k)
  }
} // comment: Read in NGP × NMNP cards

```

Nodal Shape Function Second Derivative Cards. The value of the k^{th} shape function's second derivative at the i^{th} integration point.

| (Card 4b) _{ik} | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-------------------------|----------|---|-----------|---|----------|---|---|---|
| Variable | D2NKIDR2 | | D2NKIDRDS | | D2NKIDS2 | | | |
| Type | F | | F | | F | | | |

VARIABLE**DESCRIPTION**

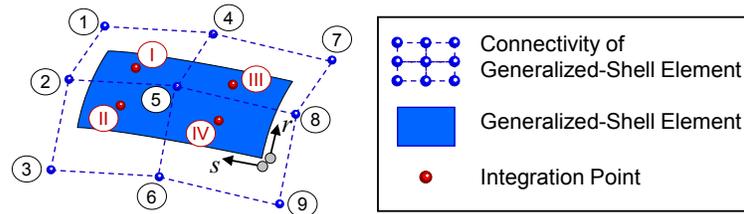

| | |
|--------|--|
| ELFORM | Element Formulation ID which is referenced by *SECTION_SHELL to connect *ELEMENT_GENERALIZED_SHELL with the appropriate shell formulation. The chosen number needs to be greater or equal than 1000. |
| NIPP | Number of in-plane integration points. |
| NMNP | Number of nodes for this element formulation. |
| IMASS | Option for lumping of mass matrix: EQ.0: row sum EQ.1: diagonal weighting. |
| FORM | Shell formulation to be used EQ.0: shear deformable shell theory with rotational DOFs (shell normal evaluated at the nodes) EQ.1: shear deformable shell theory without rotational DOFs (shell normal evaluated at the nodes) EQ.2: thin shell theory without rotational DOFs (shell normal evaluated at the integration points) EQ.3: thin shell theory with rotational DOFs (shell normal evaluated at the integration points) |
| WI | Integration weight at integration point i . |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| NKI | Value of the shape function N_k evaluated at integration point i . |
| DNKIDR | Value of the derivative of the shape function N_k with respect to the local coordinate r at the integration point i $\left(\frac{\partial N_k^i}{\partial r}\right)$. |
| DNKIDS | Value of the derivative of the shape function N_k with respect to the local coordinate s at the integration point i $\left(\frac{\partial N_k^i}{\partial s}\right)$. |
| DNKILDR | Value of the derivative of the shape function N_k with respect to the local coordinate r at the nodal point l $\left(\frac{\partial N_k^l}{\partial r}\right)$. |
| DNKILDS | Value of the derivative of the shape function N_k with respect to the local coordinate s at the nodal point l $\left(\frac{\partial N_k^l}{\partial s}\right)$. |
| D2NKIDR2 | Value of the second derivative of the shape function N_k with respect to the local coordinate r at the integration point i $\left(\frac{\partial^2 N_k^i}{\partial r^2}\right)$. |
| D2NKIDRDS | Value of the second derivative of the shape function N_k with respect to the local coordinates r and s at the integration point i $\left(\frac{\partial^2 N_k^i}{\partial r \partial s}\right)$. |
| D2NKIDS2 | Value of the second derivative of the shape function N_k with respect to the local coordinate s at the integration point i $\left(\frac{\partial^2 N_k^i}{\partial s^2}\right)$. |

Remarks:

- Interpolation Shell Elements.** For post-processing and the treatment of contact boundary conditions, the use of interpolation shell elements (see *ELEMENT_INTERPOLATION_SHELL and *CONSTRAINED_NODE_INTERPOLATION) is necessary.
- Input Order.** Data input order for the NMNP nodal points must match the definition of the connectivity of the element in *ELEMENT_GENERALIZED_SHELL.

Example:

```

Figure 15-36. Example of a generalized shell formulation with *DEFINE_ELEMENT_GENERALIZED_SHELL.

***DEFINE_ELEMENT_GENERALIZED_SOLID**

Purpose: Define a general 3D solid formulation to be used in combination with *ELEMENT_GENERALIZED_SOLID. New solid element formulations may be rapidly prototyped in the input deck using this feature.

All necessary information, like the values of the shape functions and their derivatives at all integration points, must be defined using this keyword. The example shown in [Figure 15-37](#) illustrates this procedure by prototyping an 18-noded generalized solid element with 8 integration points. The element formulation ID (called ELFORM) used in this keyword needs to be greater or equal than 1000 and will be referenced through *SECTION_SOLID (see [Figure 17-4](#) in *ELEMENT_GENERALIZED_SOLID).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|------|------|-------|---|---|---|---|
| Variable | ELFORM | NIP | NMNP | IMASS | | | | |
| Type | I | I | I | I | | | | |
| Default | none | none | none | none | | | | |

Weights and Shape Function Values/Derivative at Gauss Points:

These cards are read according to the following pseudo code:

```

for i = 1 to NIP {
  read Card 2(i)
  for k = 1 to NMNP {
    read Card 3(i,k)
  }
} // comment: Read in NIP × (1 + NMNP) cards
    
```

Weight Cards. Provide weight for integration point *i*.

| (Card 2) _{<i>i</i>} | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|------------------------------|----|---|---|---|---|---|---|---|
| Variable | WI | | | | | | | |
| Type | F | | | | | | | |

Integration Point Shape Function Value/Derivatives Cards. Provide the value of the k^{th} shape function and its derivative at the i^{th} integration point.

| (Card 3) $_{jk}$ | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|------------------|-----|---|--------|---|--------|---|--------|---|
| Variable | NKI | | DNKIDR | | DNKIDS | | DNKIDT | |
| Type | F | | F | | F | | F | |

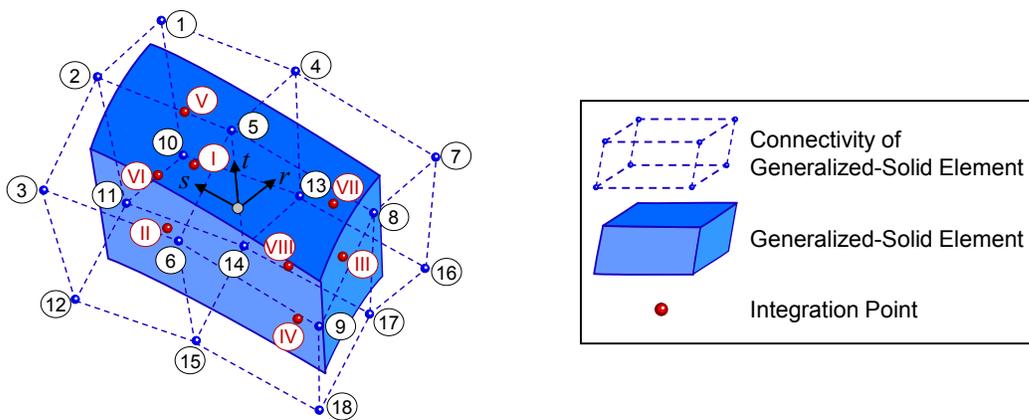

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| ELFORM | Element Formulation ID referenced by *SECTION_SOLID to connect *ELEMENT_GENERALIZED_SOLID with the appropriate solid formulation. The chosen number needs to be greater or equal than 1000. |
| NIP | Number of integration points. |
| NMNP | Number of nodes for this element formulation. |
| IMASS | Option for lumping of mass matrix: EQ.0: row sum EQ.1: diagonal weighting. |
| WI | Integration weight at integration point i . |
| NKI | Value of the shape function N_k evaluated at integration point i . |
| DNKIDR | Value of the derivative of the shape function N_k with respect to the local coordinate r at the integration point i $\left(\frac{\partial N_k^i}{\partial r}\right)$. |
| DNKIDS | Value of the derivative of the shape function N_k with respect to the local coordinate s at the integration point i $\left(\frac{\partial N_k^i}{\partial s}\right)$. |
| DNKIDT | Value of the derivative of the shape function N_k with respect to the local coordinate t at the integration point i $\left(\frac{\partial N_k^i}{\partial t}\right)$. |

Remarks:

1. **Post-Processing.** For post-processing the use of interpolation solid elements (see *ELEMENT_INTERPOLATION_SOLID and *CONSTRAINED_NODE_INTERPOLATION) is necessary.
2. **Input Order.** Data input order for the NMNP nodal points must correlate with the definition of the connectivity of the element in *ELEMENT_GENERALIZED_SOLID.

Example:

```

*DEFINE_ELEMENT_GENERALIZED_SOLID
$#  elform      nip      nmnp      imass
    1001         8        18         0

Figure 15-37. Example of a generalized solid formulation with *DEFINE_ELEMENT_GENERALIZED_SOLID

***DEFINE_FABRIC_ASSEMBLIES**

Purpose: Define lists of part sets to properly treat fabric bending between parts.

Define as many cards as needed for the assemblies, using at most 8 part sets per card. This input ends at the next keyword ("*") card.

| | | | | | | | | |
|----------|-------|-------|-------|-------|-------|-------|-------|-------|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | SPID1 | SPID2 | SPID3 | SPID4 | SPID5 | SPID6 | SPID7 | SPID8 |
| Type | I | I | I | I | I | I | I | I |
| Default | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

VARIABLE

DESCRIPTION

| | |
|-------------------|---|
| SPID _n | Part set ID that comprises an assembly. |
|-------------------|---|

Remarks:

The materials *MAT_FABRIC and *MAT_FABRIC_MAP are equipped with an optional coating feature to model the fabric's bending resistance. See the related parameters ECOAT, SCOAT and TCOAT on these material model manual entries.

The default behavior for these coatings, *which this keyword changes*, excludes T-intersections, and, furthermore requires that all fabric elements must have a consistently oriented normal vector. In [Figure 15-38](#), the left connection of fabric elements is permitted by the default functionality while the right one is not. However, with using this keyword the proper bending treatment for the right connectivity can be activated by adding the following input to the deck

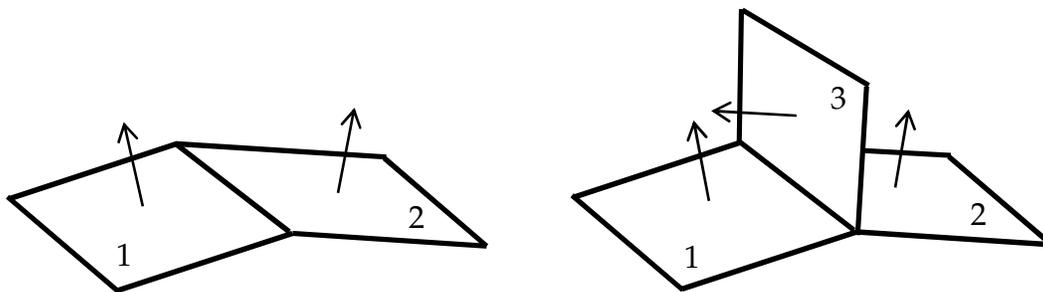

Figure 15-38. Bending in fabric, intended use of *DEFINE_FABRIC_ASSEMBLIES. The numbers indicate the parts the elements belong to.

```
*SET_PART_LIST
1
1,2
*SET_PART_LIST
2
3
*DEFINE_FABRIC_ASSEMBLIES
1,2
```

which decouples part 3 from the other two parts in terms of bending, thus creating a moment free hinge along the edge between part sets 1 and 2. Bending between parts 1 and 2 is unaffected since these are contained in the same fabric assembly.

For several instances of this keyword in an input deck, the list of assemblies is appended. If assemblies are defined and there happens to be fabric parts that do not belong to any of the specified assemblies, then these parts are collected in a separate unlisted assembly. The restriction on consistent normal vectors and on having no T-intersections applies to all elements within an assembly.

***DEFINE_FIBERS**

Purpose: This keyword defines carbon fibers and their related properties in a matrix for a one-step inverse forming simulation; therefore, it works only with the keyword *CONTROL_FORMING_ONESTEP, and double precision executable is required.

Fiber ID and Property Card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|-------|
| Variable | IDF | IDP | NUMF | N1 | N2 | EFB | SHR | HRGLS |
| Type | I | I | I | I | I | F | F/I | F |
| Default | none | 1.0 |

Fiber Orientation Card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|--------|---|---|---|---|---|
| Variable | ALPHA1 | ALPHA2 | ALPHA3 | | | | | |
| Type | F | F | F | | | | | |
| Default | none | none | none | | | | | |

Reference Fiber Orientation Card. Define this card if N1 and N2 in card 1 are undefined, or zero.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|---|---|
| Variable | X1 | Y1 | Z1 | X2 | Y2 | Z2 | | |
| Type | F | F | F | F | F | F | | |
| Default | none | none | none | none | none | none | | |

| VARIABLE | DESCRIPTION |
|------------------------------|--|
| IDF | ID of a fiber set to be defined, must be unique number, see Figure 15-39 . |
| IDP | Part ID of the matrix material associated with the fiber set, see Figure 15-39 . |
| NUMF | Number of fiber orientations, see Figure 15-39 . |
| N1, N2 | Direction from Node 1 (N1) to Node 2 (N2) defines the reference fiber orientation, see Figure 15-39 . |
| EFB | Effective stiffness of the fiber in its orientation, which typically equals to Young's Modulus times fiber cross sectional area fraction. Fiber cross sectional area fraction is typically between 0.25 and 0.5. |
| SHR | Shear stiffness of the fiber: GT.0: shear stiffness, LT.0: $ SHR $ is the load curve ID defining shear stiffness vs. shear strain. |
| HRGLS | Hourglass coefficient for stiffness type hourglass control. Default = 1.0. |
| ALPHA1, ALPHA2, ALPHA3 | Initial orientation angles of the first, second and third fibers relative to reference fiber orientation defined by N1-N2, respectively. |
| X1, Y1, Z1, X2, Y2, Z2 | If N1 and N2 are undefined, or zero, a third card is required to define the coordinates for N1 and N2. The Z1 and Z2 coordinate values must be defined close to the part. Based on the coordinate inputs, LS-DYNA will find the nearest nodes to define N1 and N2 from the model. See Figure 15-39 . |

Remarks:

1. *MAT_024 is supported to define matrix material.
2. Three nodes to re-position the blank in *CONTROL_FORMING_ONESTEP is disabled when *DEFINE_FIBERS is used. Use dynain (not repositioned.k) file for predicted flat blank.

3. Coulomb friction can be specified under *CONTROL_FORMING_ONESTEP_FRICTION, with appropriate binder tonnage.
4. Use of *CONTROL_FORMING_ONESTEP_DRAWBEAD is not recommended.
5. Element direction of the matrix must be consistent. The directions can be displayed in *LS-PrePost4.6*, under *EleTol* → *EleEdit* → *Direction* → *Shell* → *Vector* → *Apply*. To align in a part all element directions with an existing element direction, follow *EleTol* → *EleEdit* → *Direction* → *Shell* → *Orient* → *Pick seed* → *Apply*.
6. It goes without saying that it is important to use appropriate material properties for both the fibers and the matrix material.
7. For some parts, more steps may be needed for better prediction of initial blank size. DT0 under *CONTROL_IMPLICIT_GENERAL can be adjusted for additional steps.
8. Extra keywords, *ELEMENT_FIBER_INFO and *ELEMENT_BEAM (new part IDs) are automatically created in onestepresult file to display in *LS-PrePost* the fiber orientations after forming, see [Figure 15-39](#).
9. Furthermore, additional history variables are written in onestepresult file to display various angles in color contours, see [Figure 15-39](#):
 - History variable #1: the angle between two fibers,
 - History variable #2: the angle between the first fiber and the element direction,
 - History variable #3: the angle between the second fiber and the element direction.

These color contour fringe plots can be overlaid with the beam elements to verify the fiber orientations. To request history variable output, set NEIPS in *DATABASE_EXTENT_BINARY to at least a value of "3".

Application example:

A partial keyword example below defines a fiber set ID 1 in a matrix material with part ID 121, with the first and the second fiber orientations at 45° and 135°, respectively, from the reference fiber direction defined by N1 with coordinates [2650.0, 800.0, 808.0], and N2 [2940.0, 800.0, 800.0].

***DEFINE_FILTER**

Purpose: Define a general purpose filter, currently used by this option:

SENSOR_SWITCH

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|-------|---|---|---|---|---|---|
| Variable | ID | TITLE | | | | | | |
| Type | I | A70 | | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|-------|-------|-------|-------|-------|-------|
| Variable | TYPE | DATA1 | DATA2 | DATA3 | DATA4 | DATA5 | DATA6 | DATA7 |
| Type | A10 | | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|---------|---|
| ID | Identification number. |
| TITLE | Title for this filter. |
| TYPE | One of the 3 currently defined filter types: DISCRETE, CONTINUOUS, or CHAIN |
| DATA1-7 | Filter type specific data, which determines what the filter does. |

Filter Types:**FILTER****DESCRIPTION**

| | |
|----------|---|
| DISCRETE | The discrete filter operates on a fixed number of values of the input data. The first data field is an A10 character field, which gives the type of operation the filter performs: MIN, MAX, and AVG are the available options. The second data field is an I10 field, giving the number of input values over which the minimum, maximum, or average is computed. |
|----------|---|

| FILTER | DESCRIPTION |
|---------------|--|
| CONTINUOUS | Like the DISCRETE filter, except that it operates over a fixed time interval. The first data field is exactly the same as for the DISCRETE option. The second data field is an F10 field, indicating the duration of the filter. For example, if AVG is given, and the duration is set to 0.1, a running timestep weighted average is computed over the last 0.1 time of the simulation. |
| CHAIN | Here, data fields 1-7 are all I10 fields, and give the IDs of a list of other filters (including other CHAIN filters, if desired), each of which will be applied in order. So the raw data is fed to the filter indicated by DATA1. The output of that is fed to the next filter, and so on, with up to 7 filters in the chain. List only as many filters as you need. |

***DEFINE_FORMING_BLANKMESH**

Purpose: A rectangular sheet metal blank can be defined, with square elements and arbitrary mesh orientation. This blank can, then, be trimmed with *ELEMENT_BLANKING, and *DEFINE_CURVE_TRIM_2D into a developed blank with a complex periphery and inner hole cutouts. This keyword is renamed from the previous keyword *CONTROL_FORMING_BLANKMESH.

VARIABLE**DESCRIPTION**

| | |
|-------|--|
| IDMSH | An unique ID of the blank mesh (not the blank PID) to be generated. |
| ELENG | The edge length of the square element to be generated. |
| LENG1 | First edge length of the rectangular blank along the following axis in the coordinate system (CID) defined: NPLANE.EQ.1: X-axis NPLANE.EQ.2: Y-axis NPLANE.EQ.3: Z-axis |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| LENG2 | Second edge length of the rectangular blank along the following axis in the coordinate system (CID) defined. NPLANE.EQ.1: Y-axis NPLANE.EQ.2: Z-axis NPLANE.EQ.3: X-axis |
| ANGLE | An angle about the following axis of the CID defined, starting from its respective axis, to rotate the blank (the orientation of the mesh) to be generated. The sign of the rotation angle follows the right-hand rule. NPLANE.EQ.1: about Z-axis, starting from the positive X-axis NPLANE.EQ.2: about X-axis, starting from the positive Y-axis NPLANE.EQ.3: about Y-axis, starting from the positive Z-axis |
| NPLANE | A plane in which a flat blank to be generated, in reference to the coordinate system defined (CID): EQ.0 or 1: XY-plane (default) EQ.2: YZ-plane EQ.3: XZ-plane |
| CID | ID of a local coordinate system defined by *DEFINE_COORDINATE_SYSTEM. Default is 0 representing the global coordinate system. |
| PIDBK | Part ID of the blank, as defined by *PART. |
| NID | Starting node ID of the blank to be generated. |
| EID | Starting element ID of the blank to be generated. |
| XCENT | X-coordinate of the center of the blank. |
| YCENT | Y-coordinate of the center of the blank. |
| ZCENT | Z-coordinate of the center of the blank. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| SHIFT1 | First shift distance of the blank in the following axis in the coordinate system (CID) defined. NPLANE.EQ.1: X-axis NPLANE.EQ.2: Y-axis NPLANE.EQ.3: Z-axis |
| SHIFT2 | Second shift distance of the blank in the following axis in the coordinate system (CID) defined: NPLANE.EQ.1: Y axis NPLANE.EQ.2: Z-axis NPLANE.EQ.3: X-axis |

About the Keyword:

A flat and rectangular blank can be defined and meshed, which can be trimmed with IGES curves to a desired blank shape with complex periphery and inner cutouts. The mesh orientation is always parallel to the rectangular blank edge, and can be changed by defining the variable *ANGLE*. The blank outlines and inner holes can be defined using IGES curves and included in **DEFINE_CURVE_TRIM_2D* (not_3D). This feature is very useful for interactive input deck set up of metal forming simulation.

Example:

A complete keyword example of generating a flat blank with PID 1 is provided below. Referring to [Figure 15-40](#), the rectangular blank mesh is generated in the global XY-plane with its center at the global origin and a size of 1100.0×1050.0 mm. The square element edge length is 12 mm. The node and element ID numbers start at 8000 and 9000, respectively. An inner cut-out curve is provided by the IGES file *innerholes.iges*, and the blank outer line is defined with the IGES file *outerlines.iges*. Both files are included in the keyword **DEFINE_CURVE_TRIM_2D*. A seed point is defined indicating the portion that remains after trimming.

The blank and mesh orientation can be rotated about a particular axis. Following the right-hand rule, the blank in this case is rotated about Z-axis for a positive 30° ($ANGLE=30$) starting from the positive X-axis, as shown in [Figure 15-41](#).

Revision information:

This feature is available in LS-DYNA starting in Revision 59165. This keyword name was changed from `*CONTROL_FORMING_BLANKMESH` to `*DEFINE_FORMING_BLANKMESH` in Revision 69074. The variable `NPLANE` is available in Revision 69128. Some important updates are available in Revision 123603.

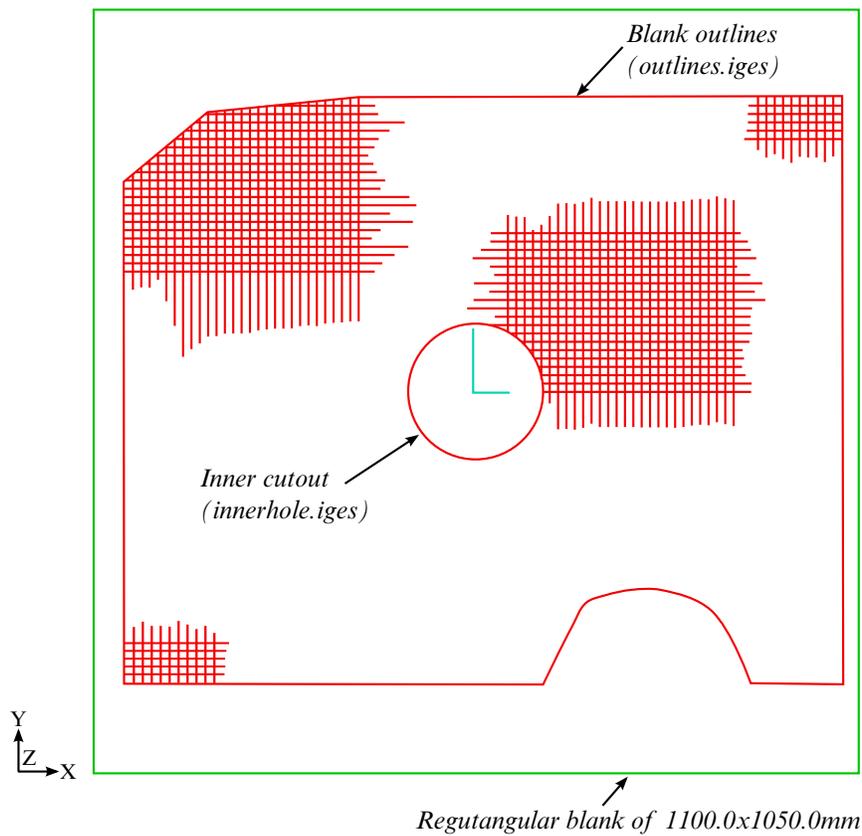

Figure 15-40. A rectangular blank mesh is generated and trimmed into a developed blank shape, with an inner cutout defined by innerhole.iges and outline defined by outlines.iges.

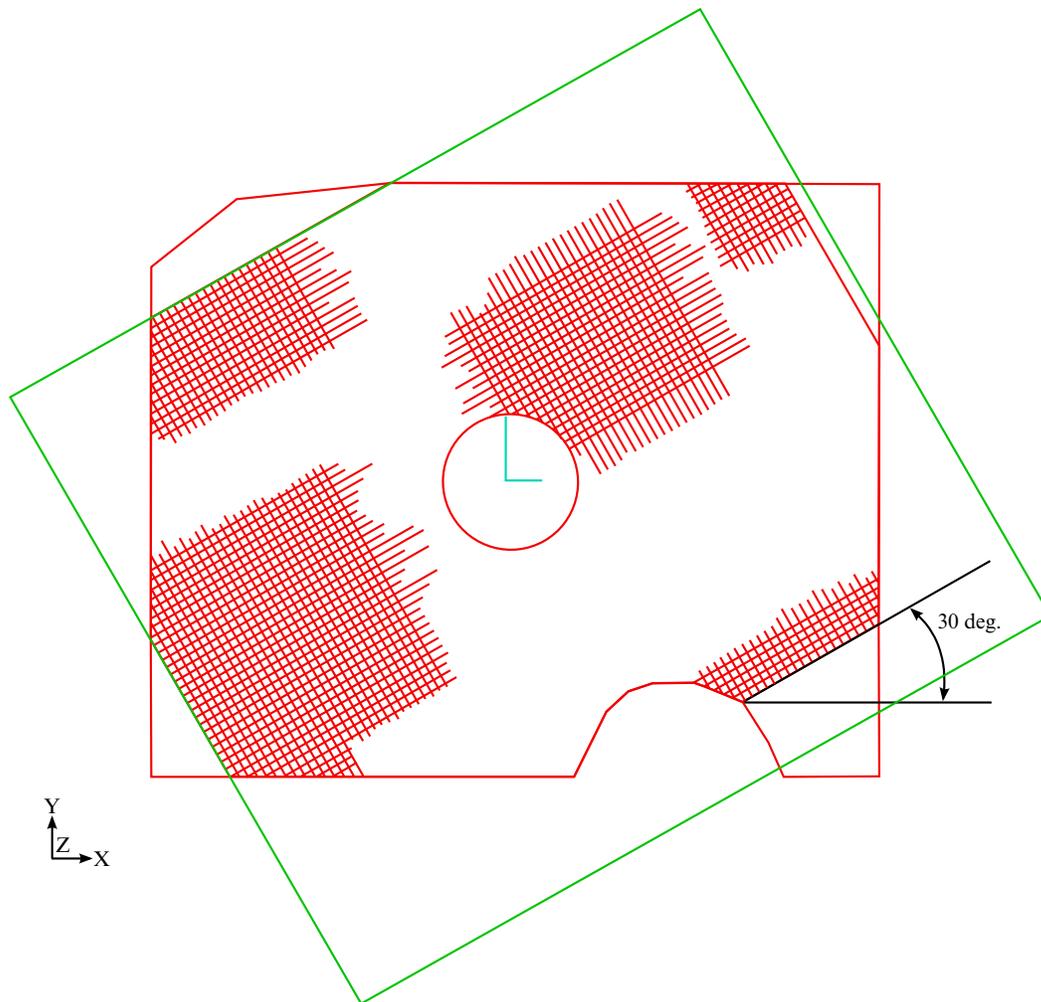

Figure 15-41. A rectangular blank mesh is generated in an angle (ANGLEX = 30) and trimmed into a developed blank shape, with an inner cutout defined by innerhole.iges and outline defined by outlines.iges. Note the blank mesh orientation is always parallel to the rectangular blank boundary.

***DEFINE_FORMING_CLAMP**

Purpose: This keyword acts as a macro that replaces the combination of cards required to model a clamping process. A related keyword is *DEFINE_FORMING_CONTACT.

Define Clamp Card. Define one card for each clamp set. Include as many cards in the following format as desired. This input ends at the next keyword ("**") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|-----|-----|-----|---|---|
| Variable | CLP1 | CLP2 | VID | GAP | AT | DT | | |
| Type | I | I | I | F | F | F | | |
| Default | none | none | none | 0.0 | 0.0 | 0.0 | | |

VARIABLE**DESCRIPTION**

| | |
|------|--|
| CLP1 | Part ID of a moving rigid body clamp, defined by *PART and *MAT_020 (*MAT_RIGID). |
| CLP2 | Part ID of a fixed rigid body clamp, defined by *PART and *MAT_020. This is sometimes called "net pad". |
| VID | Define CLP1 moving direction: GT.0: Vector ID from *DEFINE_VECTOR, specifying the moving direction of CLP1 LT.0: Absolute value is a node ID, whose normal vector will be used to define the moving direction of CLP1. |
| GAP | Final desired distance between CLP1 and CLP2 at the end of clamping. |
| AT | Begin time for CLP1's move. |
| DT | Duration of CLP1's move. |

About the keyword:

One typical application of this keyword is to estimate springback during the clamping of a formed panel on a checking fixture. Net pads (lower fixed regular or square pads) of a few millimeters thick are placed according to GD&T (*Geometry Dimensioning and*

Tolerancing) requirements on a support platform, typically taking shape of the nominal product. Each net pad (CLP2, see [Figure 15-42](#)) has a corresponding moving clamp (CLP1).

The movable clamp (CLP1) is initially open so that the formed panel can be loaded onto the net pads. Four-way and two-way position gaging pins are used to initially locate and load the panel in the fixture before CLP1 is moved to close with the net pad (CLP2). A white light scan is then performed on the panel, and scan data is processed to ascertain the degree of panel conformance to the required nominal shape. Even with the clamps fully closed, some severely distorted panels will significantly deviate from the nominal shape when the residual stresses from the forming process are too great.

Although, unrelated to this keyword another common method to determine the panel springback amount is the *free state* check which involves a white light scan on the panel secured on a platform but with no additional forces (clamps – CLP1s) applied to deform the panel (to the net pads CLP2s, for example). LS-DYNA can model both methods and job setups can be easily done by selecting *Implicit Static Flanging* process in LS-PrePost 4.2's *Metal Forming Application* → *eZ-Setup*. Furthermore, once springback has been determined, die compensation (*INTERFACE_COMPENSATION_3D) can then be performed to minimize or eliminate the springback; the resulting compensated die shapes can be surfaced, re-machined to produce panels that are within dimensional tolerance.

Since the clamp is, typically, modelled with a much coarser mesh than that on a blank, *CONTACT_FORMING_SURFACE_TO_SURFACE should be used. Rotating-type of clamps are currently not supported.

Application example:

A partial keyword example of using the feature is listed below. Referring to [Figure 15-42](#), the drawn and trimmed blank is positioned between the clamps CLP1 and CLP2. The implicit termination “time” is set at 1.0, with a stepping size of 0.25, for a total of four steps – two steps each for the two CLP1. With the original blank thickness of 1.0 mm, the CLP1s are set to close with the lower CLP2s at “time” of 1.0, leaving a total GAP of 1.02 mm. Note the VIDs are defined as “-46980”, indicating that the moving clamps (CLP1) will move in the normal direction defined by Node #46980. The contact definition between the panel and the clamps are defined using *DEFINE_FORMING_CONTACT.

```

Note with this keyword, the formed panel needs to be pre-positioned properly with respect to the clamps by users, and auto-position (*CONTROL_FORMING_AUTOPOSITION) cannot be used. Furthermore, prescribed motions and clamp motion curves do not need to be defined for the clamps.

Revision information:

This feature is available starting in double precision LS-DYNA Revision 99007 for implicit static only.

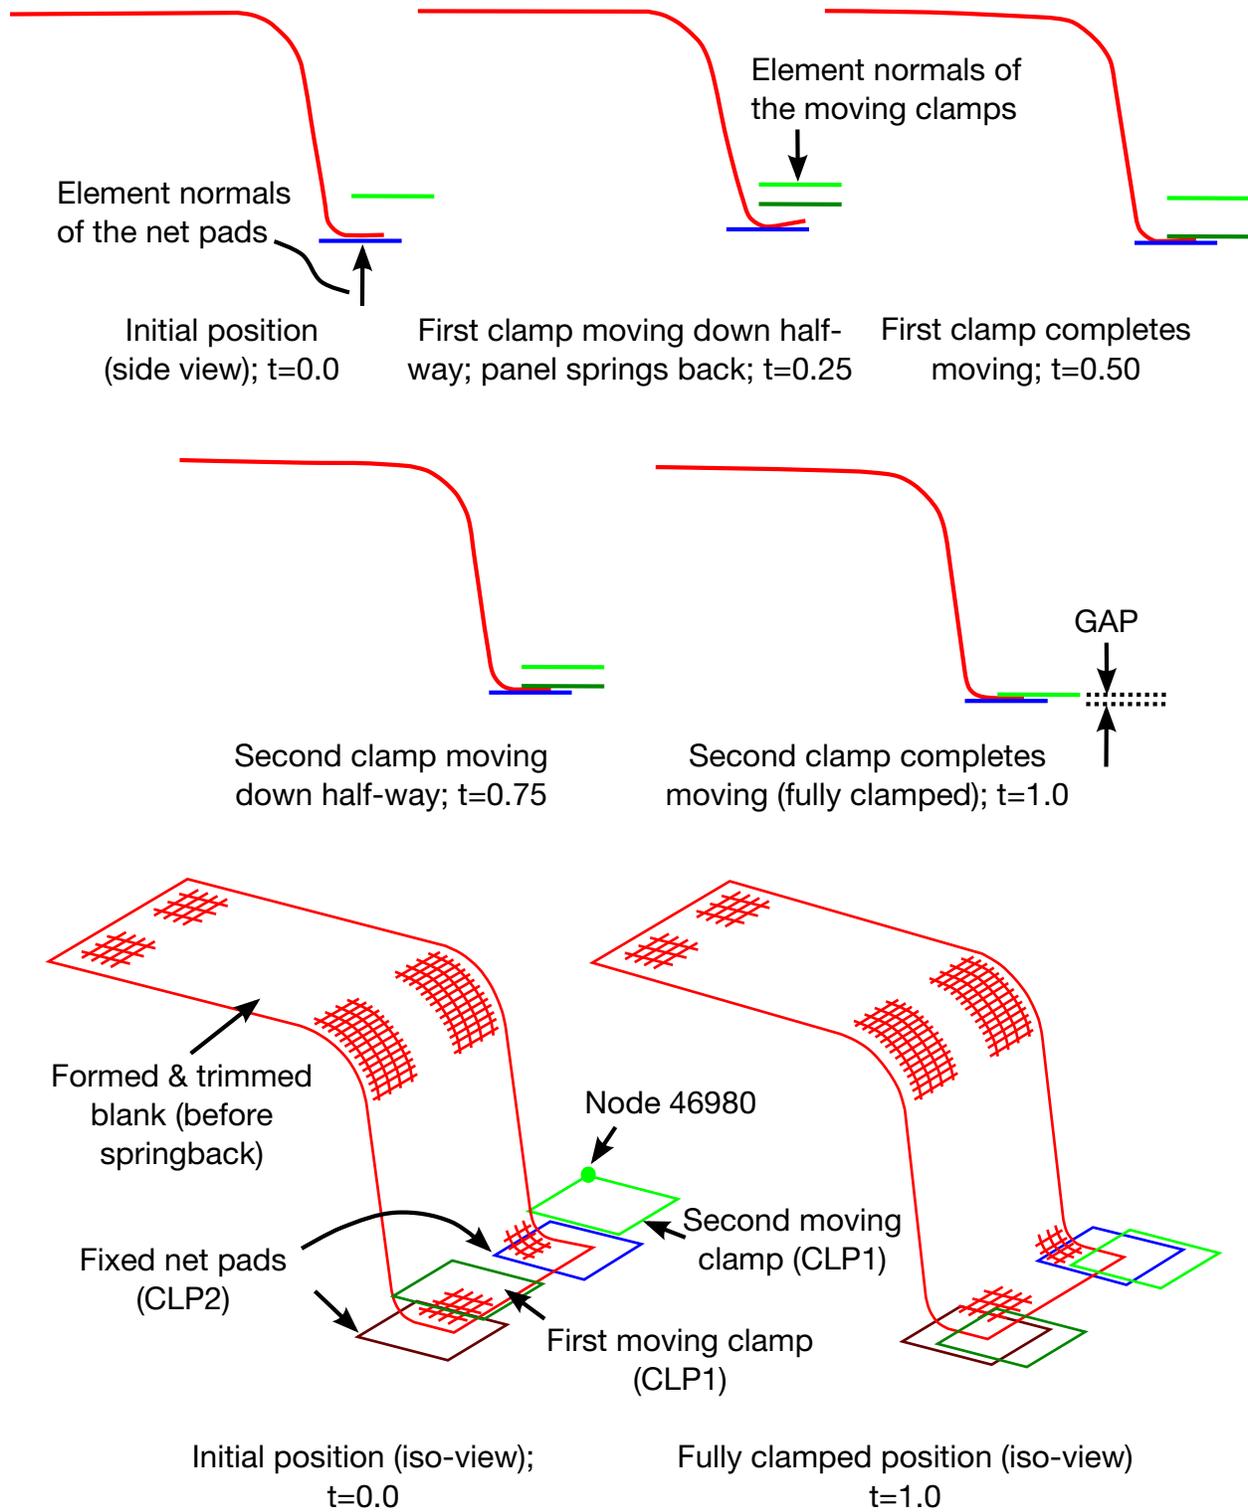

Figure 15-42. Variable definitions and an example of using the negative VID.

***DEFINE_FORMING_CONTACT**

Purpose: This keyword works as a macro for the FORMING_(ONE_WAY)_SURFACE_TO_SURFACE keyword. It adds one contact definition to the model per data card. Each data card consists of a reduced set of fields compared with the full *CONTACT keyword. The omitted fields take their default values. A related keyword is *DEFINE_FORMING_CLAMP.

Define Contact Card. Define one card for each contact interface. Define as many cards in the following format as desired. The input ends at the next keyword (“*”) card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|--------|---|---|---|---|
| Variable | IPS | IPM | FS | ONEWAY | | | | |
| Type | I | I | F | I | | | | |
| Default | none | none | none | 0 | | | | |

| VARIABLE | DESCRIPTION |
|----------|--|
| IPS | Part ID of a slave sliding member, typically a deformable sheet metal blank. |
| IPM | Part ID of a master sliding member, typically a tool or die defined as a rigid body. |

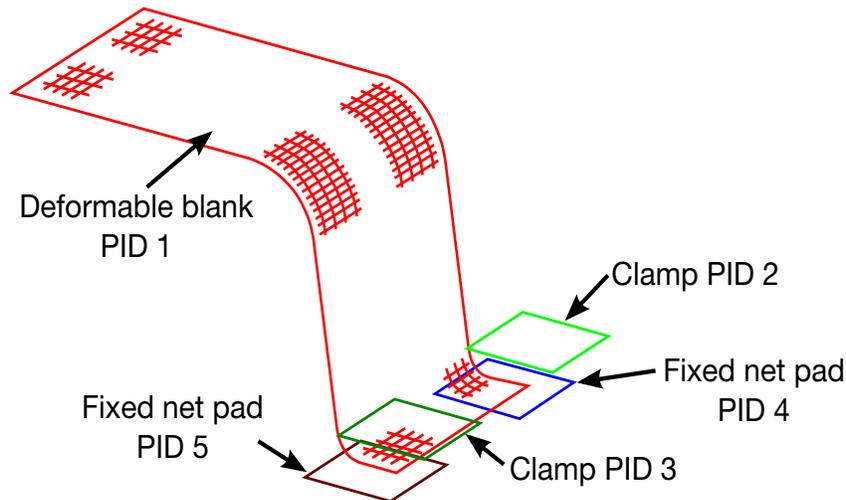

Figure 15-43. Define contact interfaces.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| FS | Coulomb friction coefficient. |
| ONEWAY | Define FORMING contact type: EQ.0: The contact is FORMING_ONE_WAY_SURFACE_TO_SURFACE. EQ.1: The contact is FORMING_SURFACE_TO_SURFACE. |

Application example:

A partial keyword example that defines contact between a deformable part and two pairs of clamps is given below. In [Figure 15-43](#), a blank (PID 1) is defined to have FORMING_SURFACE_TO_SURFACE contact with rigid body clamps (PIDs 2, 3, 4, and 5) with coefficient of frictions for each interface as 0.125, 0.100, 0.125, and 0.100, respectively. Only a total of four lines are needed to define four contact interfaces, as opposed to at least three cards for each interface using the contact keywords.

```

$---+---1---+---2---+---3---+---4---+---5---+---6---+---7---+---8
*DEFINE_FORMING_CONTACT
$      IPS      IPM      FS      ONEWAY
      1         2      0.125      1
      1         3      0.100      1
      1         4      0.125      1
      1         5      0.100      1

```

Revision information:

This feature is available starting in LS-DYNA Revision 98988.

***DEFINE_FRICTION**

Purpose: Define friction coefficients between parts for use with the contact options:

SINGLE_SURFACE

AIRBAG_SINGLE_SURFACE

AUTOMATIC_GENERAL

AUTOMATIC_SINGLE_SURFACE

AUTOMATIC_SINGLE_SURFACE_MORTAR

AUTOMATIC_NODES_TO_SURFACE

AUTOMATIC_SURFACE_TO_SURFACE

AUTOMATIC_SURFACE_TO_SURFACE_MORTAR

AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE

ERODING_SINGLE_SURFACE

The input ends at the next keyword ("*"). Default friction values are used for any part ID pair that is not defined.

The coefficient tables specified by the following cards are activated when **FS** (see second card of ***CONTACT**) is set to -2.0. This feature overrides the coefficients defined in ***PART_CONTACT** (which are turned on only when FS is set to -1.0).

When only *one* friction table is defined, it is used for *all* contacts having FS set to -2.0. Otherwise, for each contact with FS equal to -2.0, the keyword reader assigns a table to each ***CONTACT** by matching the value of **FD** from ***CONTACT** with an ID from Card 1 below. Failure to match FD to an ID causes error termination.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|---|---|---|
| Variable | ID | FS_D | FD_D | DC_D | VC_D | | | |
| Type | I | F | F | F | F | | | |
| Default | none | 0.0 | 0.0 | 0.0 | 0.0 | | | |

Friction *ij* card. Sets the friction coefficients between parts *i* and *j*. Add as many of these cards to the deck as necessary. The next keyword ("*") card terminates the friction definition.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------------------------|-------------------------|-------------------------|-------------------------|-------------------------|-------------------------|---------------------------|---------------------------|
| Variable | PID _{<i>i</i>} | PID _{<i>j</i>} | FS _{<i>ij</i>} | FD _{<i>ij</i>} | DC _{<i>ij</i>} | VC _{<i>ij</i>} | PTYPE _{<i>i</i>} | PTYPE _{<i>j</i>} |
| Type | I | I | F | F | F | F | A | A |
| Default | | | 0.0 | 0.0 | 0.0 | 0.0 | | |

VARIABLE**DESCRIPTION**

| | |
|------|---|
| ID | Identification number. Only one table is allowed. |
| FS_D | <p>Default value of the static coefficient of friction. The frictional coefficient is assumed to depend on the relative velocity v_{rel} of the surfaces in contact,</p> $\mu_c = FD + (FS - FD)e^{-DC v_{rel} }$ <p>Default values are used when part pair are undefined. For mortar contact $\mu_c = FS$, that is, dynamic effects are ignored.</p> |
| FD_D | <p>Default value of the dynamic coefficient of friction. The frictional coefficient is assumed to depend on the relative velocity v_{rel} of the surfaces in contact,</p> $\mu_c = FD + (FS - FD)e^{-DC v_{rel} }$ <p>Default values are used when part pair are undefined. For mortar contact $\mu_c = FS$, that is, dynamic effects are ignored.</p> |
| DC_D | <p>Default value of the exponential decay coefficient. The frictional coefficient is assumed to be depend on the relative velocity v_{rel} of the surfaces in contact,</p> $\mu_c = FD + (FS - FD)e^{-DC v_{rel} }$ <p>Default values are used when part pair are undefined. For mortar contact $\mu_c = FS$, that is, dynamic effects are ignored.</p> |

| VARIABLE | DESCRIPTION |
|------------------------------------|--|
| VC_D | <p>Default value of the coefficient for viscous friction. This is necessary to limit the friction force to a maximum. A limiting force is computed</p> $F_{\text{lim}} = VC \times A_{\text{cont}}$ <p>where A_{cont} is the area of the segment contacted by the node in contact. The suggested value for VC is to use the yield stress in shear $VC = \sigma_o / \sqrt{3}$ where σ_o is the yield stress of the contacted material. Default values are used when part pair are undefined.</p> |
| PID <i>i</i> | Part, or part set, ID <i>i</i> . |
| PID <i>j</i> | Part, or part set, ID <i>j</i> . |
| FS <i>ij</i> | Static coefficient of friction between parts <i>i</i> and <i>j</i> . |
| FD <i>ij</i> | Dynamic coefficient of friction between parts <i>i</i> and <i>j</i> . |
| DC <i>ij</i> | Exponential decay coefficient between parts <i>i</i> and <i>j</i> . |
| VC <i>ij</i> | Viscous friction between parts <i>i</i> and <i>j</i> . |
| PTYPE <i>i</i> , PTYPE <i>j</i> | EQ. "PSET": when PTYPE <i>i</i> or PTYPE <i>j</i> refers to a *SET_PART. |

***DEFINE_FRICTION_ORIENTATION**

Purpose: This keyword allows for definition of different coefficients of friction (COF) in specific directions, specified using a vector and angles in degree. In addition, COF can be scaled according to the amount of pressure generated in the contact interface. This keyword works in SMP only with *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE, including SMOOTH option. In MPP environment it works with *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE_ORTHO_FRICTION, including SMOOTH option. See [Revision information](#) for details.

This feature is developed jointly with the Ford Motor Company.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-------|-----|-----|-----|---|---|
| Variable | PID | LCID | LCIDP | V1 | V2 | V3 | | |
| Type | I | I | I | F | F | F | | |
| Default | none | 0 | 0 | 0.0 | 0.0 | 0.0 | | |

VARIABLE**DESCRIPTION**

| | |
|-------|--|
| PID | Part ID to which directional and pressure-sensitive COF is to be applied. See *PART. |
| LCID | ID of the load curve defining COF vs. orientation in degree. |
| LCIDP | ID of the load curve defining COF scale factor vs. pressure. |
| V1 | Vector components of vector V defining zero-degree (rolling) direction. |
| V2 | Vector components of vector V defining zero-degree (rolling) direction. |
| V3 | Vector components of vector V defining zero-degree (rolling) direction. |

The assumption:

Load curves LCID and LCIDP are not extrapolated beyond what are defined. It is recommended that the definition is specified for the complete range of angle and

combination with *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE_ORTHO_FRICTION for MPP application. In this combination, the variables LCID and LCIDP are overridden by friction factor input in ORTHO_FRICTION, while the vector [V1, V2, V3] defines the first orthogonal direction. It furthermore allows the convenience of defining SSID and MSID in *CONTACT as part set IDs (when SSTYP/MSTYP = 2), in which case the segments sets necessary for ORTHO_FRICTION are generated automatically with orientation according to the vectors defined by [V1, V2, V3]. A detailed keyword example is shown in [Figure 15-50](#).

Revision information:

This feature is available in LS-DYNA Revision 60275 and later releases for SMP, where it only supports *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE. It works in MPP environment with *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE_ORTHO_FRICTION starting from Rev 73226. In addition, the SMOOTH contact option is available starting from Revision 69631.

Use this keyword/vector to define rolling direction

Use *Set_part_list

FS ignored if ORTHO_FRICTION is present

FS1_S, LC1_S ignored if LCFS, LCPS are defined:
 LCFS: COF vs. Angle;
 LCPS: COF scale factor vs. Pressure.

FS1_M, LC1_M ignored if LCFM, LCPM are defined

1st orthogonal direction

1st Orthogonal direction follows slave segment orientation, as defined by 'a1' in *SET_SEGMENT; Ignored when defined with *DEFINE_FRICTION_ORIENTATION.

1st Orthogonal direction follows slave segment orientation, as defined by 'a1' in *SET_SEGMENT; Ignored when defined with *DEFINE_FRICTION_ORIENTATION.

Figure [15-50]. Use of this keyword with _ORTHO_FRICTION for MPP.

***DEFINE_FUNCTION**

Purpose: Define a function that can be referenced by a limited number of keyword options. The function arguments are different for each keyword that references *DEFINE_FUNCTION. Unless stated otherwise, all the listed argument(s) in their correct order must be included in the argument list. Some usages of *DEFINE_FUNCTION allow random ordering of arguments and argument dropouts. See the individual keywords for the correct format. Some examples are shown below.

NOTE: Unless the type of the function is explicitly given (as in example 2 below), the function will return an integer value if the name of the function starts with a letter in the range of i-n. Otherwise it will return a real value. For example, if a function is defined as "ifunc(x) = sqrt(x)", then ifunc(2.0) will return 1, not 1.414.

The TITLE option is not allowed with *DEFINE_FUNCTION.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|---------|---|---|---|---|---|---|
| Variable | FID | HEADING | | | | | | |
| Type | I | A70 | | | | | | |

Function Cards. Insert as many cards as needed. These cards are combined to form a single line of input. The next keyword ("*") card terminates this input.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|---|---|---|---|---|---|---|
| Variable | FUNCTION | | | | | | | |
| Type | A80 | | | | | | | |

VARIABLE**DESCRIPTION**

FID

Function ID. Functions, tables (see *DEFINE_TABLE), and load curves may not share common ID's. A unique number has to be defined.

HEADING

An optional descriptive heading.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| FUNCTION | Arithmetic expression involving a combination of independent variables and other functions, i.e., "f(a,b,c)=a*2+b*c+sqrt(a*c)" where a, b, and c are the independent variables. The function name, "f(a,b,c)", must be unique since other functions can then use and reference this function. For example, "g(a,b,c,d)=f(a,b,c)**2+d". In this example, two *DEFINE_FUNCTION definitions are needed to define functions f and g. |

Remarks:

- 1. Reserved names for variables and constants.** Certain useful constants are intrinsic and available through reserved names. For example, PI is the proportionality constant relating the circumference of a circle to its diameter, while DTOR and RTOD are respectively used to convert from degrees to radians, and vice versa. As well, TIME stores the current simulation time. These are just a few of the reserved variable names.
- 2. Trigonometric and other intrinsic functions.** Most trigonometric and other mathematical functions available in the Fortran and C programming languages are valid in *DEFINE_FUNCTION, for example, SIN, COS, ABS, and MAX. Please see a more complete list under "Intrinsic Functions" in *DEFINE_CURVE_FUNCTION.
- 3. Default is Radians.** Unless otherwise noted units of radians are always used for the arguments and output of functions involving angular measures.

The following examples serve only as an illustration of syntax.

Unlike *DEFINE_CURVE and *DEFINE_CURVE_FUNCTION, *DEFINE_FUNCTION is always active in dynamic relaxation phase.

Example 1:

Prescribe sinusoidal *x*-velocity and *z*-velocity for some nodes.

```

*BOUNDARY_PRESCRIBED_MOTION_SET
$#   nsid      dof      vad      lcid      sf
      1         1         0         1
      1         3         0         2
*DEFINE_FUNCTION
1,x-velo
x(t)=1000*sin(100*t)
*DEFINE_FUNCTION
2,z-velo
a(t)=x(t)+200

```

Example 2:

Ramp up a hydrostatic pressure on a submerged surface.

```
*comment
units: mks

Apply a hydrostatic pressure ramped up over a finite time = trise.

pressure on segment = rho * grav * depth of water
where depth of water is refy - y-coordinate of segment
and refy is the y-coordinate of the water surface

*DEFINE_FUNCTION
10
float hpres(float t, float x, float y, float z, float x0, float y0,
            float z0)
{
    float fac, trise, refy, rho, grav;
    trise = 0.1; refy = 0.5; rho = 1000.; grav = 9.81;
    fac = 1.0;
    if(t<=trise) fac = t/trise;
    return fac*rho*grav*(refy-y);
}
*LOAD_SEGMENT_SET
1,10
```

Example 2 illustrates that a programming language resembling C can be used in defining a function. Before a variable or function is used, its type must be declared; that is the purpose of "float" (i.e., a real variable rather than integer type) appearing before those entities. The braces indicate the beginning and end of the function being programmed. Semicolons must appear after each statement but several statements may appear on a single line. Please refer to a C programming guide for more detailed information.

*DEFINE

*DEFINE_FUNCTION_TABULATED

*DEFINE_FUNCTION_TABULATED

Purpose: Define a function of one variable using two columns of input data (in the manner of *DEFINE_CURVE) that can be referenced by a limited number of keyword options or by other functions defined via *DEFINE_FUNCTION. This command must appear in the keyword deck before the function it defines is used.

The TITLE option is not allowed with *DEFINE_FUNCTION_TABULATED.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | |
|----------|-----|---------|---|---|---|---|---|---|--|
| Variable | FID | HEADING | | | | | | | |
| Type | I | A70 | | | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|---|---|---|---|---|---|---|
| Variable | FUNCTION | | | | | | | |
| Type | A80 | | | | | | | |

Point Cards. Put one pair of points per card (2E20.0). Add as many cards as necessary. Input is terminated when a keyword ("*") card is found.

| Cards 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|---|-----|---|---|---|---|---|
| Variable | A1 | | 01 | | | | | |
| Type | F | | F | | | | | |
| Default | 0.0 | | 0.0 | | | | | |

VARIABLE

DESCRIPTION

FID

Function ID. Functions, tables (see *DEFINE_TABLE), and load curves may not share common ID's. A unique number has to be defined.

HEADING

An optional descriptive heading.

| VARIABLE | DESCRIPTION |
|-----------------|-----------------------------|
| FUNCTION | Function name. |
| A1, A2, ... | Abscissa values. |
| O1, O2, ... | Ordinate (function) values. |

Example:

```
*BOUNDARY_PRESCRIBED_MOTION_SET
$ function 300 prescribes z-acceleration of node set 1000
1000,3,1,300
*DEFINE_FUNCTION_TABULATED
201
tabfunc
0., 200
0.03, 2000.
1.0, 2000.
*DEFINE_FUNCTION
300
a(t)=tabfunc(t)*t
$ for t < 0.03, function 300 is equivalent to a(t)=(200. + 60000.*t)*t
$ for t >= 0.03, function 300 is equivalent to a(t)=(2000.)*t
```

***DEFINE_GROUND_MOTION**

Purpose: Define an earthquake ground motion history using ground motion records provided as load curves, for use in conjunction with *LOAD_SEISMIC_SSI for dynamic earthquake analysis including nonlinear soil-structure interaction.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|-------|---|---|---|---|---|
| Variable | GMID | ALCID | VLCID | | | | | |
| Type | I | I | I | | | | | |
| Default | none | none | 0 | | | | | |

VARIABLE**DESCRIPTION**

| | |
|-------|--|
| GMID | Ground motion ID. A unique number has to be defined. |
| ALCID | Load curve ID of ground acceleration history. |
| VLCID | Load curve ID of ground velocity history. |

Remarks:

1. Earthquake ground motion data is typically available either only as ground accelerations, or as a triple of ground accelerations, velocities and displacements. Usually, the velocities and the displacements are computed from the accelerations using specialized filtering and baseline correction techniques, e.g. see peer.berkeley.edu/smcat/process.html. Either input is accepted, with each quantity specified as a load curve. Only the acceleration and the velocity is required in the latter case; LS-DYNA does not require the ground displacement.
2. If only the ground acceleration data is provided for a particular ground motion, LS-DYNA generates a corresponding load curve for the velocity by integrating the acceleration numerically. The generated load curves are printed out to the D3HSP file. It is up to the user to ensure that these generated load curves are satisfactory for the analysis.

***DEFINE_HAZ_PROPERTIES**

Purpose: To model the heat affect zone in a welded structure, the yield stress and failure strain are scaled in shell models as a function of their distance from spot welds and the nodes specified in *DEFINE_HAZ_TAILOR_WELDED_BLANK.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|-----|-----|---------|---|---|---|---|
| Variable | ID_HAZ | IOP | PID | PID_TYP | | | | |
| Type | I | I | I | I | | | | |
| Default | 0 | 0 | 0 | 0 | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-----|-----|-----|-----|
| Variable | ISS | IFS | ISB | IFB | ISC | IFC | ISW | IFW |
| Type | I | I | I | I | I | I | I | I |
| Default | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

VARIABLE**DESCRIPTION**

| | |
|---------|--|
| ID_HAZ | Property set ID. A unique ID number must be used. |
| IOP | Activate scaling flag: EQ.0: Scaling not activated. EQ.1: Scaling activated. |
| PID | Part or part set ID. |
| PID_TYP | PID type. EQ.0: part ID EQ.1: part set ID |
| ISS | Curve ID for scaling the yield stress based on the distance to the closest solid element spot weld. Use a negative ID for curves normalized by the spot weld diameter as described in Remark 2 . |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| IFS | Curve ID for scaling the failure strain based on the distance to the closest solid element spot weld. Use a negative ID for curves normalized by the spot weld diameter as described in Remark 2 . |
| ISB | Curve ID for scaling the yield stress based on the distance to the closest beam element spot weld. Use a negative ID for curves normalized by the spot weld diameter as described in Remark 2 . |
| IFB | Curve ID for scaling the failure strain based on the distance to the closest beam element spot weld. Use a negative ID for curves normalized by the spot weld diameter as described in Remark 2 . |
| ISC | Curve ID for scaling the yield stress based on the distance to the closest constrained spot weld. Use a negative ID for curves normalized by the spot weld diameter as described in Remark 2 . |
| IFC | Curve ID for scaling the failure strain based on the distance to the closest constrained spot weld. Use a negative ID for curves normalized by the spot weld diameter as described in Remark 2 . |
| ISW | Curve ID for scaling the yield stress based on the distance to the closest tailor welded blank node. Use a negative ID for curves normalized by the spot weld diameter as described in Remark 2 . |
| IFW | Curve ID for scaling the failure strain based on the distance to the tailor welded blank node. Use a negative ID for curves normalized by the spot weld diameter as described in Remark 2 . |

Remarks:

1. **Scaling.** The yield stress and failure strain are assumed to vary radially as a function of the distance of a point to its neighboring spot welds. Since larger spot welds may have a larger radius of influence, the smallest scale factor for the yield stress from all the neighboring spot welds is chosen to scale the yield stress at a particular point. The failure strain uses the scaling curve for the same weld.
2. **Weld Diameter Normalization.** Curve IDs may be input as negative values to indicate that they are normalized by the diameter of the spot weld to compensate for the effects of the spot weld size. When this option is used, the scale factor is calculated based on the distance divided by the spot weld diameter for the spot weld that is closest to the element.

3. **Distance Measurement.** The distance from a spot weld (or node for the blank) is measured along the surface of the parts in the part set. This prevents the heat softening effects of a weld from jumping across empty space.
4. **Material Restrictions.** The HAZ capability only works with parts with materials using the STOCHASTIC option. It may optionally be simultaneously used with *DEFINE_STOCHASTIC_VARIATION to also account for the spatial variations in the material properties. See *DEFINE_STOCHASTIC_VARIATION for more details.

*DEFINE

*DEFINE_HAZ_TAILOR_WELDED_BLANK

*DEFINE_HAZ_TAILOR_WELDED_BLANK

Purpose: Specify nodes of a line weld such as in a Tailor Welded Blank. The yield stress and failure strain of the shell elements in the heat affected zone (HAZ) of this weld are scaled according to *DEFINE_HAZ_PROPERTIES.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|------|---|---|---|---|---|---|
| Variable | IDTWB | IDNS | | | | | | |
| Type | I | I | | | | | | |
| Default | 0 | 0 | | | | | | |

VARIABLE

DESCRIPTION

IDTWB

Tailor Welded Blank ID

IDNS

Node Set ID defining the location of the line weld.

***DEFINE_HEX_SPOTWELD_ASSEMBLY_{OPTION}**

Purpose: Define a list of hexahedral elements that make up a single spot weld for computing the force and moment resultants that are written into the `swforc` output file. A maximum of 16 elements may be used to define an assembly representing a single spot weld. See [Figure 15-51](#). This table of element IDs is generated automatically when beam elements are converted to solid elements. See the input parameter `RPBHX` associated with the keyword `*CONTROL_SPOTWELD_BEAM`.

Available options for this command are:

<BLANK>

N

For the <BLANK> option, all solid elements specified on Card 2 make up the spot weld and no additional card is read. For the N option, N is an integer representing the total number of solid elements making up the spot weld. If N is greater than 8, the additional card beyond Card 2 is read. N may not exceed 16.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|---|---|---|---|---|---|
| Variable | ID_SW | | | | | | | |
| Type | I | | | | | | | |

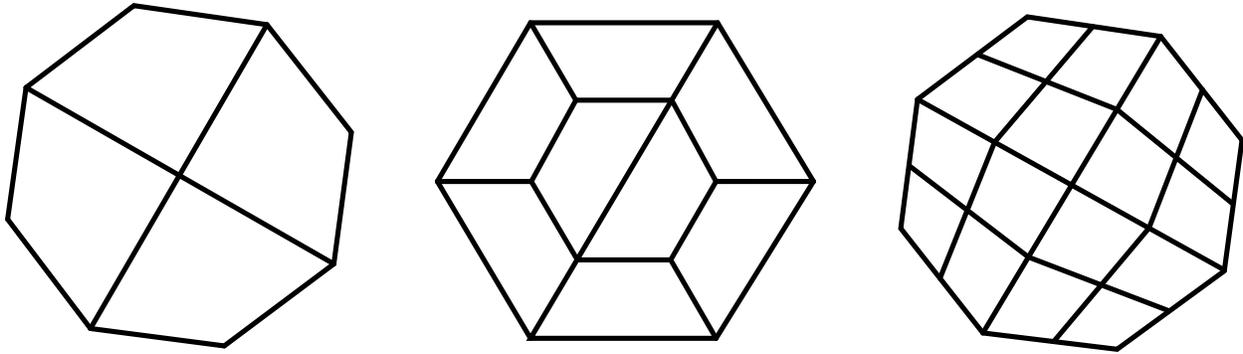

Figure 15-51. Illustration of four, eight, and sixteen element assemblies of solid hexahedron elements forming a single spot weld.

Additional card for $N > 8$.

| Optional | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|-------|-------|-------|-------|-------|-------|
| Variable | EID9 | EID10 | EID11 | EID12 | EID13 | EID14 | EID15 | EID16 |
| Type | I | I | I | I | I | I | I | I |
| Default | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

VARIABLE

DESCRIPTION

| | |
|---------|--|
| ID_SW | Spot weld ID. A unique ID number must be used. |
| EID n | Element ID n for up to 16 solid hexahedral elements. |

Remarks:

The elements comprising a spot weld assembly may share a part ID (PID) with elements in other spot weld assemblies defined using *DEFINE_HEX_SPOTWELD_ASSEMBLY but may not share a PID or even a material ID (MID) with elements that are not included in a *DEFINE_HEX_SPOTWELD_ASSEMBLY.

***DEFINE_LANCE_SEED_POINT_COORDINATES**

Purpose: Define seed points that determine the portion of a part(s) that is not removed (not scraps) during the trimming portion of lancing. This keyword is to be used in conjunction with *ELEMENT_LANCING. See *ELEMENT_LANCING.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-----|-----|-----|-----|-----|-----|---|
| Variable | NSEED | X1 | Y1 | Z1 | X2 | Y2 | Z2 | |
| Type | I | F | F | F | F | F | F | |
| Default | none | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | |

VARIABLE

DESCRIPTION

- NSEED Number of seed points. Maximum value of "2" is allowed.
- X1, Y1, Z1 Location coordinates of seed point #1.
- X2, Y2, Z2 Location coordinates of seed point #2.

Remarks:

- Trimming Restrictions.** This keyword will remove all scraps during or after lancing, depending on how the parameter AT is defined in *ELEMENT_LANCING. Lancing curves must form a closed loop, meaning the first and last point coordinates must be coincident. Scraps are the portions that are exclusive of the portions whose seed points are defined by this keyword.
- Example.** The following input defines two sets of seed point coordinates, where a double-attached part may be lanced and trimmed:

```
*DEFINE_LANCE_SEED_POINT_COORDINATES
$   NSEED      X1      Y1      Z1      X2      Y2      Z2
      2      -289.4    98.13  2354.679  -889.4    91.13   255.679
```

Revision Information

This feature is available starting with LS-DYNA Revision 107262.

***DEFINE_MATERIAL_HISTORIES**

Purpose: To control the content of the history variables in the d3plot database. This feature is supported for solid, beam and shell elements.

Define as many cards as needed to define the extra history variables. This input ends at the next keyword ****** card.

| Card 1 | 1 | 2 | 3 | 4 | 5 |
|----------|-------|-----|-----|-----|-----|
| Variable | LABEL | A1 | A2 | A3 | A4 |
| Type | A40 | F | F | F | F |
| Default | none | 0.0 | 0.0 | 0.0 | 0.0 |

VARIABLE**DESCRIPTION**

LABEL String identifying history variable type.

An Attributes, see discussion below.

Remarks:

Material models in LS-DYNA use history variables that are specific to the constitutive model being used. For most materials, 6 are reserved for the Cauchy stress components and 1 for the effective plastic strain, but many models have more than that. The history variables may include interesting physical quantities like material damage, material phase compositions, strain energy density and strain rate, but, in addition, they may also include nonphysical quantities like material direction cosines, scale factors and parameters that are used for the numerical algorithms but hard to interpret when post-processed.

By using NEIPS, NEIPB and NEIPH on ***DATABASE_EXTENT_BINARY**, these extra history variables can be exported to the d3plot database *in the order that they are stored*, and in LS-PrePost the variables may then be plotted (Hist button) or fringed (Misc menu). There are a few drawbacks with this approach. The user must, for instance, have knowledge of the storage location of a certain history variable for a given material model and element type. While this information can be retrieved either in the LS-DYNA manual, on LS-DYNA support sites or in LS-PrePost itself, it is not always convenient.

Furthermore, the same physical quantity may be stored in different locations for different materials and different element types, meaning that history variable #1 will correspond to different things in different parts which complicate post-processing of large models. The user may also be interested in a certain material specific quantity that is not necessarily stored as a history variable, this is not retrievable using this approach. Finally, if the history variable of interest happens to be stored in a bad location, i.e., among the last ones in a long list, it would be necessary to set NEIPS, NEIPB and/or NEIPH large enough to access this variable in LS-PrePost. This could result in unnecessarily large binary plot files.

The present keyword is an attempt to organize the extra history variables with respect to uniformity, a goal is to get an output that is reasonably small and easy to interpret. The input is very simple, use the keyword `*DEFINE_MATERIAL_HISTORIES` in the keyword input deck, followed by lines that specify the history variables of interest using predetermined labels and attributes. NEIPS, NEIPB and NEIPH on `*DATABASE_EXTENT_BINARY` will then be overridden by the number of history variables, i.e., number of lines, requested on this card. As an example

```
*DEFINE_MATERIAL_HISTORIES
  Instability
  Damage
```

would mean that two extra history variables are output to the d3plot database, so NEIPS, NEIPB and NEIPH will internally be set to 2 regardless of the user input. History variable #1 will correspond to an instability measure (between 0 and 1) and history variable #2 will correspond to a material damage (between 0 and 1), i.e., the history variables are output in the order they are listed. If there are several instances of this keyword in an input deck, then the order of the history variables will follow the order that the cards are read by the keyword reader.

In the d3hsp file the user may find the complete list by searching for the string “Material History List”. For a material that does not store or calculate an “instability” or “damage” history variable, the output will be zero and thus the output will not be cluttered by unwanted data. Note that this keyword does not necessarily require that the history variable be stored, as long as it can be calculated when LS-DYNA outputs a plot state. This opens for the possibility to request quantities that are not available by just using NEIPS, NEIPB and/or NEIPH on `*DATABASE_EXTENT_BINARY`.

For large models with many different parts and materials, the *Instability* or *Damage* variables should provide a comprehensive overview and understanding of the critical areas in terms of failure that otherwise may not be assessable.

The permitted LABELs (**case-sensitive**) are

| | |
|----------------------------|---|
| <i>Instability</i> | A number between 0 and 1 that indicates how close a element or integration point is to failure or to initiate damage, no attributes apply to this label. |
| <i>Damage</i> | A number between 0 and 1 indicating the damage level of the element or integration point, no attributes apply to this label. |
| <i>Plastic Strain Rate</i> | Effective plastic strain rate, calculated generically for “all” plastic materials from the evolution of effective plastic strain, no attributes apply to this label. |
| <i>Effective Stress</i> | Effective, or equivalent, stress. If not specifically stated in the material section for the material in question, this will be the von Mises stress. For selected anisotropic materials (such as the Barlat models) it is the stress value that is conjugate to effective plastic strain rate with respect to energy density rate. |
| <i>History</i> | Fetch a history variable at a known place for a given material type, element type and part set. The following attributes apply. A1 History variable location, mandatory. A2 Material type, default applies to all materials. A3 Element type, 0 for all element types, 1 for solids, 2 for shells and 3 for beams. A4 Part set, history will only be fetched from the parts in the given part set. The default is all parts in the model. |

Examples:

The History label is for users who know where history variables of interest are stored and want to use this to compress or simplify the output. An example is

```
*DEFINE_MATERIAL_HISTORIES
History,4,272,1,23
History,1,81
*SET_PART_LIST
23
2,3
```

which will make a list of two history variables in the output. History variable #1 will fetch the 4th history variable, but displayed only for the RHT concrete model (material 272), solid elements and in parts 2 and 3. History variable #2 will fetch the 1st history variable, display it only for the plasticity with damage model (material 81), but for any

element and part. Both of these requested variables happen to be the damage in the respective materials, so an alternative to do something similar would be to use

```
*DEFINE_MATERIAL_HISTORIES
Damage
```

for which the damage for all materials will be displayed in history variable #1.

The history variables that may be requested using this keyword are tabulated in the individual material model chapters, see Volume II of the Keyword Users' Manual. At the end of the remarks for a material model, a table such as the one below is present if there are retrievable history variables.

| <i>*DEFINE_MATERIAL_HISTORIES Properties</i> | | |
|--|-------------------|---|
| Label | Attributes | Description |
| Instability | - - - - | Failure indicator $\epsilon_{eff}^p / \epsilon_{fail}^p$, see FAIL |
| Plastic Strain Rate | - - - - | Effective plastic strain rate $\dot{\epsilon}_{eff}^p$ |

Whether mentioned in such table or not, *Plastic Strain Rate* is available for any material model that calculates plastic strain as the 7th standard history variable. *Label* in the table states what the string LABEL on *DEFINE_MATERIAL_HISTORIES must be, *a1* to *a4* will list attributes A1 to A4 if necessary, and *Description* will be a short description of what is output with this option, including possible restrictions. Further development of this keyword will mainly be driven by customer requests submitted to suggestions@lstc.com. Currently only solid, beam and shell elements are supported for the binary d3plot format, a goal is to include thick shells and support ascii/binout output in future versions of LS-DYNA.

Note:

The *Labels* are **case-sensitive**.

*DEFINE

*DEFINE_MULTI_DRAWBEADS_IGES

*DEFINE_MULTI_DRAWBEADS_IGES

Purpose: This keyword is developed to simplify the definition and creation of draw beads, which previously required the use of many keywords.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|---|---|---|---|---|---|---|
| Variable | FILENAME | | | | | | | |
| Type | A80 | | | | | | | |
| Default | none | | | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-----|-------|------|---|---|---|
| Variable | DBID | VID | PID | BLKID | NCUR | | | |
| Type | I | I | I | I | I | | | |
| Default | none | none | 1 | 1 | none | | | |

IGES Curve ID cards. For multiple draw bead curves include as many cards as necessary. Input is terminated at the next ("*") card.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|--------|---|---|---|---|---|---|
| Variable | CRVID | BFORCE | | | | | | |
| Type | I | F | | | | | | |
| Default | none | 0.0 | | | | | | |

VARIABLE

DESCRIPTION

DBID

Draw bead set ID, which may consist many draw bead segments.

VID

Vector ID, as defined by *DEFINE_VECTOR. This vector is used to project the supplied curves to the rigid tool, defined by PID.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| PID | Part ID of a rigid tool to which the curves are projected and attached. |
| BLKID | Part ID of the sheet blank with which created draw beads will contact. |
| NCUR | Number of draw bead curve segments (in the IGES file defined by FILENAME) to be defined. |
| CVRID | IGES curve ID for each segment. |
| BFORCE | Draw bead force for each segment. |

Remarks:

1. This keyword alone can be used to define draw bead forces for a stamping part. The following partial keyword example shows a draw bead set with ID 98, consists of three curves with ID, 12, 23, and 45, each with bead forces of 102.1, 203.3, 142.5 N/mm, respectively, is being created for a blank with part ID 1. The beads are projected along vector ID 99, and are attached to a rigid tool with part ID 3. The IGES file to define the draw bead curve is "drawbeads3.iges". Note rigid tool the draw beads are attached should be upper die in air draw, or lower cavity in toggle draw.

```
*DEFINE_MULTI_DRAWBEADS_IGES
drawbead3.iges
$   DBID      VID      PID      BLKID      NCUR
    98        99        3         1         3
$   CRVID     BFORCE
    12        102.1
    23        203.3
    45        142.5
*define_vector
99,0.0,0.0,0.0,0.0,0.0,1.0
```

Revision information:

This feature is available in LS-DYNA R5 Revision 62840 and later releases.

***DEFINE_NURBS_CURVE**

Purpose: Define a NURBS curve using a univariate knot vector, a control polygon, and optionally a set of control weights. The knot vector defines the necessary shape functions and parameterize the curve. There is no limit on the size of the input data. Hence, the total number of keyword cards depends on the parameters defined on the first card. The total number of cards is $1 + \text{ceil}[(N+P+1)/8] + N$, where N and P designate the number of control points forming the control polygon and the polynomial degree, respectively. An example clamped NURBS curve and its corresponding keyword deck is shown in [Figures 15-52](#) and [15-53](#), respectively.

While the keyword is meant to store NURBS curves in two or three spatial dimension, it is also employed to describe trimming curves defining trimmed NURBS elements/surfaces, see ***ELEMENT_SHELL_NURBS_PATCH** for further details. In the latter case, the control point coordinates are in fact parametric coordinates of the surface to be trimmed, i.e. $(x,y,z,w)=(r,s,0,w)$ and TYPE = 1 on Card 1.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|-----|---|---|
| Variable | ID | N | P | PERI | TYPE | WFL | | |
| Type | I | I | I | I | I | I | | |
| Default | none | none | none | 0 | 0 | 0 | | |

Knot Vector Cards. The knot vector of length $N+P+1$ is given below requiring $\text{ceil}[(N+P+1)/8]$ cards in total. The knot vector has to be normalized to the $[0,1]$ interval.

| Cards A | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | K1 | K2 | K3 | K4 | K5 | K6 | K7 | K8 |
| Type | F | F | F | F | F | F | F | F |
| Default | none |

Control point cards. The spatial coordinates of the control points and the control weights are listed on N cards. Control weight entries are disregarded unless WFL = 1 on Card 1.

| Cards B | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|---|---|---|---|
| Variable | X | Y | Z | W | | | | |
| Type | F | F | F | F | | | | |
| Default | none | none | none | none | | | | |

VARIABLE**DESCRIPTION**

| | |
|-------|---|
| ID | Curve ID. A unique number has to be chosen. |
| N | Number of control points. |
| P | Polynomial degree. |
| PERI | Flag for curve periodicity. EQ.0: Non-periodic. EQ.1: Periodic. |
| TYPE | Coordinate type. EQ.0: Spatial. EQ.1: Parametric. |
| WFL | Flag for user defined control weights. EQ.0: Control weights are assumed to be uniform and positive, i.e. the curve is a B-spline curve, and the fourth entries on cards B are disregarded. EQ.1: Control weights are defined on the fourth entry of cards B. |
| K_n | Values of the univariate knot vector defined in cards A with $n = 1, \dots, N+P+1$. |
| X_k | Spatial coordinates in the global X direction defined in cards B with $k = 1, \dots, N$. |

- Y_k Spatial coordinates in the global Y direction defined in cards B with $k = 1, \dots, N$.
- Z_k Spatial coordinates in the global Z direction defined in cards B with $k = 1, \dots, N$.
- W_k Control weights defined in cards B with $k = 1, \dots, N$.

```

Figure 15-53. Defining the quadratic NURBS curve using the *DEFINE_NURBS_CURVE keyword.

***DEFINE_PART_FROM_LAYER**

Purpose: This keyword creates new blank(s) from an existing sheet blank, often used to model composite layers. This keyword applies to shell elements only, and not applicable to adaptive remeshing.

Multiple layers can be defined. Input ends with the next “*”.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|---------|--------|------|-------|---|---|
| Variable | PID | LAYER | PIDSRCE | LAYOLD | MID | THICK | | |
| Type | I | I | I | I | I | F | | |
| Default | none | none | none | none | none | none | | |

VARIABLE**DESCRIPTION**

| | |
|---------|---|
| PID | The part ID to be created. |
| LAYER | The layer ID of the PID, see Figure 15-54 . |
| PIDSRCE | The part ID of the existing blank to be copied from. |
| LAYOLD | The layer ID of the existing blank. |
| MID | The material ID of the PID. |
| THICK | The thickness of the PID. |

Remarks:

1. This keyword can be used to create multiple composite sheet layers from an existing layer of sheet blank. Based on the layer ID convention as outlined in Figure 1, one can create many layers of composite blanks with this keyword.
2. This keyword allows user to skip the definition of *PART, and *SECTION_SHELL for the to-be created composite layer, whilst *MAT, and contact cards still need to be defined.
3. Contact between outer layer of composites and the tools can be modeled using *CONTACT_FORMING_ONE_WAY_SURFACE_TO_SURFACE, while *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_COMPOSITE, or *CON-

TACT_AUTOMATIC_SURFACE_TO_SURFACE can be used to model the interactions between two composite layers.

- The following keyword defines new sheet metal blanks with part IDs 5 and 6, from an existing sheet blank with PID 4, and positions PID 5 on top of PID4 and PID6 on top of PID5.

```
*DEFINE_PART_FROM_LAYER
$---+---1---+---2---+---3---+---4---+---5---+---6---+---7---+---8
$      PID      LAYER  PIDSRCE  LAYOLD      MID      THICK
          5          2          4          1          5          0.10
          6          3          4          1          5          0.10
$---+---1---+---2---+---3---+---4---+---5---+---6---+---7---+---8
```

- Starting in Dev Revision 124300, although invisible to the users, contact definitions will be automatically defined between all adjacent layers using *CONTACT_SURFACE_TO_SURFACE during the simulation.

Revision Information:

This feature is available starting from Dev Revision 117590. Automatic contact is available in Dev Revision 124300.

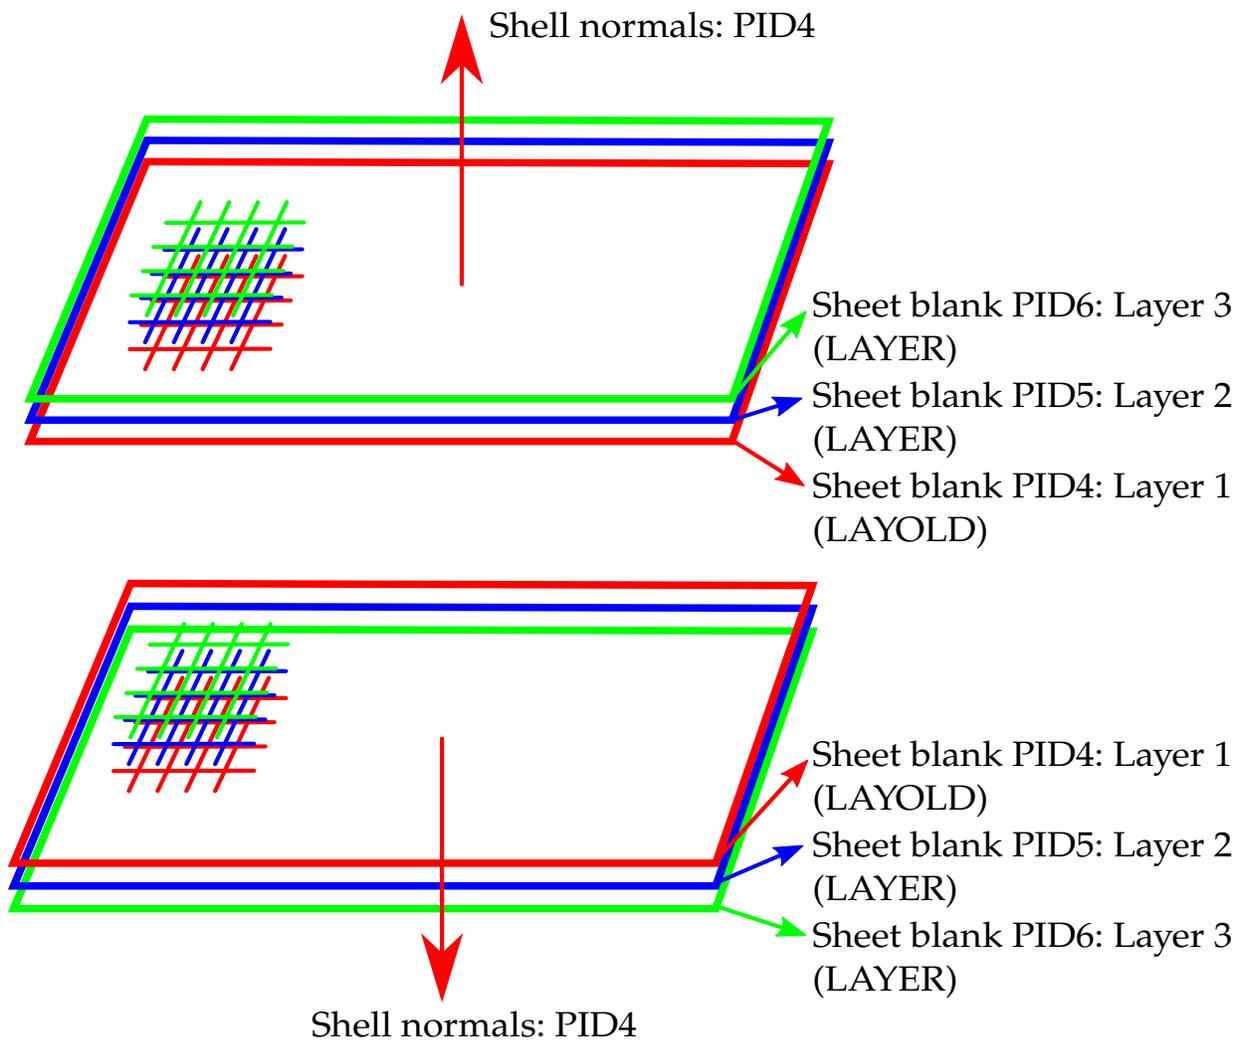

Figure 15-54. Defining the variables LAYER and LAYOLD.

*DEFINE

*DEFINE_PBLAST_AIRGEO

*DEFINE_PBLAST_AIRGEO

Purpose: To define a simple geometry for initial air domain.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|--------|--------|---|---|---|---|---|

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|----|----|----|----|---|---|
| Variable | XA | YA | ZA | XB | YB | ZB | | |
| Type | F | F | F | F | F | F | | |
| Default | 0. | 0. | 0. | 0. | 0. | 0. | | |

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|----|----|----|----|---|---|
| Variable | X0 | Y0 | Z0 | G1 | G2 | G3 | | |
| Type | F | F | F | F | F | F | | |
| Default | 0. | 0. | 0. | 0. | 0. | 0. | | |

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|----|----|----|----|---|---|
| Variable | XC | YC | ZC | G4 | G5 | G6 | | |
| Type | F | F | F | F | F | F | | |
| Default | 0. | 0. | 0. | 0. | 0. | 0. | | |

| VARIABLE | DESCRIPTION |
|------------------|---|
| GID | ID of a GEOMETRY defining initial air particle domain. |
| GTYPE1 GTYPE2 | Geometry type EQ.1: box EQ.2: sphere EQ.3: cylinder EQ.4: ellipsoid EQ.5: hemisphere (see Remark 1) |
| XA, YA, ZA | (XA, YA, ZA) defines a vector of the x -axis |
| XB, YB, ZB | (XB, YB, ZB) defines a vector of the y -axis |
| X0, Y0, Z0 | Center coordinates of air domain |
| G1 | Dimension value depending on GTYPE. GTYPE.EQ.1: length of x edge GTYPE.EQ.2: Radius of sphere GTYPE.EQ.3: Radius of cross section GTYPE.EQ.4: length of x -axes GTYPE.EQ.5: Radius of hemisphere |
| G2 | Dimension value depending on GTYPE. GTYPE.EQ.1: length of y edge GTYPE.EQ.3: length of cylinder GTYPE.EQ.4: length of y -axes |
| G3 | Dimension value depending on GTYPE. GTYPE.EQ.1: length of z edge GTYPE.EQ.4: length of z -axes |
| XC, YC, ZC | Center coordinates of domain excluded from the air domain |
| G4, G5, G6 | See definition of G1, G2, G3 |

Remarks:

1. If GTYPE1/GTYPE2 is 5, the hemisphere is defined in negative z direction defined by the cross product of the y and x axis.

***DEFINE_PBLAST_GEOMETRY**

Purpose: To define a simple geometry for high explosives domain.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-------|---|---|---|---|---|---|
| Variable | GID | GTYPE | | | | | | |
| Type | I | I | | | | | | |
| Default | 0 | none | | | | | | |

| Type | F | F | F | F | F | F | | |
| Default | 0. | 0. | 0. | 0. | 0. | 0. | | |

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|----|---|---|---|---|---|
| Variable | XC | YC | ZC | | | | | |
| Type | F | F | F | | | | | |
| Default | 0. | 0. | 0. | | | | | |

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|----|---|---|---|---|---|
| Variable | G1 | G2 | G3 | | | | | |
| Type | F | F | F | | | | | |
| Default | 0. | 0. | 0. | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| GID | ID of a GEOMETRY defining high explosive particle domain. |
| GTYPE | Geometry type EQ.1: box EQ.2: sphere EQ.3: cylinder EQ.4: ellipsoid EQ.5: hemisphere (see Remark 1) |
| XA, YA, ZA | (XA,YA,ZA) defines a vector of the x -axis |
| XB, YB, ZB | (XB,YB,ZB) defines a vector of the y -axis |
| XC | X-coordinate of charge center |
| YC | Y-coordinate of charge center |
| ZC | Z-coordinate of charge center |
| G1 | GTYPE.EQ.1: length of x edge GTYPE.EQ.2: Radius of sphere GTYPE.EQ.3: Radius of cross section GTYPE.EQ.4: length of x -axes GTYPE.EQ.5: Radius of hemisphere |
| G2 | GTYPE.EQ.1: length of y edge GTYPE.EQ.3: length of cylinder GTYPE.EQ.4: length of y -axes |
| G3 | GTYPE.EQ.1: length of z edge GTYPE.EQ.4: length of z -axes |

Remarks:

1. **Hemisphere.** If GTYPE is 5, the hemisphere is defined in negative z -direction defined by the cross product of the y - and x -axes.

***DEFINE_PLANE**

Purpose: Define a plane with three non-collinear points. The plane can be used to define a reflection boundary condition for problems like acoustics.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-----|-----|-----|-----|
| Variable | PID | X1 | Y1 | Z1 | X2 | Y2 | Z2 | CID |
| Type | I | F | F | F | F | F | F | I |
| Default | 0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0 |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|---|---|---|---|---|
| Variable | X3 | Y3 | Z3 | | | | | |
| Type | F | F | F | | | | | |
| Default | 0.0 | 0.0 | 0.0 | | | | | |

VARIABLE**DESCRIPTION**

| | |
|-----|--|
| PID | Plane ID. A unique number has to be defined. |
| X1 | X-coordinate of point 1. |
| Y1 | Y-coordinate of point 1. |
| Z1 | Z-coordinate of point 1. |
| X2 | X-coordinate of point 2. |
| Y2 | Y-coordinate of point 2. |
| Z2 | Z-coordinate of point 2. |
| CID | Coordinate system ID applied to the coordinates used to define the current plane. The coordinates X1, Y1, Z1, X2, Y2, Z2, X3, Y3 and Z3 are defined with respect to the coordinate system CID. |
| X3 | X-coordinate of point 3. |

| VARIABLE | DESCRIPTION |
|-----------------|--------------------------|
| Y3 | Y-coordinate of point 3. |
| Z3 | Z-coordinate of point 3. |

Remarks:

1. **Setup Suggestions.** The coordinates of the points must be separated by a reasonable distance and not collinear to avoid numerical inaccuracies.

***DEFINE_POROUS_OPTION**

Available options include:

ALE

LAGRANGIAN

Purpose: The *DEFINE_POROUS_ALE card defines the Ergun porous coefficients for ALE elements. It is to be used with *LOAD_BODY_POROUS. This card with the LAGRANGIAN option, *DEFINE_POROUS_LAGRANGIAN, defines the porous coefficients for Lagrangian elements and is to be used with *CONSTRAINED_LAGRANGE_IN_SOLID (slave parts with CTYPE = 11 or 12).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|-------|--------|--------|---------|---|---|
| Variable | EIDBEG | EIDEND | LOCAL | VECID1 | VECID2 | USERDEF | | |
| Type | I | I | I | I | I | I | | |
| Default | none | 0 | 0 | 0 | 0 | 0 | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-----|-----|---|---|
| Variable | Axx | Axy | Axz | Bxx | Bxy | Bxz | | |
| Type | F | F | F | F | F | F | | |
| Default | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | | |

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-----|-----|---|---|
| Variable | Ayx | Ayy | Ayz | Byx | Byy | Byz | | |
| Type | F | F | F | F | F | F | | |
| Default | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | | |

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-----|-----|---|---|
| Variable | Azx | Azy | Azz | Bzx | Bzy | Bzz | | |
| Type | F | F | F | F | F | F | | |
| Default | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | | |

VARIABLE**DESCRIPTION**

EIDBEG,
EIDEND

EIDBEG, EIDEND > 0: Range of thick porous element IDs. These are solids in 3D and shells in 2D.

EIDBEG, EIDEND < 0: Range of thin porous element IDs. These are shells in 3D and beams in 2D. The ALE option does *not* support thin porous elements.

EIDBEG > 0, EIDEND = 0: EIDBEG is a set of thick porous elements

EIDBEG > 0, EIDEND < 0: EIDBEG is a set of thin porous elements

LOCAL

Flag to activate an element coordinate system:

EQ.0: The forces are applied in the global directions.

EQ.1: The forces are applied in a local system attached to the element. The system is consistent with DIREC = 1 and CTYPE = 12 in *CONSTRAINED_LAGRANGE_IN_SOLID. For CTYPE = 11, LOCAL is always 1 and the x -axis is aligned with the element normal while the y -axis passes through the element center and the first node in the element connectivity (*ELEMENT_BEAM in 2D or *ELEMENT_SHELL in 3D)

| VARIABLE | DESCRIPTION |
|-------------------|---|
| VECID1, VECID2 | *DEFINE_VECTOR IDs to define a specific coordinate system. VECID1 and VECID2 give the x - and y -direction respectively. The z -vector is a cross product of VECID1 and VECID2. If this latter is not orthogonal to VECID1, its direction will be corrected with a cross-product of z - and x -vectors. The vectors are stored as isoparametric locations to update their directions if the element deforms or rotates. |
| USERDEF | Flag to compute A_{ij} and B_{ij} with a user defined routine in the file dyn21.F called lagpor_getab_userdef. The file is part of the general package usermat. |
| A_{ij} | Viscous matrix for the porous flow Ergun equation. (see Remark 1): |
| B_{ij} | Inertial matrix for the porous flow Ergun equation. (see Remark 1): |

Remarks:

1. **Ergun Equation.** The Ergun equation computing the pressure gradient along each direction $i = x, y, z$ can be written as follows:

$$\frac{dP}{dx_i} = \sum_{j=1}^3 [\mu A_{ij} V_j + \rho B_{ij} |V_j| V_j]$$

where,

- a) V_i is the relative velocity of the flow in the porous media
- b) A_{ij} are the viscous coefficients of the Ergun-type porous flow equation in the i^{th} direction.. This matrix is similar to the viscous coefficients used in *LOAD_BODY_POROUS.
- c) B_{ij} are the inertial coefficient of the Ergun-type porous flow equation in the i^{th} direction. This matrix is similar to the inertial coefficients used in *LOAD_BODY_POROUS.

If this keyword defines the porous properties of Lagrangian elements in *CONSTRAINED_LAGRANGE_IN_SOLID, the porous coupling forces are computed with the pressure gradient as defined above instead of the equations used for CTYPE = 11 and 12.

*DEFINE

*DEFINE_PRESSURE_TUBE

*DEFINE_PRESSURE_TUBE

Purpose: Define a gas filled tube for the simulation of interior pressure waves that result from changes in the tube cross section area over time. The tube is defined by tubular beam elements, and the initial gas volume is determined by beam cross section area and initial element lengths. Area changes are either given by beam contact penetration (only mortar contacts currently supported) or by deformation of automatically generated shell/solid elements. The pressure calculation is not coupled with the beam deformation and does not use any data from the material card. Pressure and tube area at the beam nodes are output through *DATABASE_PRTUBE.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|------|---|---|---|
| Variable | PID | WS | PR | MTD | TYPE | | | |
| Type | I | F | F | I | I | | | |
| Default | 0 | 0.0 | 0.0 | 0 | 0 | | | |

Optional card 1 (MTD = 0)

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|------|------|------|---|---|---|
| Variable | VISC | CFL | DAMP | BNDL | BNDR | | | |
| Type | F | F | F | F | F | | | |
| Default | 1.0 | 0.9 | 0.0 | 0.0 | 0.0 | | | |

Automatically Generated Shells Card. This card is read if and only if TYPE = 1.

| Card 3a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|-----|------|----------|---|---|---|
| Variable | NSHL | ELFORM | NIP | SHRF | BPID | | | |
| Type | F | F | F | F | I | | | |
| Default | 12.0 | 16.0 | 3.0 | 1.0 | optional | | | |

Automatically Generated Solids Card. This card is read if and only if TYPE = 2.

| Card 3b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|------|---|----------|---|---|---|
| Variable | NSLD | ELFORM | NTHK | | BPID | | | |
| Type | F | F | F | | I | | | |
| Default | 12.0 | 1.0 | 3.0 | | optional | | | |

VARIABLE**DESCRIPTION**

| | |
|-----|--|
| PID | <p>Part ID of tube. All connected beam elements in the part will model a tube. Only tubular beam elements are allowed, that is, ELFORM = 1, 4, 5, and 11 with CST = 1 on *SECTION_BEAM. Initial tube cross sectional area is calculated using the beam inner diameter TT1/TT2 fields in the *SECTION_BEAM keyword. If no inner diameter is given, the outer diameter TS1/TS2 fields in the *SECTION_BEAM keyword is used.</p> <p>The beam elements may not contain junctions. Two different parts on which *DEFINE_PRESSURE_TUBE is defined may not share nodes. For MPP all elements in the part will be on a single processor.</p> |
| WS | Speed of sound c_0 in the gas |
| PR | Initial gas pressure p_0 inside tube |
| MTD | <p>Solution method:</p> <p>EQ.0: Standard Galerkin FEM; see Remarks.</p> |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| TYPE | <p>Tube element type:</p> <p>EQ.0: the tube is entirely simulated with beam elements. Cross section area is given from contact penetration of the beam elements. The mechanical response in radial direction of the beam elements is governed by contact stiffness. Only mortar contacts are supported.</p> <p>EQ.1: the tube is simulated by automatic generation of shell elements, which are assigned the beam part ID and the beam material model. A new part ID is given to the beam elements, and those are no longer part of the mechanical solution. Contacts and other properties associated with the old beam part ID will now apply to the new shell part. Cross section area is given from the shell element nodes, and the mechanical response is governed entirely by the shells. Supports all contact definitions. Boundary conditions defined by *BOUNDARY_{SPC, PRESCRIBED_MOTION} are moved to the new shell tube.</p> <p>EQ.2: the tube is simulated by automatic generation of solid elements, similarly to TYPE = 1 above.</p> |
| VISC | Artificial viscosity multiplier (VISC > 0.0); see Remarks. |
| CFL | Stability factor (CFL > 0.0); see Remarks. |
| DAMP | Linear damping (DAMP ≥ 0.0); see Remarks. |
| BND <i>i</i> | <p>Left/right boundary condition:</p> <p>EQ.0.0: closed tube end, that is, zero velocity boundary condition</p> <p>EQ.1.0: open tube end, that is, constant pressure boundary condition</p> <p>Left/right tube end is automatically assigned by lowest/highest beam node number on tube.</p> |
| NSHL/NSLD | Number of automatically generated shells/solids on circumference of tube |
| ELFORM | ELFORM for automatically generated shells/solids; see *SECTION_SHELL/SOLID. |
| NIP | Number of through thickness integration points for automatically |

| VARIABLE | DESCRIPTION |
|----------|---|
| | generated shells; see NIP in *SECTION_SHELL. |
| NTHK | Number of solid elements in thickness of tube for automatically generated solids |
| SHRF | Shear correction factor for automatically generated shells; see SHRF in *SECTION_SHELL. |
| BPID | Optional PID given to beam elements when automatically generating shells/solids. |

Remarks:

The pressure tube is modeled with an acoustic approximation of the 1D compressible Euler equations for pipes with varying thickness

$$\begin{aligned}\frac{\partial}{\partial t}(\rho A) + \frac{\partial}{\partial x}(\rho u A) &= 0, \\ \frac{\partial}{\partial t}(\rho u A) + \frac{\partial}{\partial x}(\rho u^2 A + p A) &= p \frac{\partial A}{\partial x}, \\ \frac{\partial}{\partial t}(EA) + \frac{\partial}{\partial x}(u(E + p)A) &= 0,\end{aligned}$$

where $A = A(x, t)$ is the cross sectional area and ρ, p, u , and E are density, pressure, velocity, and energy per unit volume, respectively. The above system is closed under the constitutive relations

$$E = \rho e + \frac{\rho u^2}{2}, \quad p = p(\rho, e),$$

where e is the internal energy per unit mass.

For an isentropic and isothermal flow, the pressure will be proportional to the density, that is,

$$p = c_0^2 \rho,$$

and the energy equation can be dropped. This is a good approximation of the Euler equations for acoustic flows where the state variables are smooth perturbations around a background state. For such flows no shocks will develop over time but may be present from initial/boundary values or source terms.

Assuming small perturbations, linearization around $(\rho_0, p_0, u_0 = 0)$ gives the acoustic approximation

$$\frac{\partial}{\partial t}(A\rho) + \rho_0 \frac{\partial y}{\partial x} = 0,$$

$$\rho_0 \frac{\partial y}{\partial t} + c_0^2 \frac{\partial}{\partial x} (A\rho) = p \frac{\partial A}{\partial x},$$

where $y = Au$. Expressed in y and p we have

$$\begin{aligned} \frac{\partial p}{\partial t} + \frac{\partial \ln A}{\partial t} p + \frac{p_0}{A} \frac{\partial y}{\partial x} &= 0, \\ \frac{\partial y}{\partial t} + A \frac{c_0^2}{p_0} \frac{\partial p}{\partial x} &= 0. \end{aligned}$$

This linearized system is solved using the standard Galerkin finite element method, using piecewise linear basis functions and artificial viscosity. Linear damping is added to model energy losses from friction between the gas and the tube walls. With artificial viscosity and linear damping, the system can be written as

$$\begin{aligned} \frac{\partial p}{\partial t} + \frac{\partial \ln A}{\partial t} p + \frac{p_0}{A} \frac{\partial y}{\partial x} &= \epsilon \frac{\partial^2 p}{\partial x^2} - DAMP \cdot (p - p_0) \\ \frac{\partial y}{\partial t} + A \frac{c_0^2}{p_0} \frac{\partial p}{\partial x} &= \epsilon \frac{\partial^2 y}{\partial x^2}, \end{aligned}$$

where the artificial viscosity is proportional to the maximum initial beam element length, that is,

$$\epsilon = VISC \cdot c_0 \max_i \Delta x_i,$$

Time integration is independent of the mechanical solver and uses a step size less than or equal to the global time step, satisfying a CFL condition

$$\Delta t < \min_i \frac{CFL \cdot \Delta x_i}{\Delta x_i \left| \frac{\partial \ln A}{\partial t} \right| + 3c_0}.$$

*DEFINE_REGION

Purpose: Define a volume of space, optionally in a local coordinate system.

| Default | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | | |

VARIABLE**DESCRIPTION**

| | |
|-----|------------------------|
| XMN | Lower x limit of box |
| YMN | Lower y limit of box |
| ZMN | Lower z limit of box |
| XXM | Upper x limit of box |
| YMX | Upper y limit of box |
| ZMX | Upper z limit of box |

Sphere. Use when TYPE = 1.

| Card 3b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-------|-------|---|---|---|
| Variable | XC1 | YC1 | ZC1 | RMIN1 | RMAX1 | | | |
| Type | R | R | R | R | R | | | |
| Default | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | | | |

VARIABLE**DESCRIPTION**

| | |
|---------------|--|
| XC1, YC1, ZC1 | Coordinates of the center of the sphere |
| RMIN1, RMAX1 | The inner and outer radii of the spherical shell. Set RMIN1 = 0 for a solid sphere |

Cylinder. Use when TYPE = 2.

| Card 3c.1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-----------|-----|-----|-----|-----|-----|-----|-------|-------|
| Variable | XC2 | YC2 | ZC2 | AX2 | AY2 | AZ2 | RMIN2 | RMAX2 |
| Type | F | F | F | F | F | F | F | F |
| Default | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 |

Cylinder. Use when TYPE = 2.

| Card 3c.2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-----------|----------|---|---|---|---|---|---|---|
| Variable | L2 | | | | | | | |
| Type | F | | | | | | | |
| Default | ∞ | | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|---------------|---|
| XC2, YC2, ZC2 | A point on the cylindrical axis |
| AX2, AY2, AZ2 | A vector which defines the direction of the axis of the cylinder |
| RMIN2, RMAX2 | The inner and outer radii of the cylindrical shell. Set RMIN2 = 0 for a solid cylinder. |
| L2 | Length of the cylinder. If L2 = 0.0, an infinite cylinder is defined. Otherwise the cylinder has one end at the point (XC2, YC2, ZC2) and the other at a distance L2 along the axis in the direction of the vector (AX2, AY2, AZ2). |

Ellipsoid. Use when TYPE = 3.

| Card 3d.1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-----------|-----|-----|-----|-----|-----|-----|-----|-----|
| Variable | XC3 | YC3 | ZC3 | AX3 | AY3 | AZ3 | BX3 | BY3 |
| Type | F | F | F | F | F | F | F | F |
| Default | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 |

Ellipsoid. Use when TYPE = 3.

| Card 3d.2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-----------|-----|-----|-----|-----|---|---|---|---|
| Variable | BZ3 | RA3 | RB3 | RC3 | | | | |
| Type | F | F | F | F | | | | |
| Default | 0.0 | 0.0 | 0.0 | 0.0 | | | | |

VARIABLE**DESCRIPTION**

XC3, YC3, ZC3

Coordinates of the center of the ellipsoid

AX3, AY3, AZ3

A vector in the direction of the first axis of the ellipsoid (axis **a**)

BX3, BY3, BZ3

A vector, $\tilde{\mathbf{b}}$, in the plain of the first and second axes of the ellipsoid. The third axis of the ellipsoid (axis **c**) will be in the direction of $\mathbf{a} \times \tilde{\mathbf{b}}$ and finally the second axis $\mathbf{b} = \mathbf{c} \times \mathbf{a}$

RA3, RB3, RC3

The semi-axis lengths of the ellipsoid

***DEFINE_SD_ORIENTATION**

Purpose: Define orientation vectors for discrete springs and dampers. These orientation vectors are optional for this element class. Four alternative options are possible. With the first two options, IOP = 0 or 1, the vector is defined by coordinates and is fixed permanently in space. The third and fourth option orients the vector based on the motion of two nodes, so that the direction can change as the line defined by the nodes rotates.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-----|------|------|---|
| Variable | VID | IOP | XT | YT | ZT | NID1 | NID2 | |
| Type | I | I | F | F | F | I | I | |
| Default | 0 | 0 | 0.0 | 0.0 | 0.0 | 0 | 0 | |

VARIABLE**DESCRIPTION**

| | |
|-----|---|
| VID | Orientation vector ID. A unique ID number must be used. |
| IOP | Option (see Remark 1): EQ.0: deflections/rotations are measured and forces/moments applied along the following orientation vector. EQ.1: deflections/rotations are measured and forces/moments applied along the axis between the two spring/damper nodes projected onto the plane normal to the following orientation vector. EQ.2: deflections/rotations are measured and forces/moments applied along a vector defined by the following two nodes. EQ.3: deflections/rotations are measured and forces/moments applied along the axis between the two spring/damper nodes projected onto the plane normal to the a vector defined by the following two nodes. |
| XT | x -value of orientation vector. Define if IOP = 0 or 1. |
| YT | y -value of orientation vector. Define if IOP = 0 or 1. |
| ZT | z -value of orientation vector. Define if IOP = 0 or 1. |

| VARIABLE | DESCRIPTION |
|-----------------|------------------------------------|
| NID1 | Node 1 ID. Define if IOP = 2 or 3. |
| NID2 | Node 2 ID. Define if IOP = 2 or 3. |

Remarks:

1. **Orientation Vectors.** The orientation vectors defined by options 0 and 1 are fixed in space for the duration of the simulation. Options 2 and 3 allow the orientation vector to change with the motion of the nodes. Generally, the nodes should be members of rigid bodies, but this is not mandatory. When using nodes of deformable parts to define the orientation vector, care must be taken to ensure that these nodes will not move past each other. If this happens, the direction of the orientation vector will immediately change with the result that initiate severe instabilities can develop.

***DEFINE_SET_ADAPTIVE**

Purpose: To control the adaptive refinement level by element or part set.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|--------|---------|---|---|---|---|
| Variable | SETID | STYPE | ADPLVL | ADPSIZE | | | | |
| Type | I | I | I | F | | | | |
| Default | none | none | none | none | | | | |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| SETID | Element set ID or part set ID |
| STYPE | Set type for SETID: 1-element set 2-part set |
| ADPLVL | Adaptive refinement level for all elements in SETID set. |
| ADSIZE | Minimum element size to be adapted based on element edge length for all elements in SETID set. |

Remarks:

1. This option is for 3D-shell h-adaptivity only at the present time.
2. The order of defining refinement level for any elements is *CONTROL_ADAPTIVE and *DEFINE_BOX_ADAPTIVE.
3. If there are multiple definitions of refinement level or element size for any elements, the latter one will be used.

*DEFINE_SPH_ACTIVE_REGION

Purpose: The purpose of this keyword is to increase the efficiency of the SPH method's neighborhood search algorithm by specifying an *active region*. All SPH elements located outside of the active region are deactivated. This card supports active regions consisting of the volume bounded by two closed surfaces (boxes, centered cylinders, and centered spheres are currently supported). Once the SPH particle is deactivated, it will stay inactive.

Card Summary:

Card 1. This card is required.

| | | | | | | | |

Sphere Radii Card. This card is included if STYPE = 2.

| Card 2c.2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-----------|------|------|---|---|---|---|---|---|
| Variable | RMIN | RMAX | | | | | | |
| Type | F | F | | | | | | |
| Default | none | none | | | | | | |

VARIABLE

DESCRIPTION

X0, Y0, Z0

The spheres' center.

RMIN

Radius of the interior sphere

RMAX

Radius of the outer sphere

***DEFINE_SPH_DE_COUPLING_{OPTION}**

Purpose: Define a penalty based contact. This option is to be used for the node to node contacts to couple the SPH solver and the discrete element sphere (DES) solver.

The available options include:

<BLANK>

ID

ID Card. Additional card for ID keyword option.

| Card ID | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---------|---|---|---|---|---|---|
| Variable | DID | HEADING | | | | | | |
| Type | I | A80 | | | | | | |
| Default | none | none | | | | | | |

SPH Part Cards. Include as many of this card as desired. Input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|--------|--------|-------|-------|--------|---|
| Variable | SPHID | DESID | SPHTYP | DESTYP | PFACT | DFACT | SPHBOX | |
| Type | I | I | I | I | F | F | I | |
| Default | none | none | none | none | 1.0 | 0. | none | |

VARIABLE**DESCRIPTION**

| | |
|---------|--|
| DID | Definition ID. This must be a unique number. |
| HEADING | Definition descriptor. It is suggested that unique descriptions be used. |
| SPHID | SPH part or part set ID. |
| DESID | DES part or part set ID. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| SPHTYP | SPH part type: EQ.0: Part set ID, EQ.1: Part ID. |
| DESTYP | DES part type: EQ.0: Part set ID, EQ.1: Part ID. |
| PFACT | Penalty scale factor |
| DFACT | Penalty scale factor for contact damping coefficient |
| SPHBOX | BOX ID for SPH parts, See Remarks. |

Remarks:

SPHBOX is used to define the box IDs for the SPH parts. Only the particles inside the boxes are defined for the node to node contacts.

*DEFINE

*DEFINE_SPH_INJECTION

*DEFINE_SPH_INJECTION

Purpose: This keyword injects SPH elements from user defined grid points.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|-----|-----|-----|------|---|
| Variable | PID | NSID | CID | VX | VY | VZ | AREA | |
| Type | I | I | I | F | F | F | F | |
| Default | none | none | none | 0.0 | 0.0 | 0.0 | 0.0 | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------------------|---|---|---|---|---|---|
| Variable | TBEG | TEND | | | | | | |
| Type | F | F | | | | | | |
| Default | 0.0 | 10 ²⁰ | | | | | | |

VARIABLE

DESCRIPTION

| | |
|------------|--|
| PID | Part ID of newly generated SPH elements. |
| NSID | Node set ID. Nodes are used for initial injection position for the SPH elements. |
| CID | Local coordinate system ID; see *DEFINE_COORDINATE_SYSTEM. x and y coordinates define the injection plane, while the z coordinate defines the normal to the injection plane. |
| VX, VY, VZ | Velocity of the inject elements: $\mathbf{v} = (VX, VY, VZ)$ |
| AREA | The area of initial injection surface. The density of injection flow comes from the material models; see *MAT definition. |
| TBEG | Birth time |
| TEND | Death time |

***DEFINE_SPH_TO_SPH_COUPLING**

Purpose: Define a penalty-based, node-to-node contact for particles of SPH parts. Note that this contact type is an alternative to inter-part particle interaction by “particle approximation”; see the field CONT in *CONTROL_SPH and the INTERACTION option of *SECTION_SPH.

Sets of coupling cards:

Each set consists of a Card 1 and may include an additional Card 2. Unless the card following Card 1 contains an “&” in its first column, the optional card is not read. Provide as many sets as necessary. This input terminates at the next keyword (“*”) card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-------|-------|-------|-------|-------|------|
| Variable | SSID | MSID | SSTYP | MSTYP | IBOX1 | IBOX2 | PFACT | SRAD |
| Type | I | I | I | I | I | I | F | F |
| Default | none | none | none | none | none | none | 1.0 | 1.0 |

Optional. The keyword reader identifies this card by an “&” in the first column.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|---|---|---|---|---|---|
| Variable | DFACT | ISOFT | | | | | | |
| Type | F | I | | | | | | |
| Default | 0.0 | 0 | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|------|-----------------------------|
| SSID | Slave part or part set ID. |
| MSID | Master part or part set ID. |

| | |
|-------|--|
| SSTYP | Slave part type: EQ.0: Part set ID, EQ.1: Part ID. |
| MSTYP | Master part type: EQ.0: Part set ID, EQ.1: Part ID. |
| IBOX1 | Box ID for slave parts; see Remark 1 . |
| IBOX2 | Box ID for master parts; see Remark 1 . |
| PFACT | Penalty scale factor; see Remark 2 . |
| SRAD | Scale factor for nodes to nodes contact criteria; see Remark 3 . |
| DFACT | Penalty scale factor for contact damping coefficient; see Remark 3 . |
| ISOFT | Soft constraint option: EQ.0: penalty formulation (default) EQ.1: soft constraint formulation The soft constraint may be necessary if the material constants of the parts in contact have a wide variation in the elastic bulk moduli. In the soft constraint option, the interface stiffness is based on the nodal mass and the global time step size. |

Remarks:

- Contact Particles.** IBOX1 and IBOX2 are used to define the box IDs for the slave parts and the master parts respectively. Only the particles inside the boxes are defined for the node to node contacts.
- Impact Velocity.** For High Velocity Impact problems, a smaller value ranging from 0.01 to 1.0e-4 for the PFACT field is recommended. A value ranging from 0.1 to 1 is recommended for low velocity contact between two SPH parts.
- Contact Detection.** Contact between two SPH particles from different parts is detected when the distance of two SPH particles I and J is less than $SRAD \times (h_I + h_J)/2.0$. If $SRAD < 0$, the contact distance is based on the nodal volumes instead of the smoothing lengths: $SRAD \times (\sqrt[3]{V_I} + \sqrt[3]{V_J})/2.0$.

4. **DFACT.** The default value, $DFACT = 0.0$, is recommended. For $DFACT > 0.0$, interaction between SPH parts includes a viscous effect, providing some stickiness similar to the particle approximation invoked when $CONT = 0$ in ***CONTROL_SPH**. At present, no recommendation can be given for a value of **DFACT** other than the value should be less than 1.0.

***DEFINE_SPOTWELD_FAILURE_{OPTION}**

The available options are

<BLANK>

ADD

PID

Purpose: Define spot weld failure data for the failure criterion developed by Lee and Balur (2011). This card provides the failure data for OPT = 10 on *MAT_SPOTWELD. It is available for spot welds consisting of beam elements, solid elements, or solid assemblies.

*DEFINE_SPOTWELD_FAILURE requires that the weld nodes be tied to shell elements using tied constraint based contact options:

1. For beam element welds, only *CONTACT_SPOTWELD is valid.
2. For solid element welds or solid assembly welds, valid options are the following:

*CONTACT_TIED_SURFACE_TO_SURFACE

*CONTACT_SPOTWELD

*CONTACT_TIED_SHELL_EDGE_TO_SURFACE

Other tied contact types cannot be used.

The ADD keyword option adds materials to a previously defined spot weld failure data set. The PID option changes the Card 3 input to use part set ID's rather than material ID's.

Card Summary:

Card 1. This card is required.

| | | | | | | | |
|----|-------|-----|-----|-----|-----|-----|-----|
| ID | TFLAG | DC1 | DC2 | DC3 | DC4 | EXN | EXS |
|----|-------|-----|-----|-----|-----|-----|-----|

Card 2. This card is included unless the ADD option is used.

| | | | | | | | |
|------|------|------|--------|--------|--|--|--|
| NAVG | D_SN | D_SS | R_SULT | TSCALE | | | |
|------|------|------|--------|--------|--|--|--|

Card 3a. This card is included if the PID option is used. Include one card for each pair of weld parts associated with the data set. The next keyword ("*") card terminates the keyword.

| | | | | | | | |
|------|------|----|----|--|--|--|--|
| PID1 | PID2 | SN | SS | | | | |
|------|------|----|----|--|--|--|--|

Card 3b. This card is included if the PID option is *not* used. Include one card for each material associated with the data set. The next keyword ("*") card terminates the keyword.

| | | | | | | | |
|-----|----|----|--|--|--|--|--|
| MID | SN | SS | | | | | |
|-----|----|----|--|--|--|--|--|

Data Card 1. This card contains the data set’s ID and the first 7 parameters. When the ADD option is active *leave the 7 parameters blank*.

| | | | | | | | | |

| Default | none | Rem 2 | Rem 2 | | | | | |

VARIABLE**DESCRIPTION**

| | |
|-----|---|
| MID | Material ID number of welded shell material |
| SN | Static normal strength of material MID. $S_{n,stat}$. See Remark 2 . |
| SS | Static shear strength of material MID, $S_{s,stat}$. See Remark 2 . |

Remarks:

1. **Failure Model.** This stress based failure model, which was developed by Yung-Li Lee and Santosh Balur (2011) of FCA, compares nominal stress to dynamical strengths for the weld. The weld fails when the stresses are outside of the failure surface defined as

$$\left(\frac{s_n}{S_{n,dyn}}\right)^{n_n} + \left(\frac{s_s}{S_{s,dyn}}\right)^{n_s} = 1,$$

where s_n and s_s are nominal stresses in the normal and tangential directions, $S_{n,dyn}$ and $S_{s,dyn}$ are dynamical strengths in the normal and tangential directions, and n_n and n_s are the exponential factors EXN and EXS, respectively. The nominal stresses are defined as

$$s_n = \frac{P_n}{Dct}, \quad s_s = \frac{P_s}{Dct},$$

where P_n and P_s are the loads carried by the weld in the normal and tangential directions, D is the weld diameter, c is scale factor TSCALE, and t is the thickness of the welded sheets calculated according to the value of TFLAG. The dynamical strength terms in the denominator are load-rate dependent and are derived from static strength:

$$S_{n,dyn} = S_{n,stat} \left[c_1 + c_2 \left(\frac{\dot{P}_n}{c_4} \right) + c_3 \log \left(\frac{\dot{P}_n}{c_4} \right) \right]$$

$$S_{s,dyn} = S_{s,stat} \left[c_1 + c_2 \left(\frac{\dot{P}_s}{c_4} \right) + c_3 \log \left(\frac{\dot{P}_s}{c_4} \right) \right]$$

where the constants c_1 to c_4 are the input in the fields DC1 to DC4, \dot{P}_n and \dot{P}_s are the load rates, and $S_{n,stat}$ and $S_{s,stat}$ are the static strengths of the welded sheet materials (see [Remark 2](#)).

2. **Static Strengths.** When two different materials are welded, the material having the smaller normal strength (SN) determines the static strengths used for the weld. Materials that do not have SN and SS values default to D_SN and D_SS from Card 2.

If R_SULT is defined on Card 2 and the PID keyword option is not used, then D_SN and D_SS are interpreted to be reference values of the normal and shear static strength, and the SN field on Card 3 is interpreted as a material specific ultimate strength. These values are then used to calculate material specific strength values by

$$S_{n,stat} = S_{n,ref} \left(\frac{S_u}{S_{u,ref}} \right), \quad S_{s,stat} = S_{s,ref} \left(\frac{S_u}{S_{u,ref}} \right)$$

where $S_{n,ref}$, $S_{s,ref}$, and $S_{u,ref}$ are D_SN, D_SS, and R_SULT on Card 2, and S_u is SN on Card 3. The SS values are ignored.

If the PID keyword option is used, then R_SULT is ignored, and SN and SS are static strength values.

3. **Default Values.** The default values for DC1 to DC4, and EXN and EXS are based on the work Chao, Wang, Miller and Zhu (2010). and Wang, Chao, Zhu, and Miller (2010). These parameters are unitless except for DC4 which has units of force per unit time. The default value of 0.1 has units of MN/sec.
4. **Load Rate.** The load rate, \dot{P} , can be time averaged to reduce the effect of high frequency oscillations on the dynamic weld strength. NAVG is the number of terms in the time average.

*DEFINE

*DEFINE_SPOTWELD_FAILURE_RESULTANTS

*DEFINE_SPOTWELD_FAILURE_RESULTANTS

Purpose: Define failure criteria between part pairs for predicting spot weld failure. This table is implemented for *solid* element spot welds, which are used with the tied, constraint based, contact option: *CONTACT_TIED_SURFACE_TO_SURFACE. *Note that other tied contact types cannot be used.* The input in this section continues until then next "*" card is encountered. Default values are used for any part ID pair that is not defined. Only one table can be defined. See *MAT_SPOTWELD where this option is used whenever *OPT* = 7.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|-----|-----|---------|---------|---|---|---|
| Variable | ID | DSN | DSS | DLCIDSN | DLCIDSS | | | |
| Type | I | F | F | I | I | | | |
| Default | 0 | 0.0 | 0.0 | 0 | 0 | | | |

Failure Cards. Provide as many as necessary. The next keyword ("*") card terminates the table definition.

| Card 2... | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-----------|-------|-------|------|------|----------|----------|---|---|
| Variable | PID_I | PID_J | SNIJ | SSIJ | LCIDSNIJ | LCIDSSIJ | | |
| Type | I | I | F | F | I | I | | |
| Default | none | none | 0.0 | 0.0 | 0 | 0 | | |

VARIABLE

DESCRIPTION

| | |
|---------|--|
| ID | Identification number. Only one table is allowed. |
| DSN | Default value of the normal static stress at failure. |
| DSS | Default value of the transverse static stress at failure. |
| DLCIDSN | Load curve ID defining a scale factor for the normal stress as a function of strain rate. This factor multiplies DSN to obtain the failure value at a given strain rate. |

| VARIABLE | DESCRIPTION |
|----------|---|
| DLCIDSS | Load curve ID defining a scale factor for static shear stress as a function of strain rate. This factor multiplies DSN to obtain the failure value at a given strain rate. |
| PID_I | Part ID I. |
| PID_J | Part ID J. |
| SNIJ | The maximum axial stress at failure between parts I and J. The axial stress is computed from the solid element stress resultants, which are based on the nodal point forces of the solid element. |
| DSSIJ | The maximum shear stress at failure between parts I and J. The shear stress is computed from the solid element stress resultants, which are based on the nodal point forces of the solid element. |
| LCIDSNIJ | Load curve ID defining a scale factor for the normal stress as a function of strain rate. This factor multiplies SNIJ to obtain the failure value at a given strain rate. |
| LCIDSSIJ | Load curve ID defining a scale factor for static shear stress as a function of strain rate. This factor multiplies SSIJ to obtain the failure value at a given strain rate. |

Remarks:

The stress based failure model, which was developed by *Toyota Motor Corporation*, is a function of the peak axial and transverse shear stresses. The entire weld fails if the stresses are outside of the failure surface defined by:

$$\left(\frac{\sigma_{rr}}{\sigma_{rr}^F}\right)^2 + \left(\frac{\tau}{\tau^F}\right)^2 - 1 = 0$$

where σ_{rr}^F and τ^F are specified in the above table by part ID pairs. LS-DYNA automatically identifies the part ID of the attached shell element for each node of the spot weld solid and checks for failure. If failure is detected the solid element is deleted from the calculation.

If the effects of strain rate are considered, then the failure criteria becomes:

$$\left[\frac{\sigma_{rr}}{f_{dsn}(\dot{\epsilon}^p)\sigma_{rr}^F}\right]^2 + \left[\frac{\tau}{f_{dss}(\dot{\epsilon}^p)\tau^F}\right]^2 - 1 = 0$$

***DEFINE_SPOTWELD_MULTISCALE**

Purpose: Associate beam sets with multi-scale spot weld types for modeling spot weld failure via the multi-scale spot weld method.

Spot Weld/Beam Set Association Cards. Provide as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | TYPE | BSET | TYPE | BSET | TYPE | BSET | TYPE | BSET |
| Type | I | I | I | I | I | I | I | I |
| Default | none |

VARIABLE**DESCRIPTION**

| | |
|------|---|
| TYPE | MULTISCALE spot weld type to use. See *INCLUDE_SPOTWELD_MULTISCALE |
| BSET | Beam set which uses this multi-scale spot weld type for failure modeling. |

Remarks:

See *INCLUDE_MULTISCALE_SPOTWELD for a detailed explanation of this capability.

***DEFINE_SPOTWELD RUPTURE_PARAMETER**

Purpose: Define a parameter by part ID for shell elements attached to spot weld *beam* elements using the constrained contact option: *CONTACT_SPOTWELD. *This table will not work with other contact types.* Only one table is permitted in the problem definition. Data, which is defined in this table, is used by the stress based spot weld failure model developed by *Toyota Motor Corporation*. See *MAT_SPOTWELD where this option is activated by setting the parameter OPT to a value of 9. This spot weld failure model is a development of *Toyota Motor Corporation*.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|---|---|---|---|---|---|---|
| Variable | PID | | | | | | | |
| Type | I | | | | | | | |

| Type | F | F | F | F | F | F | | F |

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|----|---|---|---|--------|
| Variable | C21 | C22 | C23 | N2 | | | | SIG_NF |
| Type | F | F | F | F | | | | F |

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|-------|-------|-------|---|------|
| Variable | LCDPA | LCDPM | LCDPS | LCDNA | LCDNM | LCDNS | | NSMT |
| Type | I | I | I | I | I | I | | I |
| Default | 0 | 0 | 0 | 0 | 0 | 0 | | 0 |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| PID | Part ID for the attached shell. |
| C11-N2 | Parameters for model, see Remarks below. |
| SIG_PF | Nugget pull-out stress, σ_p |
| SIG_NF | Nugget fracture stress, σ_F . |
| LCDPA | Curve ID defining dynamic scale factor of spot weld axial load rate for nugget pull-out mode. |
| LCDPM | Curve ID defining dynamic scale factor of spot weld moment load rate for nugget pull-out mode. |
| LCDPS | Curve ID defining dynamic scale factor of spot weld shear load rate for nugget pull-out mode. |
| LCDNA | Curve ID defining dynamic scale factor of spot weld axial load rate for nugget fracture mode. |
| LCDNM | Curve ID defining dynamic scale factor of spot weld moment load rate for nugget fracture mode. |
| LCDNS | Curve ID defining dynamic scale factor of spot weld shear load rate for nugget fracture mode. |
| NSMT | The number of time steps used for averaging the resultant rates for the dynamic scale factors. |

Remarks:

This failure model incorporates two failure functions, one for nugget pull-out and the other for nugget fracture. The nugget pull-out failure function is

$$F_p = \frac{C11 \times \frac{A}{D^{N11}} + C12 \times \frac{M}{D^{N12}} + C13 \times \frac{S}{D^{N13}}}{\sigma_p \left[1 + \left(\frac{\dot{\epsilon}^p}{C} \right)^{1/p} \right]}$$

where A , M , and S are the axial force, moment, and shear resultants respectively, D is the spot weld diameter, and the Cowper-Symonds coefficients are from the attached shell material model. If the Cowper-Symonds coefficients aren't specified, the term within the square brackets, [], is 1.0. The fracture failure function is

$$F_n = \frac{\sqrt{(C21 \times A + C22 \times M)^2 + 3(C23 \times S)^2}}{D^{N2} \sigma_F \left[1 + \left(\frac{\dot{\epsilon}^p}{C} \right)^{1/p} \right]}$$

When the load curves for the rate effects are specified, the failure criteria are

$$F_p = \frac{C11 \times f_{dpa}(\dot{A}) \times \frac{A}{D^{N11}} + C12 \times f_{dpa}(\dot{M}) \times \frac{M}{D^{N12}} + C13 \times f_{dpa}(\dot{S}) \times \frac{S}{D^{N13}}}{\sigma_P}$$

$$F_n = \frac{\sqrt{[C21 \times f_{dna}(\dot{A}) \times A + C22 \times f_{dnm}(\dot{M}) \times M]^2 + 3[C23 \times f_{dns}(\dot{S}) \times S]^2}}{D^{N2} \sigma_F}$$

where f is the appropriate load curve scale factor. The scale factor for each term is set to 1.0 for when no load curve is specified. No extrapolation is performed if the rates fall outside of the range specified in the load curve to avoid negative scale factors. A negative load curve ID designates that the curve abscissa is the \log_{10} of the resultant rate. This option is recommended when the curve data covers several orders of magnitude in the resultant rate. Note that the load curve dynamic scaling replaces the Cowper-Symonds model for rate effects.

Failure occurs when either of the failure functions is greater than 1.0.

***DEFINE_SPOTWELD RUPTURE STRESS**

Purpose: Define a static stress rupture table by part ID for shell elements connected to spot weld *beam* elements using the constrained contact option: *CONTACT_SPOTWELD. *This table will not work with other contact types.* Only one table is permitted in the problem definition. Data, which is defined in this table, is used by the stress based spot weld failure model developed by *Toyota Motor Corporation*. See *MAT_SPOTWELD where this option is activated by setting the parameter *OPT* to a value of 6.

Part Cards. Define rupture stresses part by part. The next keyword (“*”) card terminates this input.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-------|--------|-------|---|---|---|---|
| Variable | PID | SRSIG | SIGTAU | ALPHA | | | | |
| Type | I | F | F | F | | | | |

VARIABLE**DESCRIPTION**

| | |
|-------|---|
| PID | Part ID for the attached shell. |
| SRSIG | Axial (normal) rupture stress, σ_{rr}^F . |
| SRTAU | Transverse (shear) rupture stress, τ^F . |
| ALPHA | Scaling factor for the axial stress as defined by Toyota. The default value is 1.0. |

Remarks:

The stress based failure model, which was developed by *Toyota Motor Corporation*, is a function of the peak axial and transverse shear stresses. The entire weld fails if the stresses are outside of the failure surface defined by:

$$\left(\frac{\sigma_{rr}}{\sigma_{rr}^F}\right)^2 + \left(\frac{\tau}{\tau^F}\right)^2 - 1 = 0$$

where σ_{rr}^F and τ^F are specified in the above table by part ID. LS-DYNA automatically identifies the part ID of the attached shell element for each node of the spot weld beam and independently checks each end for failure. If failure is detected in the end attached to the shell with the greatest plastic strain, the beam element is deleted from the calculation.

If the effects of strain rate are considered, then the failure criteria becomes:

$$\left[\frac{\sigma_{rr}}{\sigma_{rr}^F(\dot{\epsilon}^p)} \right]^2 + \left[\frac{\tau}{\tau^F(\dot{\epsilon}^p)} \right]^2 - 1 = 0$$

where $\sigma_{rr}^F(\dot{\epsilon}^p)$ and $\tau^F(\dot{\epsilon}^p)$ are found by using the Cowper and Symonds model which scales the static failure stresses:

$$\sigma_{rr}^F(\dot{\epsilon}^p) = \sigma_{rr}^F \left[1 + \left(\frac{\dot{\epsilon}^p}{C} \right)^{1/p} \right]$$

$$\tau^F(\dot{\epsilon}^p) = \tau^F \left[1 + \left(\frac{\dot{\epsilon}^p}{C} \right)^{1/p} \right]$$

where $\dot{\epsilon}^p$ is the average plastic strain rate which is integrated over the domain of the attached shell element, and the constants p and C are uniquely defined at each end of the beam element by the constitutive data of the attached shell. The constitutive model is described in the material section under keyword: *MAT_PIECEWISE_LINEAR_PLASTICITY.

The peak stresses are calculated from the resultants using simple beam theory.

$$\sigma_{rr} = \frac{N_{rr}}{A} + \frac{\sqrt{M_{rs}^2 + M_{rt}^2}}{\alpha Z} \quad \tau = \frac{M_{rr}}{2Z} + \frac{\sqrt{N_{rs}^2 + N_{rt}^2}}{A}$$

where the area and section modulus are given by:

$$A = \pi \frac{d^2}{4}$$

$$Z = \pi \frac{d^3}{32}$$

and d is the diameter of the spot weld beam.

*DEFINE

*DEFINE_STAGED_CONSTRUCTION_PART

*DEFINE_STAGED_CONSTRUCTION_PART_{OPTION}

Available options include:

<BLANK>

SET

Purpose: Staged construction. This keyword offers a simple way to define parts that are removed (e.g., during excavation), added (e.g., new construction) and used temporarily (e.g., props) during the analysis. Available for solid, shell, and beam element parts.

Part Cards. Provide as many as necessary. This input terminates at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|------|------|---|---|---|---|---|
| Variable | PID/PSID | STGA | STGR | | | | | |
| Type | I | I | I | | | | | |
| Default | none | none | none | | | | | |

VARIABLE

DESCRIPTION

| | |
|------|---|
| PID | Part ID (or Part Set ID for the SET keyword option) |
| STGA | Construction stage at which part is added. See Remark 1 . |
| STGR | Construction stage at which part is removed. See Remark 1 . |

Remarks:

- Adding and Removing Stages.** Used with *DEFINE_CONSTRUCTION_STAGES (defines the meaning of stages STGA and STGR) and *CONTROL_STAGED_CONSTRUCTION. If STGA = 0, the part is present at the start of the analysis. If STGR = 0, the part is still present at the end of the analysis. Examples:
 - Soil that is excavated would have STGA = 0 but STGR > 0
 - New construction would have STGA > 0 and STGR = 0

- c) Temporary works would have $STGA > 0$, $STGR > STGA$.
2. **Construction Models.** This is a convenience feature that reduces the amount of input data needed for many typical construction models. Internally, LS-DYNA automatically creates *LOAD_REMOVE_PART, *LOAD_GRAVITY_PART and *LOAD_STIFFEN_PART referencing the same PID and using the default gravity and pre-construction stiffness factors from *CONTROL_STAGED_CONSTRUCTION. If the same PID is also referenced in the input file by any of the three types of *LOAD cards mentioned above, the load curves entered on the *LOAD cards will override the STGA, STGR inputs on *DEFINE_STAGED_CONSTRUCTION_PART.
 3. **Use of Ramp Time.** Ramp time ATR on *DEFINE_CONSTRUCTION_STAGES is intended to reduce dynamic effects that would occur if loading or stresses were changed suddenly. It applies to gravity loading during addition and removal of parts, i.e. *LOAD_GRAVITY_PART automatically gets ramped up to its full value during the first ATR of the stage when a part is added (STGA), and ramped down to zero during the first ATR of the stage when a part is removed (STGR). For the stiffness, strength and stresses, ATR applies during removal of a part but not during addition. Starting from R11, when a part is added, the stiffness jumps immediately to its full value at the start of STGA. This behavior is different from versions R10 and previous, where ATR was also applied to stiffness during part addition. The disadvantage of the R10 behavior was that significant deformations could occur before the part reached its full stiffness.

*DEFINE

*DEFINE_STOCHASTIC_ELEMENT_OPTION

*DEFINE_STOCHASTIC_ELEMENT_OPTION

Options:

SOLID_VARIATION for solid elements

SHELL_VARIATION for shell elements

Purpose: Define the stochastic variation in the yield stress, damage/failure models, density, and elastic moduli for solid material models with the STOCHASTIC keyword option on an element basis. This keyword works currently with materials 10, 15, 24, 81, and 98. This option overrides values assigned by *DEFINE_STOCHASTIC_VARIATION.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|------|-------|------|---|---|---|
| Variable | IDE | VARSY | VARF | VARRO | VARE | | | |
| Type | I | F | F | F | F | | | |
| Default | none | 0.0 | 0.0 | 0.0 | 0.0 | | | |

VARIABLE

DESCRIPTION

| | |
|-------|--|
| IDE | Element ID |
| VARSY | The yield stress and its hardening function are scaled by 1.0+VARSY. |
| VARF | The failure criterion is scaled by 1.0+VARF |
| VARRO | The density is scaled by 1.0+VARRO. This is intended to be used with topology optimization. This option is not available for shell elements. |
| VARE | The elastic moduli are scaled by 1.0+VARE. This is intended to be used with topology optimization. |

***DEFINE_STOCHASTIC_VARIATION**

Purpose: Define the stochastic variation in the yield stress and damage/failure models for material models with the STOCHASTIC keyword option. This keyword currently works with materials 10, 15, 24, 81, 98 and the shell version of material 123.

|----------|------|---|---|---|---|---|---|---|
| Variable | LCID | | | | | | | |
| Type | I | | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| R1, R2, R3 | Real values to define the stochastic distribution. See below. |
| LCID | Curve ID defining the stochastic distribution. See below. |

Remarks:

Each integration point x_g in the parts specified by PID is assigned the random scale factors R_S and R_F that are applied to the values calculated by the material model for the yield stress and failure strain.

$$\begin{aligned}\sigma_y &= R_S(x_g)\sigma_y(\bar{\epsilon}^p, \dots) \\ \bar{\epsilon}_{\text{FAIL}}^p &= R_F(x_g)\bar{\epsilon}_{\text{FAIL}}^p(\dot{\epsilon}, \bar{\epsilon}^p, \dots)\end{aligned}$$

The scale factors vary spatially over the model according to the chosen statistical distributions defined in this section and are independent of time. The scale factors may be completely correlated or uncorrelated with the default being completely correlated since the failure strain is generally reduced as the yield stress increases. The scale factors R_S and R_F may be stored as extra history variables as follows:

| Material Model | History Variable # for R_S | History Variable # for R_F |
|-----------------------|--|--|
| 10 | 5 | 6 |
| 15 | 7 | 8 |
| 24 | 6 | 7 |
| 81 | 6 | 7 |
| 98 | 7 | 8 |
| 123 (shells only) | 6 | 7 |

The user is responsible for defining the distributions so that they are physically meaningful and are restricted to a realistic range. Since neither the yield stress nor the failure strain may be negative, for example, the minimum values of the distributions must always be greater than zero.

The probability that a particular value R will occur defines the *probability distribution function*, $P(R)$. Since a value must be chosen from the distribution, the integral from the minimum to the maximum value of R of the probability distribution function must be 1.0,

$$\int_{R_{\text{MIN}}}^{R_{\text{MAX}}} P(R)dR = 1.0 .$$

Another way to characterize a distribution is the *cumulative distribution function* $C(R)$ which defines the probability that a value will lie between R_{MIN} and R ,

$$C(R) = \int_{R_{\text{MIN}}}^R P(\hat{R}) d\hat{R}.$$

By definition $C(R_{\text{MIN}}) = 0$ and $C(R_{\text{MAX}}) = 1$. An inverse cumulative probability function D gives the number for a cumulative probability of $C(R)$,

$$D(C(R)) = R.$$

A random variable satisfying the probability distribution function $P(R)$ can be generated from a sequence of uniformly distributed numbers, \hat{R}_I , for $I = 1, N$, using the inverse cumulative distribution function D as

$$R_I = D(\hat{R}_I).$$

The scale factors for the yield stress and the failure strain may be generated using the same value of \hat{R}_I for both (ICOR = 0) or by using independent values each one (ICOR = 1). If the same values are used, there is perfect correlation, and the failure strain scale factor becomes an implicit value of yield stress scale factor.

VAR = 0. No Scaling.

The corresponding yield stress or failure strain is not scaled.

VAR = 1. Scaling from Uniform Distribution

A uniform distribution is specified by setting VAR = 1. The input variable R1 is interpreted as R_{MIN} and R2 as R_{MAX} . If R1 = R2, then the yield stress or failure strain will be scaled by R1.

When using the uniform random distribution, the probability of a particular value is given by

$$P(R) = \frac{1}{R_{\text{MAX}} - R_{\text{MIN}}}$$

and the cumulative probability function is given by

$$C(R) = \frac{R - R_{\text{MIN}}}{R_{\text{MAX}} - R_{\text{MIN}}}.$$

VAR = 2. Gaussian Distribution

The Gaussian distribution, VAR = 2, is smoothly varying with a peak at μ and 63 percent of the values occurring within the interval of one standard deviation σ , $[\mu - \sigma, \mu + \sigma]$. The input parameter R1 is interpreted as the mean, μ , while R2 is interpreted as the standard deviation, σ . There is a finite probability that the values of R will be outside of the range that are physically meaningful in the scaling process, and

R3 which is interpreted as δ restricts the range of R to $[\mu - \delta, \mu + \delta]$ The resulting truncated Gaussian distribution is rescaled such that,

$$D(\mu + \delta) = 1 .$$

VAR = 3 or 4. Distribution from a Load Curve

The user may directly specify the probability distribution function or the cumulative probability distribution function with *DEFINE_CURVE by setting VAR = 3 or VAR = 4, respectively, and then specifying the required curve ID on the next data card.

Stochastic variations may be used simultaneously with the heat affected zone (HAZ) options in LS-DYNA (see *DEFINE_HAZ_PROPERTIES). The effect of the scale factors from stochastic variation and HAZ options are multiplied together to scale the yield stress and failure strain,

$$\begin{aligned}\sigma_y &= R_S(x_g)R_S^{\text{HAZ}}\sigma_y(\bar{\epsilon}^p, \dots) \\ \bar{\epsilon}_{\text{FAIL}}^p &= R_F(x_g)R_F^{\text{HAZ}}\bar{\epsilon}_{\text{FAIL}}^p(\dot{\epsilon}, \bar{\epsilon}^p, \dots).\end{aligned}$$

***DEFINE_TABLE**

Purpose: To interpolate from point data a continuously indexed family of nonintersecting curves. The family of curves, \mathcal{F} , consists of x-y curves, $f_s(x)$, indexed by a parameter, s .

$$\mathcal{F} = \{f_s(x) | \forall s \in [s_{\min}, s_{\max}]\}.$$

The interpolation is built up by sampling functions in \mathcal{F} at discrete parameter values, s_i ,

$$f_{s_i}(x) \in \mathcal{F}.$$

The points, s_i , are input to LS-DYNA on the data cards for the *DEFINE_TABLE keyword. LS-DYNA requires that they be ordered from least to greatest. The curves, $f_{s_i}(x)$, must be defined as lists of (x,y) pairs in a collection of *DEFINE_CURVE sections that directly follow the *DEFINE_TABLE section. Each *DEFINE_CURVE section is paired to its corresponding s_i value by list position (and not load curve ID, for that see *DEFINE_TABLE_2D).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|------|---|---|---|---|---|
| Variable | TBID | SFA | OFFA | | | | | |
| Type | I | F | F | | | | | |
| Default | none | 1. | 0. | | | | | |

Points Cards. Place one point per card. The values must be in ascending order. Input is terminated when a “*DEFINE_CURVE” keyword card is found.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|---|---|---|---|---|---|
| Variable | VALUE | | | | | | | |
| Type | F | | | | | | | |
| Default | 0.0 | | | | | | | |

Include one *DEFINE_CURVE input section here for each point defined above. The i^{th} *DEFINE_CURVE card contains the curve at the i^{th} *DEFINE_TABLE value.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| TBID | Table ID. Tables and Load curves may not share common ID's. LS-DYNA allows load curve ID's and table ID's to be used interchangeably. |
| SFA | Scale factor for VALUE. |
| OFFA | Offset for VALUE, see explanation below. |
| VALUE | Load curve will be defined corresponding to this value, e.g., this value could be a strain rate, see purpose above. |

Motivation:

This capability was implemented with strain-rate dependent stress-strain relations in mind. To define such a function, the first step is to tabulate stress-strain curves at known strain-rate values. Then, the list of strain-rates is written in ascending order to the data cards following *DEFINE_TABLE. Following *DEFINE_TABLE, the tabulated stress-strain curves must be input to LS-DYNA as a set of *DEFINE_CURVE sections ordered so that the i^{th} curve corresponds to the i^{th} strain-rate point. This section is structured as:

```

*DEFINE_TABLE
strain-rate point 1
strain-rate point 2
      :
strain-rate point n
*DEFINE_CURVE
[stress-strain curve at strain-rate 1]
*DEFINE_CURVE
[stress-strain curve at strain-rate 2]
      :
*DEFINE_CURVE
[stress-strain curve at strain-rate n]

```

Details, Features and Limitations:

1. All the curves in a table must start from the same abscissa value and end at the same abscissa value. This limitation is necessary to avoid slow indirect addressing in the inner loops used in the constitutive model stress evaluation. Curves must not intersect except at the origin and end points.

2. Each curve may have unique spacing and an arbitrary number of points in its definition.
3. All the curves in a table must share the same value of LCINT.
4. In most applications, curves can only be extrapolated in one direction, that is, to the right of the last data point. An example would be curves representing effective stress vs. effective plastic strain. For cases when extrapolation is only to the right, the curves comprising a table are allowed to intersect *only* at their starting point but the curves *and their extrapolations* must not intersect elsewhere.

For other applications in which the curves are extrapolated in both directions, the curves and their extrapolations are not allowed to intersect except at the origin (0,0). An example would be curves representing force vs. change in gage length where negative values are compressive and positive values are tensile.

5. Load curve IDs defined for the table may be referenced elsewhere in the input.
6. No keyword commands may come between *DEFINE_TABLE and the *DEFINE_CURVE commands that feed the table. The set of *DEFINE_CURVE commands must not be interrupted by any other keyword. This coupling between *DEFINE_TABLE and subsequent *DEFINE_CURVE commands is an exception to the general order-independence of the keyword format.
7. VALUE is scaled in the same manner as in *DEFINE_CURVE, i.e.,
$$\text{Scaled value} = \text{SFA} \times (\text{Defined value} + \text{OFFA}).$$
8. Unless stated otherwise in the description of a keyword command that references a table, there is no extrapolation beyond the range of VALUEs defined for the table. For example, if the table VALUE represents strain rate and the calculated strain rate exceeds the last/highest VALUE given by the table, the stress-strain curve corresponding to the last/highest table VALUE will be used.

***DEFINE_TABLE_2D**

Purpose: Define a table. Unlike the *DEFINE_TABLE keyword above, a curve ID is specified for each value defined in the table. This allows the same curve ID to be referenced by multiple tables, and the curves may be defined anywhere in the input file. Other than these differences from *DEFINE_TABLE, the general rules given in the remarks of *DEFINE_TABLE still apply.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|------|---|---|---|---|---|
| Variable | TBID | SFA | OFFA | | | | | |
| Type | I | F | F | | | | | |
| Default | none | 1. | 0. | | | | | |

Points Cards. Place one point per card. The values must be in ascending order. Input is terminated when a “*DEFINE_CURVE” keyword card is found.

| Card 2 | 1 | 2 | 3 | 4 |
|----------|-------|----------|---|---|
| Variable | VALUE | CURVE ID | | |
| Type | F | I | | |
| Default | 0.0 | none | | |

VARIABLE**DESCRIPTION**

| | |
|---------|---|
| TBID | Table ID. Tables and Load curves may not share common ID's. LS-DYNA allows load curve ID's and table ID's to be used interchangeably. |
| SFA | Scale factor for VALUE. |
| OFFA | Offset for VALUE; see remarks for *DEFINE_TABLE. |
| VALUE | Load curve will be defined corresponding to this value. The value could be, for example, a strain rate. |
| CURVEID | Load curve ID. See Remark 1 . |

Remarks:

1. **Curve IDs.** Though generally of no concern to the user, curve CURVEID is automatically duplicated during initialization and the duplicate curve is automatically assigned a unique curve ID. The generated curve IDs used by the table are revealed in d3hsp. It is generally only necessary to know the generated curve IDs when interpreting warning messages about those curves.

***DEFINE_TABLE_3D**

Purpose: Define a three dimensional table. For each value defined below, a table ID is specified. For example, in a thermally dependent material model, the value given below could correspond to temperature for a table ID defining effective stress versus strain curves for a set of strain rate values. Each table ID can be referenced by multiple three dimensional tables, and the tables may be defined anywhere in the input.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|------|---|---|---|---|---|
| Variable | TBID | SFA | OFFA | | | | | |
| Type | I | F | F | | | | | |
| Default | none | 1. | 0. | | | | | |

Points Cards. Place one point per card. The values must be in ascending order. Input is terminated when a “*DEFINE_CURVE” keyword card is found.

| Card 2 | 1 | 2 | 3 | 4 |
|----------|-------|----------|---|---|
| Variable | VALUE | TABLE ID | | |
| Type | F | I | | |
| Default | 0.0 | none | | |

VARIABLE**DESCRIPTION**

| | |
|---------|---|
| TBID | Table ID. Tables and load curves may not share common ID's. LS-DYNA allows load curve ID's and table ID's to be used interchangeably. |
| SFA | Scale factor for VALUE. |
| OFFA | Offset for VALUE, see explanation below. |
| VALUE | Load curve will be defined corresponding to this value, e.g., this value could be a strain rate for example. |
| TABLEID | Table ID. |

Remarks:

1. **Scaling.** VALUE is scaled in the same manner as in *DEFINE_CURVE, that is,
$$\text{Scaled value} = \text{SFA} \times (\text{Defined value} + \text{OFFA}).$$
2. **Extrapolation.** Unless stated otherwise in the description of a keyword command that references a table, there is no extrapolation beyond the range of VALUEs defined for the table. For example, if the table VALUE represents strain rate and the calculated strain rate exceeds the last/highest VALUE given by the table, the stress-strain curve corresponding to the last/highest table VALUE will be used

***DEFINE_TABLE_MATRIX**

Purpose: This is an alternative input format for *DEFINE_TABLE that allows for reading data from an unformatted text file containing a matrix with data separated by comma delimiters. The purpose is to use data saved directly from excel sheets without having to convert it to keyword syntax.

| | | | | | | | | |
|----------|------|----------|---|---|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | TBID | FILENAME | | | | | | |
| Type | I | A70 | | | | | | |

| | | | | | | | | |
|----------|------|------|------|------|------|------|------|------|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | NROW | NCOL | SROW | SCOL | SVAL | OROW | OCOL | OVAL |
| Type | I | I | F | F | F | F | F | F |
| Default | none | none | 1. | 1. | 1. | 0. | 0. | 0. |

VARIABLE**DESCRIPTION**

TBID Table ID. Tables and Load curves may not share common ID's. LS-DYNA allows load curve ID's and table ID's to be used interchangeably.

FILENAME Name of file containing table data (stored as a matrix).

NROW Number of rows in the matrix, same as number of rows in the file FILENAME. A negative value of NROW switches the interpretation of rows and columns in the read matrix, see [Remarks 1 and 2](#).

NCOL Number of columns in the matrix, same as number of data entries per row in the file FILENAME

SROW Scale factor for row data, see [Remark 2](#).

SCOL Scale factor for column data, see [Remark 2](#).

SVAL Scale factor for matrix values, see [Remark 2](#).

| VARIABLE | DESCRIPTION |
|-----------------|--|
| OROW | Offset for row data, see Remark 2 . |
| OCOL | Offset for column data, see Remark 2 . |
| OVAL | Offset for matrix values, see Remark 2 . |

Remarks:

1. **Example.** The use of this keyword allows for inputting a table in form of a matrix from a file, exemplified here by a 4 × 5 matrix.

| | | | | |
|----|-----|-----|-----|-----|
| | C1 | C2 | C3 | C4 |
| R1 | V11 | V12 | V13 | V14 |
| R2 | V21 | V22 | V23 | V24 |
| R3 | V31 | V32 | V33 | V34 |
| ⋮ | ⋮ | ⋮ | ⋮ | ⋮ |

The unformatted file representing this matrix would contain the following data

```

, C1, C2, C3, C4
R1, V11, V12, V13, V14
R2, V21, V22, V23, V24
R3, V31, V32, V33, V34

```

Note that the first entry in the matrix is a dummy and delimited by an initial comma in the file. The keyword card for this matrix is: (TBID = 1000 and the filename is file.txt)

```

*DEFINE_TABLE_MATRIX
1000,file.txt
4,5

```

This is equivalent to using:

```

*DEFINE_TABLE
1000
C1
C2
C3
C4
*DEFINE_CURVE
1001
R1,V11
R2,V21
R3,V31
*DEFINE_CURVE

```

```

1002
R1,V12
R2,V22
R3,V32
*DEFINE_CURVE
1003
R1,V13
R2,V23
R3,V33
*DEFINE_CURVE
1004
R1,V14
R2,V24
R3,V34

```

2. **Scaling, Offsets, and Transposition.** All entries in the matrix can be scaled and offset following the convention for other tables and curves:

$$\text{Scaled Value} = S[\text{ROW/COL}] \times (\text{Value} + O[\text{ROW/COL}])$$

Finally, the matrix can be transposed by setting `NROW` to a negative value. In the example above ([Remark 1](#)) this would mean that

```

*DEFINE_TABLE_MATRIX
1000,file.txt
-4,5

```

is equivalent to using:

```

*DEFINE_TABLE
1000
R1
R2
R3
*DEFINE_CURVE
1001
C1,V11
C2,V12
C3,V13
C4,V14
*DEFINE_CURVE
1002
C1,V21
C2,V22
C3,V23
C4,V24
*DEFINE_CURVE
1003
C1,V31
C2,V32

```

C3, V33

C4, V34

In this case, any scaling applies to the matrix entries before transposing the data, i.e., for row entries the scaled value is

$$\text{Scaled Value} = \text{SROW} \times (R + \text{OROW}),$$

and for column entries

$$\text{Scaled Value} = \text{SCOL} \times (C + \text{OCOL})$$

regardless the sign of TBID.

***DEFINE_TARGET_BOUNDARY**

Purpose: This keyword is used to define the desired boundary of a formed part. This boundary provides the criteria used during blank size development. The definitions associated with this keyword are used, exclusively, by the [*INTERFACE_BLANKSIZE_DEVELOPMENT](#) feature.

Point Cards. Include one card for each point in the curve. These points are interpolated to form a closed curve. This input is terminated with *END.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|-------|---|-------|---|-------|---|---|---|---|----|
| Variable | X | | Y | | Z | | | | | |
| Type | E16.0 | | E16.0 | | E16.0 | | | | | |
| Default | none | | none | | none | | | | | |

VARIABLE**DESCRIPTION**

X, Y, Z Location coordinates of a target node.

Remarks:

1. **INTERFACE_BLANKSIZE_DEVELOPMENT.** The keyword file specified on the second data card for the [*INTERFACE_BLANKSIZE_DEVELOPMENT](#) keyword must contain a *DEFINE_TARGET_BOUNDARY keyword.
2. **Example.** A partial keyword input is shown below. Note that the input is in a 3E16.0 FORTRAN format. Also note that the first and last curve points coincide.

```
*KEYWORD
*DEFINE_TARGET_BOUNDARY
-1.83355e+02    -5.94068e+02    -1.58639e+02
-1.80736e+02    -5.94071e+02    -1.58196e+02
-1.78126e+02    -5.94098e+02    -1.57813e+02
-1.75546e+02    -5.94096e+02    -1.57433e+02
-1.72888e+02    -5.94117e+02    -1.57026e+02
      ⋮                ⋮                ⋮
-1.83355e+02    -5.94068e+02    -1.58639e+02
```

```
*END
```

3. **IGES to Keyword Format.** Typically, these boundary nodes are obtained from the boundary curves for a final (trimmed) piece or from a draw blank

edge at a certain distance outside of the draw beads. LS-PrePost 4.1 can generate the points for this keyword from IGES data. To use IGES data select *Curve* → *Convert* → *Method (To Keyword)* → *Select *DEFINE_TARGET_BOUNDARY*; pick the curves; and then select *To Key*. To output in keyword format, choose *File* → *Save as* → *Save Keyword As*, and select “Output Version” as “V971_R7”.

Revisions:

This feature is available in LS-DYNA R6 Revision 74560 and later releases.

***DEFINE_TRACER_PARTICLES_2D**

Purpose: Define tracer particles that follow the deformation of a material. This is useful for visualizing the deformation of a part that is being adapted in a metal forming operation. Nodes used as tracer particles should only be used for visualization and not associated with anything in the model that may alter the response of the model, e.g., they should not be used in any elements except those with null materials.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|---|---|---|---|---|---|
| Variable | NSET | PSET | | | | | | |
| Type | I | I | | | | | | |
| Default | none | 0 | | | | | | |

VARIABLE**DESCRIPTION**

NSET

The node set ID for the nodes used as tracer particles.

PSET

Optional part set ID. If this part set is specified, only tracer particles in these parts are updated and the others are stationary. If this part set is not specified, all tracer particles are updated.

***DEFINE_TRANSFORMATION**

Purpose: Define a transformation for the INCLUDE_TRANSFORM keyword option. The *DEFINE_TRANSFORMATION command must be defined before the *INCLUDE_TRANSFORM command can be used.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|---|---|---|---|---|---|---|
| Variable | TRANID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

Transformation Cards. Include as many cards as necessary. This input ends at the next keyword (“*”) card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

| Variable | OPTION | A1 | A2 | A3 | A4 | A5 | A6 | A7 |
| Type | A | F | F | F | F | F | F | F |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| TRANID | Transform ID. |
| OPTION | For the available options see the table below. |
| A1-A7 | Parameters. See Table 15-56 below for the available options. |

| OPTION | PARAMETERS | FUNCTION |
|--------|----------------------------|---|
| MIRROR | a1, a2, a3, a4, a5, a6, a7 | Reflect, about a mirror plane defined to contain the point (a1, a2, a3) having its normal pointing from point (a1, a2, a3) toward (a4, a5, a6). Setting a7 = 1 reflects the coordinate system as well, i.e., the mirrored coordinate system uses the left-hand-rule to determine the local z-axis. |
| SCALE | a1, a2, a3 | Scale the global x, y, and z coordinates of a point by a1, a2, and a3, respectively. If zero, a default of unity is set. |
| ROTATE | a1, a2, a3, a4, a5, a6, a7 | <p>Rotate through an angle (deg), a7, about a line with direction cosines a1, a2, and a3 passing through the point with coordinates a4, a5, and a6.</p> <p>If a4 through a7 are zero, then a1 and a2 are the ID's of two POINTs and a3 defines the rotation angle. The axis of rotation is defined by a vector going from point with ID a1 to point with ID a2.</p> |
| TRANSL | a1, a2, a3 | Translate the x, y, and z coordinates of a point by a1, a2, and a3, respectively. |
| POINT | a1,a2,a3,a4 | Define a point with ID, a1, with the initial coordinates a2, a3, and a4. |
| POS6P | a1, a2, a3, a4, a5, a6 | Positioning by 6 points. Affine transformation (rotation and translation, no scaling) given by three start points a1, a2, and a3 and three target points a4, a5, and a6. The six POINTs must be defined before they are referenced. Only 1 POS6P option is permitted within a *DEFINE_TRANSFORMATION definition. |
| POS6N | a1, a2, a3, a4, a5, a6 | Positioning by 6 nodes. Affine transformation (rotation and translation, no scaling) given by three start nodes a1, a2, and a3 and three target nodes a4, a5, and a6. The six nodes must be defined before they are referenced. Only 1 POS6N option is permitted within a |

| OPTION | PARAMETERS | FUNCTION |
|--------|------------|------------------------------------|
| | | *DEFINE_TRANSFORMATION definition. |

Table 15-56. List of allowed transformations.

Each option represents a transformation matrix. When more than one option is used, the transformation matrix defined by MIRROR, SCALE, ROTATE or TRANSL is applied to the previously defined existing matrix to form the new global transformation matrix. Therefore the ordering of the SCALE, ROTATE, and TRANSL commands is important. It is generally recommended to first scale, then rotate, and finally translate the model. POS6P and POS6N differ from other options by not applying their transformation matrix to the existing global matrix. Instead the transformation matrix defined by POS6P or POS6N replaces the existing matrix and becomes the new global transformation matrix.

The POINT option in ROTATE provides a means of defining rotations about axes defined by the previous transformations. The coordinates of the two POINTs are transformed by all the transformations up to the transformation where they are referenced. The POINTs must be defined before they are referenced, and their identification numbers are local to each *DEFINE_TRANSFORMATION. The coordinates of a POINT are transformed using all the transformations before it is referenced, not just the transformations between its definition and its reference. To put it another way, while the ordering of the transformations is important, the ordering between the POINTs and the transformations is not important.

NOTE: When *DEFINE_TRANSFORMATION is called from within the target of an *INCLUDE_TRANSFORMATION keyword, the result will involve stacked transformations.

In the following example, the *DEFINE_TRANSFORMATION command is used 3 times to input the same dummy model and position it as follows:

4. Transformation id 1000 imports the dummy model (dummy.k) and rotates it 45 degrees about z-axis at the point (0.0,0.0,0.0). Transformation id 1001 performs the same transformation using the POINT option.
5. Transformation id 2000 imports the same dummy model (dummy.k) and translates 1000 units in the x direction.
6. Transformation id 3000 imports the same dummy model (dummy.k) and translates 2000 units in the x direction. For each *DEFINE_TRANSFORMATION, the commands TRANSL, SCALE, and ROTATE are available. The

transformations are applied in the order in which they are defined in the file, e.g., transformation id 1000 in this example would translate, scale and then rotate the model. *INCLUDE_TRANSFORM uses a transformation id defined by a *DEFINE_TRANSFORMATION command to import a model and perform the associated transformations. It also allows the user upon importing the model to apply offsets to the various entity ids and perform unit conversion of the imported model.

*DEFINE

*DEFINE_TRIM_SEED_POINT_COORDINATES

*DEFINE_TRIM_SEED_POINT_COORDINATES

Purpose: The keyword facilitates blank trimming during a stamping line die simulation. It allows for the trimming process and inputs to be defined independent of the previous process simulation results and is applicable to shell, solid and laminate.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-----|-----|-----|-----|-----|-----|---|
| Variable | NSEED | X1 | Y1 | Z1 | X2 | Y2 | Z2 | |
| Type | I | F | F | F | F | F | F | |
| Default | none | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | |

VARIABLE

DESCRIPTION

| | |
|------------|---|
| NSEED | Number of seed points. Maximum value of "2" is allowed. |
| X1, Y1, Z1 | Location coordinates of seed point 1. |
| X2, Y2, Z2 | Location coordinates of seed point 2. |

Remarks:

- Associated Keywords.** This keyword is used in conjunction with keywords *ELEMENT_TRIM and *DEFINE_CURVE_TRIM, where variables NSEED1 and NSEED2 should be left as blank. For detailed usage, refer to **Seed Node Definition** section in *DEFINE_CURVE_TRIM.
- Number of Seed Points.** Variable NSEED is set to the number of seed points desired. For example, in a double attached drawn panel trimming, NSEED would equal to 2.
- Example Input Deck.** A partial keyword inputs for a single drawn panel trimming is listed below.

```
*INCLUDE_TRIM
drawn.dynain
*ELEMENT_TRIM          1
*DEFINE_CURVE_TRIM_NEW

*DEFINE_VECTOR
```

11,0.0,0.0,0.0,0.0,0.0,0.0,10.0

Typically, seed point coordinates can be selected from the stationary post in punch home position.

4. **Revision Information.** This feature is available in LS-DYNA R4 Revision 53048 and later releases.

***DEFINE_VECTOR**

Purpose: Define a vector by defining the coordinates of two points.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-----|-----|-----|--------|
| Variable | VID | XT | YT | ZT | XH | YH | ZH | CID |
| Type | I | F | F | F | F | F | F | I |
| Default | 0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | global |

VARIABLE**DESCRIPTION**

| | |
|-----|---|
| VID | Vector ID |
| XT | X-coordinate of tail of vector |
| YT | Y-coordinate of tail of vector |
| ZT | Z-coordinate of tail of vector |
| XH | X-coordinate of head of vector |
| YH | Y-coordinate of head of vector |
| ZH | Z-coordinate of head of vector |
| CID | Coordinate system ID to define vector in local coordinate system. All coordinates, XT, YT, ZT, XH, YH, and ZH are in respect to CID. EQ.0: global (default). |

Remarks:

1. **Numerical Inaccuracies.** The coordinates should differ by a certain margin to avoid numerical inaccuracies.

DEFINE_VECTOR_NODES**DEFINE*****DEFINE_VECTOR_NODES**

Purpose: Define a vector with two nodal points.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

VARIABLE**DESCRIPTION**

| | |
|-------|--------------------------------------|
| VID | Vector ID |
| NODET | Nodal point to define tail of vector |
| NODEH | Nodal point to define head of vector |

*DEFORMABLE_TO_RIGID

The cards in this section are defined in alphabetical order and are as follows:

*DEFORMABLE_TO_RIGID

*DEFORMABLE_TO_RIGID_AUTOMATIC

*DEFORMABLE_TO_RIGID_INERTIA

If one of these cards is defined, then any deformable part defined in the model may be switched to rigid during the calculation. Parts that are defined as rigid (*MAT_RIGID) in the input are permanently rigid and cannot be changed to deformable.

Deformable parts may be switched to rigid at the start of the calculation by specifying them on the *DEFORMABLE_TO_RIGID card.

Part switching may be specified on a restart (see RESTART section of this manual) or it may be performed automatically by use of the *DEFORMABLE_TO_RIGID_AUTOMATIC cards.

The *DEFORMABLE_TO_RIGID_INERTIA cards allow inertial properties to be defined for deformable parts that are to be swapped to rigid at a later stage.

It is not possible to perform part material switching on a restart if it was not flagged in the initial analysis. The reason for this is that extra memory needs to be set up internally to allow the switching to take place. If part switching is to take place on a restart, but no parts are to be switched at the start of the calculation, no inertia properties for switching and no automatic switching sets are to be defined, then just define one *DEFORMABLE_TO_RIGID card without further input.

*DEFORMABLE_TO_RIGID

*DEFORMABLE_TO_RIGID

*DEFORMABLE_TO_RIGID

Purpose: Define materials to be switched to rigid at the start of the calculation.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|-------|---|---|---|---|---|
| Variable | PID | MRB | PTYPE | | | | | |
| Type | I | I | A | | | | | |
| Default | none | 0 | | | | | | |

VARIABLE

DESCRIPTION

PID Part ID of the part which is switched to a rigid material, also see *PART.

MRB Part ID of the master rigid body to which the part is merged. If zero, the part becomes either an independent or master rigid body.

PTYPE Type of PID:
EQ. "PART": PID is a part ID.
EQ. "PSET": PID is a part set ID. All parts included in part set PID will be switched to rigid at the start of the calculation.

***DEFORMABLE_TO_RIGID_AUTOMATIC**

Purpose: Define a set of parts to be switched to rigid or to deformable at some stage during the calculation.

Card Summary:

Card 1. This card is required

| Default | 0 | 0 | 0 | 0. | 0 | 0 | 0 | |

VARIABLE**DESCRIPTION**

| | |
|-------|---|
| SWSET | Set number for this automatic switch set. Must be unique. |
| CODE | <p>Activation switch code. Defines the test to activate the automatic material switch of the part:</p> <p>EQ.0: switch takes place at time 1,</p> <p>EQ.1: switch takes place between time 1 and time 2 if rigid wall force (specified below) is zero,</p> <p>EQ.2: switch takes place between time 1 and time 2 if contact surface force (specified below) is zero,</p> <p>EQ.3: switch takes place between time 1 and time 2 if rigid wall force (specified below) is non-zero,</p> <p>EQ.4: switch takes place between time 1 and time 2 if contact surface force (specified below) is non-zero.</p> <p>EQ.5: switch is controlled by *SENSOR_CONTROL with TYPE = DEF2RIG; see *SENSOR_CONTROL. When CODE = 5, inputs of column 3 to column 8, TIME1 to PAIRED, are ignored.</p> |
| TIME1 | Switch will not take place before this time. |
| TIME2 | <p>Switch will not take place after this time:</p> <p>EQ.0: Time 2 set to 10^{20}</p> |
| TIME3 | Delay period. After this part switch has taken place, another automatic switch will not take place for the duration of the delay period. If set to zero, a part switch may take place immediately after this switch. |
| ENTNO | Rigid wall / contact surface number for switch codes 1, 2, 3, 4. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| RELSW | <p>Related switch set. The related switch set is another automatic switch set that must be activated before this part switch can take place:</p> <p>EQ.0: no related switch set.</p> |
| PAIRED | <p>Define a pair of related switches.</p> <p>EQ.0: not paired</p> <p>EQ.1: paired with switch set RELSW and is the Master switch.</p> <p>EQ.-1: paired with switch set RELSW and is the Slave switch.</p> |
| NRBF | <p>Nodal rigid body flag.</p> <p>For all values of NRBF, nodal rigid bodies defined using *CONSTRAINED_NODAL_RIGID_BODY and *CONSTRAINED_GENERALIZED_WELD_OPTION, which share any nodes with a rigid body created by deformable-to-rigid switching, are merged with the latter to form a single rigid body. Other actions dependent upon the value of NRBF are:</p> <p>EQ.0: no further action,</p> <p>EQ.1: delete all remaining nodal rigid bodies, that is, delete those nodal rigid bodies that do not share any nodes with a rigid body created by deformable-to-rigid switching,</p> <p>EQ.2: Activate nodal rigid bodies.</p> |
| NCSF | <p>Nodal constraint set flag.</p> <p>If nodal constraint / spot weld definitions are active in the deformable bodies that are switched to rigid, then the definitions should be deleted to avoid instabilities:</p> <p>EQ.0: no change,</p> <p>EQ.1: delete,</p> <p>EQ.2: activate.</p> |
| RWF | <p>Flag to delete or activate rigid walls:</p> <p>EQ.0: no change,</p> <p>EQ.1: delete,</p> <p>EQ.2: activate.</p> |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| DTMAX | Maximum permitted time step size after switch. |
| D2R | Number of deformable parts to be switched to rigid plus number of rigid parts for which new master/slave rigid body combinations will be defined: EQ.0: no parts defined. |
| R2D | Number of rigid parts to be switched to deformable: EQ.0: no parts defined. |
| OFFSET | Optional contact thickness for switch to deformable. For contact, its value should be set to a value greater than the contact thickness offsets to ensure the switching occurs prior to impact. This option applies if and only if CODE is set to 3 or 4. For CODE = 3 all rigid wall options are implemented. For CODE = 4, the implementation works for the contact type CONTACT_AUTOMATIC when the options: ONE_WAY_SURFACE_TO_SURFACE, NODES_TO_SURFACE, and SURFACE_TO_SURFACE are invoked. |

Deformable to Rigid Cards. D2R additional cards with one for each part.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|-------|---|---|---|---|---|
| Variable | PID | MRB | PTYPE | | | | | |
| Type | I | I | A | | | | | |
| Default | none | 0 | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| PID | Part ID of the part which is switched to a rigid material. When PID is merged to another rigid body by the MRB field, this part is allowed to be rigid before the switch. |
| MRB | Part ID of the master rigid body to which part PID is merged. If zero, part PID becomes either an independent or master rigid body. |

| VARIABLE | DESCRIPTION |
|----------|--|
| PTYPE | Type of PID: EQ.PART: PID is a part ID. EQ.PSET: PID is a part set ID. |

Rigid to Deformable Cards. R2D additional cards with one for each part.

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|---|---|---|---|---|---|
| Variable | PID | PTYPE | | | | | | |
| Type | I | A | | | | | | |
| Default | none | | | | | | | |

| VARIABLE | DESCRIPTION |
|----------|--|
| PID | Part ID of the part which is switched to a deformable material. |
| PTYPE | Type of PID: EQ.PART: PID is a part ID. EQ.PSET: PID is a part set ID. |

Remarks:

- Allowed Contact Types.** Only surface to surface and node to surface contacts can be used to activate an automatic part switch.
- Rigid Wall Numbering.** Rigid wall numbers are the order in which they are defined in the deck. The first rigid wall and the first contact surface encountered in the input deck will have an entity number of 1. The contact surface ID is that as defined on the *CONTACT_..._ID card.
- Paired Switches.** Switch sets may be paired together to allow a pair of switches to be activated more than once. Each pair of switches should use consistent values for CODE, i.e. 1 & 3 or 2 & 4. Within each pair of switches, the related switch, RELSW, should be set to the ID of the other switch in the pair. The Master switch (PAIRED = 1) will be activated before the Slave switch (PAIRED = -1). Pairing allows the multiple switches to take place as for example when contact is made and lost several times during an analysis.

If the delete switch is activated, *all* corresponding constraints are deactivated regardless of their relationship to a switched part. By default, constraints which are directly associated with a switched part are deactivated/activated as necessary.

\$ Define a pair or related switches that will be activated by (no)force on
\$ Contact 3. To start with switch set 20 will be activated (PAIRED=1) swapping
\$ the PARTS to RIGID. When the contact force is none zero switch set 10 will be
\$ activated swapping the PARTS to DEFORMABLE. If the contact force returns to
\$ zero switch set 20 will be activated again making the PARTS RIGID.

DEFORMABLE_TO_RIGID_INERTIA**DEFORMABLE_TO_RIGID*****DEFORMABLE_TO_RIGID_INERTIA**

Purpose: Inertial properties can be defined for the new rigid bodies that are created when the deformable parts are switched. These can only be defined in the initial input if they are needed in a later restart. Unless these properties are defined, LS-DYNA will recompute the new rigid body properties from the finite element mesh. The latter requires an accurate mesh description. *When rigid bodies are merged to a master rigid body, the inertial properties defined for the master rigid body apply to all members of the merged set.*

VARIABLE

DESCRIPTION

PSID

Part set ID. See *SET_PART.

Revisions:

This feature is available in LS-DYNA R5 Revision 59165 or later releases.

***ELEMENT_BEAM_{OPTION}_{OPTION}**

Available options include:

<BLANK>

THICKNESS, SCALAR, SCALR or SECTION

PID

OFFSET

ORIENTATION

WARPAGE

ELBOW (*beta*)

Purpose: Define two node elements including 3D beams, trusses, 2D axisymmetric shells, and 2D plane strain beam elements. The type of the element and its formulation is specified through the part ID (see *PART) and the section ID (see *SECTION_BEAM).

Two alternative methods are available for defining the cross sectional property data. The THICKNESS and SECTION options are provided for the user to override the *SECTION_BEAM data which is taken as the default if the THICKNESS or SECTION option is not used. The SECTION option applies only to resultant beams (ELFORM = 2 on *SECTION_BEAM). End release conditions are imposed using constraint equations, and caution must be used with this option as discussed in [Remark 2](#).

The SCALAR and SCALR options apply only to material model type 146, *MAT_1D-OF_GENERALIZED_SPRING.

The PID option is used by the type 9 spot weld element only and is ignored for all other beam types. When the PID option is active, an additional card is read that gives two part ID's that are tied by the spot weld element. If the PID option is inactive for the type 9 element, the nodal points of the spot weld are located to the two nearest master segments. In either case, *CONTACT_SPOTWELD must be defined with the spot weld beam part as slave and the shell parts (including parts PID1 and PID2) as master. The surface of each segment should project to the other and in the most typical case the node defining the weld, assuming only one node is used, should lie in the middle; however, this is not a requirement. Note that with the spot weld elements only one node is needed to define the weld, and two nodes are optional.

The OFFSET option is not available for discrete beam elements. Neither the OFFSET option nor the OREINTATION option is available for truss elements, spotweld beam elements, or the 2D beam element forms 7 or 8.

The ELBOW option is a 3-node beam element with quadratic interpolation that is tailored for the piping industry. It includes 12 degrees of freedom, including 6 ovalization degrees of freedom for describing the ovalization, per node. That is a total of 36 DOFs for each element. An internal pressure can also be given that tries to stiffen the pipe. The pressure, if activated accordingly, can also contribute to the elongation of the pipe. The control node must be given, but it is only used for initially straight elbow elements. For curved elements the curvature center is used as the control node. See *SECTION_BEAM for more information about the physical properties such as pressure and output options.

VARIABLE**DESCRIPTION**

EID

Element ID. A unique ID is generally required, that is, EID must be different from the element ID's also defined under *ELEMENT_DISCRETE and *ELEMENT_SEATBELT. If the field, BEAM, is set to 1 on the keyword input for *DATABASE_BINARY_D3PLOT, the null beams used for visualization are not created for the latter two types, and the ID's used for the discrete elements and the seatbelt elements can be identical to those defined here.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| PID | Part ID, see *PART. |
| N1 | Nodal point (end) 1. |
| N2 | Nodal point (end) 2. This node is optional for the spot weld, beam type 9, since if it not defined it will be created automatically and given a non-conflicting nodal point ID. Nodes N1 and N2 are automatically positioned for the spot weld beam element. For the zero length discrete beam elements where one end is attached to ground, set $N2 = -N1$. For this case, a fully constrained nodal point will be created with a unique ID for node N2. |
| N3 | Nodal point 3 for orientation. The third node, N3, is optional for beam types 3, 6, 7, 8, and, if the cross-section is circular, beam types 1 and 9. The third node is used for the discrete beam, type 6, if and only if SCOOR is set to 2.0 in the *SECTION_BEAM input, but even in this case it is optional. An orientation vector can be defined directly by using the option, ORIENTATION. For this case N3 can be defined as zero. |
| RT1, RT2 | <p>Release conditions for translations at nodes N1 and N2, respectively:</p> <p>EQ.0: no translational degrees-of-freedom are released</p> <p>EQ.1: x-translational degree-of-freedom</p> <p>EQ.2: y-translational degree-of-freedom</p> <p>EQ.3: z-translational degree-of-freedom</p> <p>EQ.4: x and y-translational degrees-of-freedom</p> <p>EQ.5: y and z-translational degrees-of-freedom</p> <p>EQ.6: z and x-translational degrees-of-freedom</p> <p>EQ.7: x, y, and z-translational degrees-of-freedom (3DOF)</p> <p>This option does not apply to the spot weld, beam type 9.</p> |
| RR1, RR2 | <p>Release conditions for rotations at nodes N1 and N2, respectively:</p> <p>EQ.0: no rotational degrees-of-freedom are released</p> <p>EQ.1: x-rotational degree-of-freedom</p> <p>EQ.2: y-rotational degree-of-freedom</p> <p>EQ.3: z-rotational degree-of-freedom</p> <p>EQ.4: x and y-rotational degrees-of-freedom</p> |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | EQ.5: y and z -rotational degrees-of-freedom EQ.6: z and x -rotational degrees-of-freedom EQ.7: x , y , and z -rotational degrees-of-freedom (3DOF) This option does not apply to the spot weld, beam type 9. |
| LOCAL | Coordinate system option for release conditions: EQ.1: global coordinate system EQ.2: local coordinate system (default) |
| PARM1 | Based on beam type: Type.EQ.1: beam thickness, s -direction at node 1 Type.EQ.2: area Type.EQ.3: area Type.EQ.4: beam thickness, s -direction at node 1 Type.EQ.5: beam thickness, s -direction at node 1 Type.EQ.6: volume, see description for VOL below. Type.EQ.7: beam thickness, s -direction at node 1 Type.EQ.8: beam thickness, s -direction at node 1 Type.EQ.9: beam thickness, s -direction at node 1 |
| PARM2 | Based on beam type: Type.EQ.1: beam thickness, s -direction at node 2 Type.EQ.2: I_{ss} Type.EQ.3: ramp-up time for dynamic relaxation Type.EQ.4: beam thickness, s -direction at node 2 Type.EQ.5: beam thickness, s -direction at node 2 Type.EQ.6: Inertia, see description for INER below. Type.EQ.7: beam thickness, s -direction at node 2 Type.EQ.8: beam thickness, s -direction at node 2 Type.EQ.9: beam thickness, s -direction at node 2 |
| PARM3 | Based on beam type: Type.EQ.1: beam thickness, t -direction at node 1 |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | print. |
| STYPE | Section type (A format) of resultant beam, see Figure 37-1 : EQ.SECTION_01: I-Shape EQ.SECTION_12: Cross EQ.SECTION_02: Channel EQ.SECTION_13: H-Shape EQ.SECTION_03: L-Shape EQ.SECTION_14: T-Shape 2 EQ.SECTION_04: T-Shape EQ.SECTION_15: I-Shape 3 EQ.SECTION_05: Tubular box EQ.SECTION_16: Channel 2 EQ.SECTION_06:Z-Sape EQ.SECTION_17: Channel 3 EQ.SECTION_07: Trapezoidal EQ.SECTION_18: T-Shape 3 EQ.SECTION_08: Circular EQ.SECTION_19: Box-Shape 2 EQ.SECTION_09: Tubular EQ.SECTION_20: Hexagon EQ.SECTION_10: I-Shape 2 EQ.SECTION_21: Hat-Shape EQ.SECTION_11: Solid box EQ.SECTION_22: Hat-Shape 2 |
| D1-D6 | Input parameters for section option using STYPE above. |
| PID1 | Optional part ID for spot weld element type 9. |
| PID2 | Optional part ID for spot weld element type 9. |
| VOL | Volume of discrete beam and scalar (MAT_146) beam. If the mass density of the material model for the discrete beam is set to unity, the magnitude of the lumped mass can be defined here instead. This lumped mass is partitioned to the two nodes of the beam element. The translational time step size for the type 6 beam is dependent on the volume, mass density, and the translational stiffness values, so it is important to define this parameter. Defining the volume is also essential for mass scaling if the type 6 beam controls the time step size. |
| INER | Mass moment of inertia for the six degree of freedom discrete beam and scalar (MAT_146) beam. This lumped inertia is partitioned to the two nodes of the beam element. The rotational time step size for the type 6 beam is dependent on the lumped inertia and the rotational stiffness values, so it is important to define this parameter if the rotational springs are active. Defining the rotational inertia is also essential for mass scaling if the type 6 beam rotational stiffness controls the time step size. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| CID | Coordinate system ID for orientation, material type 146; see *DEFINE_COORDINATE_SYSTEM. If CID = 0, a default coordinate system is defined in the global system. |
| DOFN1 | Active degree-of-freedom at node 1, a number between 1 to 6 where 1, 2, and 3 are the x , y , and z -translations and 4, 5, and 6 are the x , y , and z -rotations. This degree-of-freedom acts in the local system given by CID above. This input applies to material model type 146. |
| DOFN2 | Active degree-of-freedom at node 2, a number between 1 to 6 as described in DOFN1 above. This degree-of-freedom acts in the local system given by CID above. This input applies to material model type 146. |
| CID1 | Coordinate system ID at node 1 for orientation for material type 146; see *DEFINE_COORDINATE_SYSTEM. If CID1 = 0, a default coordinate system is defined in the global system. |
| CID2 | Coordinate system ID at node 2 for orientation for material type 146; see *DEFINE_COORDINATE_SYSTEM. If CID2 = 0, a default coordinate system is defined in the global system. |
| DOFNS | Active degrees-of-freedom at node 1 and node 2. A two-digit number, the first for node 1 and the second for node 2, between 11 and 66 is expected where 1, 2, and 3 are the x , y , and z -translations and 4, 5, and 6 are the x , y , and z -rotations. These degrees-of-freedom acts in the local system given by CID1 and CID2 above. This input applies to material model type 146. For example, if DOFNS = 12, node 1 has an x -translation and node 2 has a y -translation. |
| WX1-WZ1 | Offset vector at nodal point N1. See Remark 7 . |
| WX2-WZ2 | Offset vector at nodal point N2. See Remark 7 . |
| VX,VY,VZ | Coordinates of an orientation vector relative to node N1. In this case, the orientation vector points to a virtual third node, so the field N3 should be left undefined. |
| SN1 | Scalar nodal point (end) 1. This node is required for the WARPAGE option. |
| SN2 | Scalar nodal point (end) 2. This node is required for the WARPAGE option. |

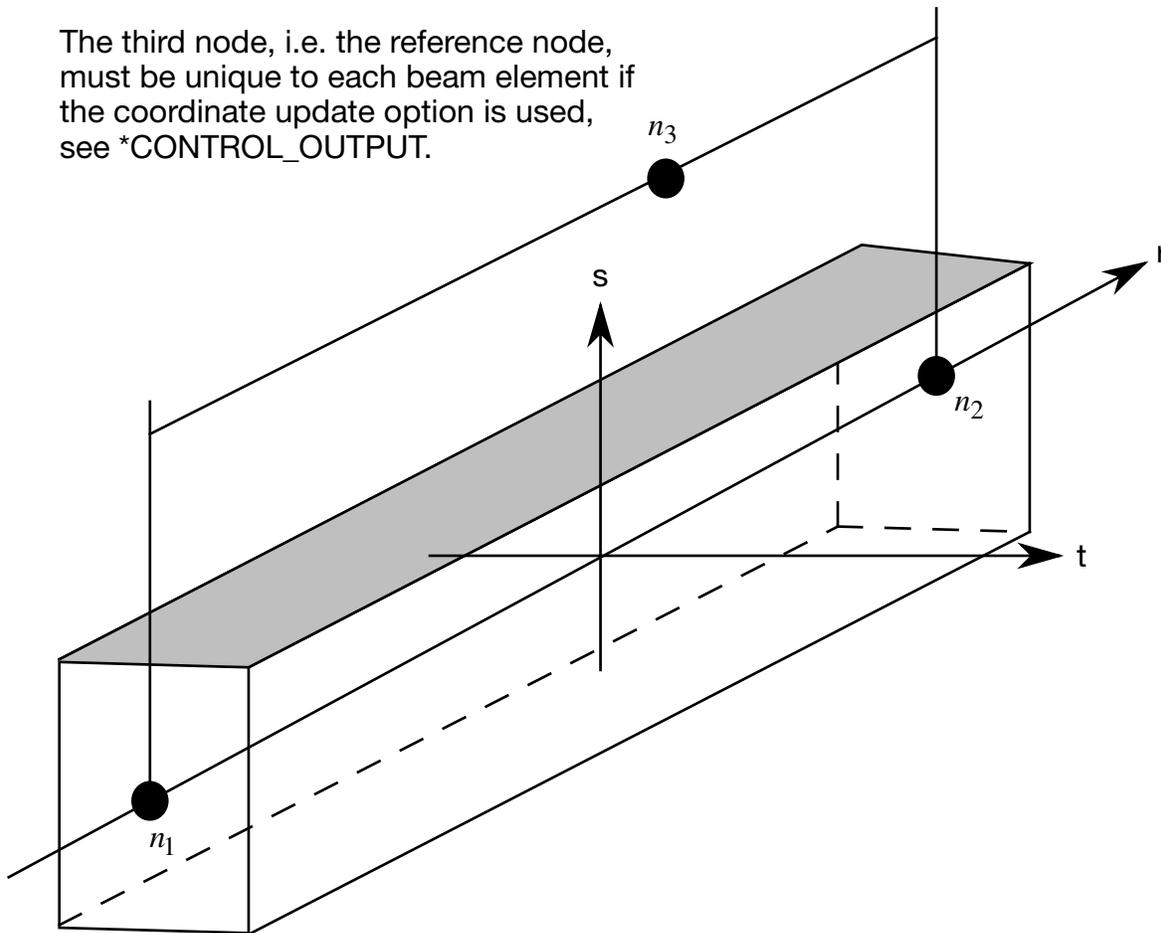

Figure 17-1. LS-DYNA beam elements. Node n_3 determines the initial orientation of the cross section.

| VARIABLE | DESCRIPTION |
|----------|---|
| MN | Middle node for the ELBOW element. See Remark 8 . |

Remarks:

1. **Beam Orientation.** A plane through N_1 , N_2 , and N_3 defines the orientation of the principal r - s plane of the beam; see [Figure 17-1](#).
2. **Release Conditions.** The option to specify release conditions applies to all three-dimensional beam elements. The released degrees-of-freedom can be either global, or local relative to the local beam coordinate system as shown in [Figure 17-1](#). A local coordinate system is stored for each node of the beam element and the orientation of the local coordinate systems rotates with the node. To properly track the response, the nodal points with a released resultant are automatically replaced with new nodes to accommodate the added

degrees-of-freedom. Then constraint equations are used to join the nodal points together with the proper release conditions imposed.

Nodal points which belong to beam elements that have release conditions applied cannot be subjected to other constraints, such as applied displacement/velocity/acceleration boundary conditions, nodal rigid bodies, nodal constraint sets, or any of the constraint type contact definitions.

Force type loading conditions and penalty based contact algorithms may be used with this option.

Please note that specification of translational release conditions may lead to nonphysical constraints, but this should not be a problem if the displacements are infinitesimal.

3. **Beam Properties.** If the THICKNESS option is not used, or if THICKNESS is used but essential PARMx values are not provided, beam properties are taken from *SECTION_BEAM.
4. **Discrete Beam Elements.** In the case of the THICKNESS option for type 6, discrete beam elements, PARM1 through PARM5 replace the first five fields on Card 2 of *SECTION_BEAM. Cables are a subset of type 6 beams. PARM1 is for non-cable discrete beams and is optional for cables, PARM2 and PARM3 apply only to non-cable discrete beams, and PARM4 and PARM5 apply only to cables.
5. **PARM5.** In the THICKNESS option, PARM5 applies only to beam types 2, 6 (cables only), and 9.
6. **Stress Resultants.** The stress resultants are output in local coordinate system for the beam. Stress information is optional and is also output in the local system for the beam.
7. **Offsets.** Beam offsets are sometimes necessary for correctly modeling beams that act compositely with other elements such as shells or other beams. When the OFFSET option is specified, global X, Y, and Z components of two offset vectors are given, one vector for each of the two beam nodes. The offset vector extends from the beam node (N1 or N2) to the reference axis of the beam. The beam reference axis lies at the origin of the local *s* and *t*-axes. For beam formulations 1 and 11, this origin is halfway between the outermost surfaces of the beam cross-section. Note that for cross-sections that are not doubly symmetric, such as a T-section, the reference axis does not pass through the centroid of the cross-section. For beam formulation 2, the origin is at the centroid of the cross-section.

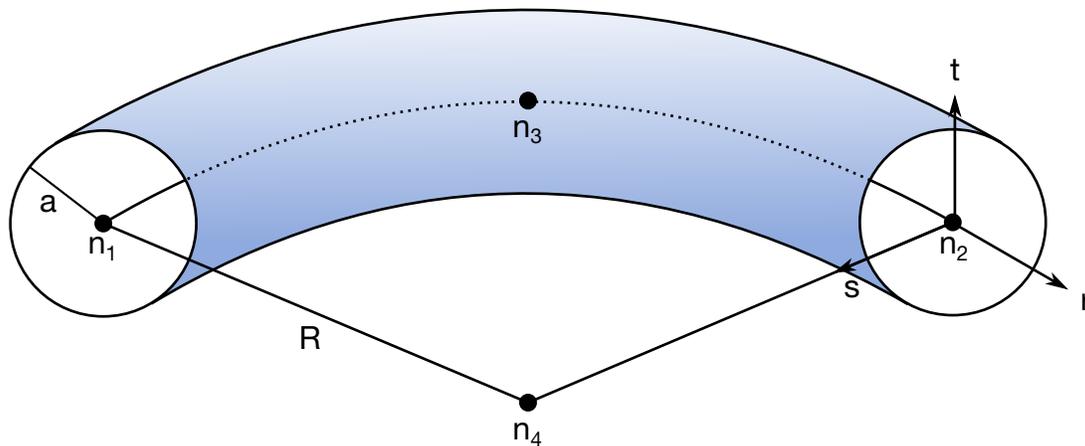

Figure 17-2. LS-DYNA Elbow element. Node n_4 is the control node and is given as the beam center of curvature.

8. **Elbow.** The Elbow beam is defined with 4 nodes; see [Figure 17-2](#). Nodes n_1 and n_2 are the end nodes, and node n_3 is the middle node. It is custom to set n_3 at the midpoint of the beam. Node n_4 is an orientation node that should be at the curvature center of the beam. If a straight beam is defined initially, the orientation node must be defined and should be on the convex side of the beam. If a curved beam is defined initially, the orientation node is automatically calculated as the center of the beam curvature. However, an orientation node is still required at the input.

The extra nodes that include the ovalization degree of freedom are written to the message file during initialization. These extra nodes have 3 DOFs each. That means that there are 2 extra nodes for each physical node. For example, it can look something like this:

```
ELBOW BEAM:           1
n1-n3-n2:             1     3     2
ovalization nodes:    5     7     6
                     8     10    9
```

And it means that node 1 has the ovalization extra nodes 5 and 8. The first line of ovalization nodes includes the c_1 , c_2 and c_3 parameters, and the second line includes the d_1 , d_2 and d_3 parameters. That means that node 5 includes c_1 , c_2 and c_3 , and node 8 includes d_1 , d_2 and d_3 for beam node 1. All ovalization dofs can be written to the ASCII file "elbowov" if the correct print flag IOVPR is set to 1 on *SECTION_BEAM. These extra nodes can be constrained as usual nodes. For example, for a cantilever beam that is mounted at node 1, the nodes 1, 5 and 8 should be constrained. The ovalization is approximated with the following trigonometric function:

$$w(r, \theta) = \sum_{k=1}^3 \sum_{m=1}^3 h_k(r) (c_m^k \cos 2m\theta + d_m^k \sin 2m\theta), \quad -1 \leq r \leq 1, 0 \leq \theta < 2\pi$$

where h_k is the interpolation function at the physical node k .

The Elbow beam only supports tubular cross sections and the pipe outer radius, a , should be smaller than the pipe bend radius, R . That is $a/R \ll 1$. Moreover, the ELBOW beams have 4 stresses: axial rr -, shear rs -, shear rt - and loop-stresses. The loop stress is written at each integration point and can be visualized in LS-PrePost with the user fringe plot file "elbwlp.k". NOTE that the loop-stress is not written to d3plot as default! The NEIPB flag on *DATABASE_EXTENT_BINARY must be set to enable d3plot support.

Right now there is only basic support from the material library. The following materials are currently supported for the ELBOW beam (if requested more materials might be added in the future):

- *MAT_ELASTIC (MAT_001)
- *MAT_PLASTIC_KINEMATIC (MAT_003)
- *MAT_ELASTIC_PLASTIC_THERMAL (MAT_004)
- *MAT_VISCOELASTIC (MAT_006)
- *MAT_PIECEWISE_LINEAR_PLASTICITY (MAT_024)
- *MAT_DAMAGE_3 (MAT_153, explicit only)
- *MAT_CONCRETE_BEAM (MAT_195)

***ELEMENT_BEAM_PULLEY**

Purpose: Define pulley for beam elements. This feature is implemented for truss beam elements (*SECTION_BEAM, ELFORM = 3) using materials *MAT_001 and *MAT_156 or discrete beam elements (ELFORM = 6) using *MAT_CABLE_DISCRETE_BEAM.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|-----|-----|------|-----|
| Variable | PUID | BID1 | BID2 | PNID | FD | FS | LMIN | DC |
| Type | I | I | I | I | F | F | F | F |
| Default | none | 0 | 0 | 0 | 0.0 | 0.0 | 0.0 | 0.0 |

VARIABLE**DESCRIPTION**

| | |
|------|---|
| PUID | Pulley ID. A unique number has to be used. |
| BID1 | Truss beam element 1 ID. |
| BID2 | Truss beam element 2 ID. |
| PNID | Pulley node, NID. |
| FD | Coulomb dynamic friction coefficient. |
| FS | Optional Coulomb static friction coefficient. |
| LMIN | Minimum length, see notes below. |
| DC | Optional decay constant to allow smooth transition between the static and dynamic friction coefficient, i.e., |

$$\mu_c = FD + (FS - FD)e^{-DC \times |v_{rel}|}$$

Remarks:

Elements 1 and 2 should share a node which is coincident with the pulley node. The pulley node should not be on any beam elements.

Pulleys allow continuous sliding of a truss beam element through a sharp change of angle. Two elements (1 & 2 in [Figure 17-22](#) of *ELEMENT_SEATBELT_SLIPRING) meet at the pulley. Node B in the beam material remains attached to the pulley node, but beam material (in the form of unstretched length) is passed from element 1 to

element 2 to achieve slip. The amount of slip at each time step is calculated from the ratio of forces in elements 1 and 2. The ratio of forces is determined by the relative angle between elements 1 and 2 and the coefficient of friction, FD. The tension in the beams are taken as T_1 and T_2 , where T_2 is on the high tension side and T_1 is the force on the low tension side. Thus, if T_2 is sufficiently close to T_1 , no slip occurs; otherwise, slip is just sufficient to reduce the ratio T_2/T_1 to $e^{FC \times \theta}$, where θ is the wrap angle; see [Figures 17-23](#) of *ELEMENT_SEATBELT_SLIPRING. The out-of-balance force at node *B* is reacted on the pulley node; the motion of node *B* follows that of pulley node.

If, due to slip through the pulley, the unstretched length of an element becomes less than the minimum length LMIN, the beam is remeshed locally: the short element passes through the pulley and reappears on the other side (see [Figure 17-22](#)). The new unstretched length of e_1 is $1.1 \times$ minimum length. The force and strain in e_2 and e_3 are unchanged; while the force and strain in e_1 are now equal to those in e_2 . Subsequent slip will pass material from e_3 to e_1 . This process can continue with several elements passing in turn through the pulley.

To define a pulley, the user identifies the two beam elements which meet at the pulley, the friction coefficient, and the pulley node. If BID1 and BID2 are defined as 0 (zero), adjacent beam elements are automatically detected. The two elements must have a common node coincident with the pulley node. No attempt should be made to restrain or constrain the common node for its motion will automatically be constrained to follow the pulley node. Typically, the pulley node is part of a structure and, therefore, beam elements should not be connected to this node directly, but any other feature can be attached, including rigid bodies.

*DATABASE_PLYOUT can be used to write a time history output database plyout for the pulley which records beam IDs, slip, slip rate, resultant force, and wrap angle.

***ELEMENT_BEAM_SOURCE**

Purpose: Define a nodal source for beam elements. This feature is implemented *only* for truss beam elements (*SECTION_BEAM, ELFORM = 3) with material *MAT_001 or for discrete beam elements (ELFORM = 6) with material *MAT_071.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|-------|------|------|-------|------|---|
| Variable | BSID | BSNID | BSEID | NELE | LFED | FPULL | LMIN | |
| Type | I | I | I | I | F | F | F | |
| Default | none | none | none | 0 | 0.0 | 0.0 | 0.0 | |

VARIABLE**DESCRIPTION**

| | |
|-------|---|
| BSID | Beam Source ID. A unique number has to be used. |
| BSNID | Source node ID. |
| BSEID | Source element ID. |
| NELE | Number of elements to be pulled out. |
| LFED | Beam element fed length (typical element initial length). |
| FPULL | Pull-out force. GT.0: Constant value, LT.0: Load curve ID = FPULL which defines pull-out force as a function of time. Either *DEFINE_FUNCTION or *DEFINE_CURVE_FUNCTION (with argument TIME) can be used. |
| LMIN | Minimum beam element length, see notes below. One to two tenth of the fed length LFED is usually a good choice. |

Remarks:

The source node BSNID can be defined by itself or it can be part of another structure. It is free to move in space during the simulation process. Initially, the source node should have the same coordinates as one of the source element (BSEID) nodes, but not having the same ID. If the pre-defined pull-out force FPULL is exceeded in the element next to

the source, beam material gets drawn out by increasing the length of the beam without increasing its axial force (equivalent to ideal plastic flow at a given yield force). If more than the pre-defined length LFED is drawn out, a new beam element is generated. A new beam element has an initial undeformed length of $1.1 \times \text{LMIN}$. The maximum number of elements, NELE, times the fed length, LFED, defines the maximum cable length that can be pulled out from the source node.

*ELEMENT_BEARING_OPTION

The available option is:

TITLE

Purpose: Define a bearing between two nodes. A description of this model can be found in Carney, Howard, Miller, and Benson [2014].

VARIABLE**DESCRIPTION**

| | |
|-------|---|
| ID | Bearing ID. |
| ITYPE | Bearing type: EQ.1: ball bearing EQ.2: roller bearing |
| N1 | Node on centerline of shaft (the shaft rotates). |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| CID1 | Coordinate ID on shaft. The local z-axis defines the axis of rotation. |
| N2 | Node on centerline of bearing (the bearing does not rotate). It should initially coincide with N1. |
| CID2 | Coordinate ID on bearing. The local z-axis defines the axis of rotation. |
| NB | Number of balls or rollers. |
| EBALL | Young's modulus for balls or rollers. |
| PRBALL | Poisson's ratio for balls or rollers. |
| ERACE | Young's modulus for races. |
| PRRACE | Poisson's ratio for races. |
| STRESL | Specified value of the bearing stress required to print a warning message that the value has been reached. If it is 0.0, then no message is printed. |
| D | Diameter of balls or rollers. |
| DI | Bore inner diameter. |
| DO | Bore outer diameter. |
| DM | Pitch diameter. If DM is not specified, it is calculated as the average of DI and DO. |
| A0 | Initial contact angle in degrees |
| BI | Inner groove radius to ball diameter ratio for ball bearings and the roller length for roller bearings.. |
| BO | Outer race groove radius to ball diameter ratio. Unused for roller bearings. |
| PD | Total radial clearance between the ball bearings and races when no load is applied. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| IPFLAG | Preload flag EQ.0: no preload. EQ.1: displacement preload specified. EQ.2: force preload specified. |
| XTRAN | Displacement or force preload in the local x -direction. |
| YTRAN | Displacement or force preload in the local y -direction. |
| ZTRAN | Displacement or force preload in the local z -direction. |
| XROT | Angle (in radians) or moment preload in local x -direction. |
| YROT | Angle (in radians) or moment preload in local y -direction. |

Remarks:

1. **Exceeding Stress Limit Parameter.** If the bearing stress limit parameter, STRESL, is exceeded, a message is written to the messag and d3hsp files. When this value is exceeded, there is no change in element behaviors.
2. **Simulation Precision.** Use of double precision for solution stability is strongly suggested.
3. **Bearing Damping.** A realistic level of bearing damping (which can be included using *ELEMENT_DISCRETE and *MAT_DAMPER_VISCOUS) may be needed for solution stability.
4. **Bearing Forces.** Bearing forces can be output in the brngout file, using *DATABASE_BEARING.

***ELEMENT_DIRECT_MATRIX_INPUT_{OPTION}**

Available options include:

<BLANK>

BINARY

Purpose: Define an element consisting of mass, damping, stiffness, and inertia matrices in a specified file which follows the format used in the direct matrix input, DMIG, of NASTRAN. The supported format is the type 6 symmetric matrix in real double precision. LS-DYNA supports both the standard and the extended precision formats. The binary format from *CONTROL_IMPLICIT_MODES or *CONTROL_IMPLICIT_STATIC_CONDENSATION is another input option. The mass and stiffness matrices are required. The inertia matrix is required when using *LOAD_BODY_OPTION to correctly compute the action of a prescribed base acceleration on the superelement, otherwise the inertia matrix is unused. The damping matrix is optional. The combination of these matrices is referred to as a superelement. Three input cards are required for each superelement.

The degrees-of-freedom for this superelement may consist of generalized coordinates as well as nodal point quantities. Degrees-of-freedom, defined using *NODE input, are called attachment nodes. Only attachment nodes are included in the output to the ASCII and binary databases.

The matrices for a given superelement can be of different order. However, the explicit integration scheme requires the inversion of the union of the element mass matrix and nodal masses associated with attachment nodes. Any degree of freedom included in the other (stiffness, damping, inertia) matrices but without nonzero columns in the combined mass matrix will be viewed as massless and constrained not to move. After deleting zero rows and columns, the combined mass matrix is required to be positive definite.

The inertia matrix is required to have 3 columns which corresponds to the 3 global coordinates. It is used to compute the forces acting on the superelement by multiplying the inertia matrix times the gravitational acceleration specified using *LOAD_BODY_OPTION.

There is no assumption made on the order of the matrices nor the sparse matrix structure of the element matrices, except that they are symmetric and the combined mass matrix is invertible as described above.

Multiple elements may be input using *ELEMENT_DIRECT_MATRIX_INPUT. They may share attachment nodes with other direct matrix input elements. Only *BOUNDARY_PRESCRIBED_MOTION and global constraints imposed using *NODE or

*ELEMENT

*ELEMENT_DIRECT_MATRIX_INPUT

*BOUNDARY_SPC on attachment nodes can be applied in explicit applications. Implicit applications can have additional constraints on attachment nodes.

Damping can be added for these elemental matrices in two ways. The first is to include damping in the construction of the elemental matrices (see *CONTROL_IMPLICIT_MODES) by specifying the damping matrix in the DAMP field below. If the DAMP field is left blank, the damping can be imposed by using *DAMPING_GLOBAL or *DAMPING_PART_MASS.

VARIABLE

DESCRIPTION

EID Super element ID.

IFRMT Format:
EQ.0: standard format
NE.0: extended precision format

FILENAME Name of file that has the element matrices.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| MASS | Name of mass matrix in the file defined by FILENAME. This filename should be no more than eight characters to be compatible with NASTRAN. |
| DAMP | Name of damping matrix in the file defined by FILENAME. This filename should be no more than eight characters to be compatible with NASTRAN. |
| STIF | Name of stiffness matrix in the file defined by FILENAME. This filename should be no more than eight characters to be compatible with NASTRAN. |
| INERT | Name of inertia matrix in the file defined by FILENAME. This filename should be no more than eight characters to be compatible with NASTRAN. This file must be present when *LOAD_BODY is used to put gravitational forces on the model. |

*ELEMENT_DISCRETE_{OPTION}

Available options include:

<BLANK>

LCO

Purpose: Define a discrete (spring or damper) element between two nodes or a node and ground.

An option, LCO, is available for using a load curve(s) to initialize the offset to avoid the excitation of numerical noise that can sometimes result with an instantaneous imposition of the offset. This can be done using a single curve at the start of the calculation or two curves where the second is used during dynamic relaxation prior to beginning the transient part. In the latter case, the first curve would simply specify the offset as constant during time. If the LCO option is active, a second card is read.

Beam type 6, see *ELEMENT_BEAM and SECTION_BEAM, may be used as an alternative to *ELEMENT_DISCRETE and *SECTION_DISCRETE, and is recommended if the discrete element's line of action is not node N1 to N2, i.e., if VID \neq 0.

NOTE: The discrete elements enter into the time step calculations. Care must be taken to ensure that the nodal masses connected by the springs and dampers are defined and unrealistically high stiffness and damping values must be avoided. **All rotations are in radians.**

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|------|------|------|------|-----|-----|---|----|--------|----|
| Variable | EID | PID | N1 | N2 | VID | S | | PF | OFFSET | |
| Type | I | I | I | I | I | F | | I | F | |
| Default | none | none | none | none | 0 | 1.0 | | 0 | 0.0 | |

Offset Load Curve Card. Additional card for LCO keyword option.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|---|---|---|---|---|---|
| Variable | LCID | LCIDDR | | | | | | |
| Type | I | I | | | | | | |
| Default | none | none | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| EID | Element ID. A unique number is required. Since null beams are created for visualization, this element ID should not be identical to element ID's defined for *ELEMENT_BEAM and *ELEMENT_SEATBELT. |
| PID | Part ID, see *PART. |
| N1 | Nodal point 1. |
| N2 | Nodal point 2. If zero, the spring/damper connects node N1 to ground. |
| VID | Orientation option. The orientation option should be used cautiously since forces, which are generated as the nodal points displace, are not orthogonal to rigid body rotation unless the nodes are coincident. The type 6, 3D beam element, is recommended when orientation is required with the absolute value of the parameter SCOOR set to 2 or 3, since this option avoids rotational constraints. EQ.0: the spring/damper acts along the axis from node N1 to N2, NE.0: the spring/damper acts along the axis defined by the orientation vector, VID defined in the *DEFINE_SD_ORIENTATION section. |
| S | Scale factor on forces. |
| PF | Print flag: EQ.0: forces are printed in DEFORC file, EQ.1: forces are not printed DEFORC file. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| OFFSET | Initial offset. The initial offset is a displacement or rotation at time zero. For example, a positive offset on a translational spring will lead to a tensile force being developed at time zero. Ignore this input if LCID is defined below. |
| LCID | Load curve ID defining the initial OFFSET as a function of time. Positive offsets correspond to tensile forces, and, likewise negative offsets result in compressive forces. |
| LCIDDR | Load curve ID defining OFFSET as a function of time during the dynamic relaxation phase. |

***ELEMENT_DISCRETE_SPHERE_{OPTION}**

Available options include:

<BLANK>

VOLUME

Purpose: Define a discrete spherical element for discrete element method (DEM) calculations. Currently, LS-DYNA’s implementation of the DEM supports only spherical particles, as discrete element spheres (DES). Each DES consists of a single node with its mass, mass moment of inertia, and radius defined by the input below. Initial coordinates and velocities are specified using the nodal data. The element ID corresponds to the ID of the node. The discrete spherical elements are visualized in LS-PrePost using the same options as the SPH elements.

Please note, the DES part requires *PART, *SECTION, and *MAT keywords. The element type and formulation values in *SECTION are ignored. DEM retrieves the bulk modulus from the *MAT input for coupling stiffness and time step size evaluation, and density from the *MAT input if VOLUME is used to calculate the proper mass. *MAT_ELASTIC and *MAT_RIGID are most commonly used, but other material models are also permissible.

Card Summary:

Card 1a. This card is included if and only if the keyword option is unused.

| | | | | | | | |
|-----|-----|------|---------|--------|--|--|--|
| NID | PID | MASS | INERTIA | RADIUS | | | |
|-----|-----|------|---------|--------|--|--|--|

Card 1b. This card is included if and only if the VOLUME keyword option is used.

| | | | | | | | |
|-----|-----|--------|---------|--------|--|--|--|
| NID | PID | VOLUME | INERTIA | RADIUS | | | |
|-----|-----|--------|---------|--------|--|--|--|

Data Card Definitions:

ELEMENT**ELEMENT_DISCRETE_SPHERE**

| VARIABLE | DESCRIPTION |
|-----------------|--|
| NID | DES Node ID. |
| PID | DES Part ID, see *PART. |
| MASS | mass |
| INERTIA | Mass moment of inertia. |
| RADIUS | Particle radius. The particle radius is used for defining contact between particles. |

| Card 1b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|--------|---------|--------|---|---|---|
| Variable | NID | PID | VOLUME | INERTIA | RADIUS | | | |
| Type | I | I | F | F | F | | | |
| Default | none | none | none | none | none | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| NID | DES Node ID. |
| PID | DES Part ID, see *PART. |
| VOLUME | Volume. The mass is calculated from material density, $M = \text{VOLUME} \times \rho_{\text{mat}} .$ |
| INERTIA | Inertia per unit density. The actual inertia is calculated from material density, $I = \text{INERTIA} \times \rho_{\text{mat}} .$ |
| RADIUS | Particle radius. The particle radius is used for defining contact between particles. |

***ELEMENT_GENERALIZED_SHELL**

Purpose: Define a general 3D shell element with an arbitrary number of nodes. The formulation of this element is specified in *DEFINE_ELEMENT_GENERALIZED_SHELL, which is specified through the part ID (see *PART) and the section ID (see *SECTION_SHELL). For an illustration of this referencing, see [Figure 17-3](#). This generalized shell implementation allows for rapid prototyping of new shell element formulations without requiring further coding.

The element formulation used in *SECTION_SHELL needs to be greater or equal than 1000.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|---|---|---|---|---|
| Variable | EID | PID | NMNP | | | | | |
| Type | I | I | I | | | | | |
| Default | none | none | none | | | | | |

Connectivity Cards. Define the connectivity of the element by specifying NMNP-nodes (up to eight nodes per card). Include as many cards as needed. For example, for NMNP = 10, the deck should include two additional cards.

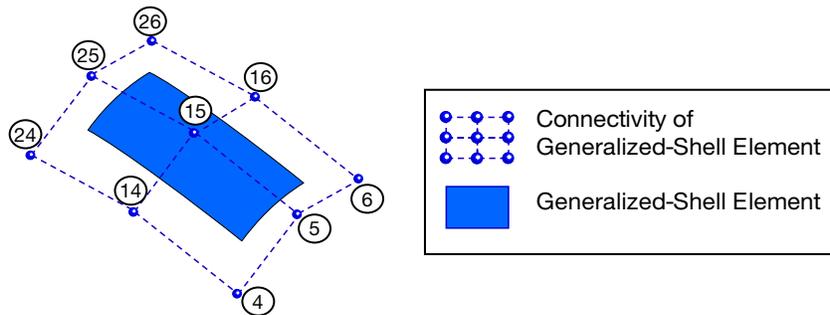

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | N1 | N2 | N3 | N4 | N5 | N6 | N7 | N8 |
| Type | I | I | I | I | I | I | I | I |
| Default | none |

VARIABLE**DESCRIPTION**

| | |
|-------|---|
| EID | Element ID. Chose a unique number with respect to other elements. |
| PID | Part ID, see *PART. |
| NMNP | Number of nodes to define this element. |
| N_i | Nodal point i (defined via *NODE) to define connectivity of this element. |

Remarks:

1. **Interpolation Shell Elements.** For post-processing and the treatment of contact boundary conditions, the use of interpolation shell elements (see *ELEMENT_INTERPOLATION_SHELL and *CONSTRAINED_NODE_INTERPOLATION) is necessary.
2. **Connectivity.** The definition of the connectivity of the element is basically arbitrary, but it has to correlate with the definition of the element formulation in *DEFINE_ELEMENT_GENERALIZED_SHELL.

Figure 17-3. Example of the connection between *ELEMENT_GENERALIZED_SHELL and *DEFINE_ELEMENT_GENERALIZED_SHELL.

***ELEMENT_GENERALIZED_SOLID**

Purpose: Define a general 3D solid element with an arbitrary number of nodes. The formulation of this element is specified in *DEFINE_ELEMENT_GENERALIZED_SOLID, which is referenced through the part ID (see *PART) and the section ID (see *SECTION_SOLID). For an illustration of this referencing, see [Figure 17-4](#). This generalized solid implementation allows for rapid prototyping of new solid element formulations without further coding.

The element formulation used in *SECTION_SOLID needs to be greater or equal than 1000.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|---|---|---|---|---|
| Variable | EID | PID | NMNP | | | | | |
| Type | I | I | I | | | | | |
| Default | none | none | none | | | | | |

Connectivity Cards. Define the connectivity of the element by specifying NMNP nodes (up to eight nodes per card). Include as many cards as needed. For example, for NMNP = 10, the deck should include two additional cards.

| Variable | IXX | IXY | IXZ | IYY | IYZ | IZZ | MASS | |
| Type | F | F | F | F | F | F | F | |
| Default | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | |
| Remarks | | 2 | 2 | | 2 | | | |

Offset Card. Additional card for offset keyword option.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|---|---|---|---|---|
| Variable | X-OFF | Y-OFF | Z-OFF | | | | | |
| Type | F | F | F | | | | | |
| Default | 0. | 0. | 0. | | | | | |
| Remarks | | 2 | 2 | | | | | |

VARIABLE**DESCRIPTION**

| | |
|-------|---|
| EID | Element ID. A unique number must be used. |
| NID | Node ID. Node to which the mass is assigned. |
| CSID | Coordinate system ID EQ.0: global inertia tensor GE.1: principal moments of inertias with orientation vectors defined by Coordinate system CSID. See *DEFINE_COORDINATE_SYSTEM and *DEFINE_COORDINATE_VECTOR. |
| IXX | <i>xx</i> component of inertia tensor. |
| IXY | <i>xy</i> component of inertia tensor. |
| IXZ | <i>xz</i> component of inertia tensor. |
| IYY | <i>yy</i> component of inertia tensor. |
| IYZ | <i>yz</i> component of inertia tensor. |
| IZZ | <i>zz</i> component of inertia tensor. |
| MASS | Lumped mass |
| X-OFF | <i>x</i> -offset from nodal point. |
| Y-OFF | <i>y</i> -offset from nodal point. |
| Z-OFF | <i>z</i> -offset from nodal point. |

Remarks:

1. **Coordinate System.** The coordinate system cannot be defined for this element using the option,

*DEFINE_COORDINATE_NODE.

2. **Nodal Inertia Tensor.** If CSID is defined, then IXY, IXZ and IYZ are set to zero. The nodal inertia tensor must be positive definite, that is, its determinant must be greater than zero, since its inverse is required. This check is done after the nodal inertia is added to the defined inertia tensor.

***ELEMENT_INTERPOLATION_SHELL**

Purpose: With the definition of interpolation shells, the stresses and other solution variables can be interpolated from the generalized shell elements (see *ELEMENT_GENERALIZED_SHELL and *DEFINE_ELEMENT_GENERALIZED_SHELL) permitting the solution to be visualized using standard 4-node shell elements with one integration point (one value of each solution variable per interpolation shell). The definition of the interpolation shells is based on interpolation nodes (see *CONSTRAINED_NODE_INTERPOLATION). The connections between these various keywords are illustrated in [Figure 17-5](#).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|------|---|---|---|---|---|
| Variable | EIDS | EIDGS | NGP | | | | | |
| Type | I | I | I | | | | | |
| Default | none | none | none | | | | | |

Weighting Factor Cards. These cards set the weighting factors used for interpolating the solution onto the center of *this* interpolation shell. Set one weight for each of the NGP integration points. Each card can accommodate 4 points; define as many cards as necessary. For example, if NGP = 10, three cards are required.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | IP1 | W1 | IP2 | W2 | IP3 | W3 | IP4 | W4 |
| Type | I | F | I | F | I | F | I | F |
| Default | none |

VARIABLE**DESCRIPTION**

| | |
|-------|--|
| EIDS | Element ID of the interpolation shell. This needs to coincide with a proper definition of a 4-node shell element (*ELEMENT_SHELL) using interpolation nodes (*CONSTRAINED_NODE_INTERPOLATION). |
| EIDGS | Element ID of the master element defined in *ELEMENT_GENERALIZED_SHELL. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| NGP | Number of in-plane integration points of the master element. |
| IP_i | Integration point number (1 to NGP) in the order they were defined in *DEFINE_ELEMENT_GENERALIZED_SHELL. |
| W_i | Interpolation weight of integration point i . |

Remarks:

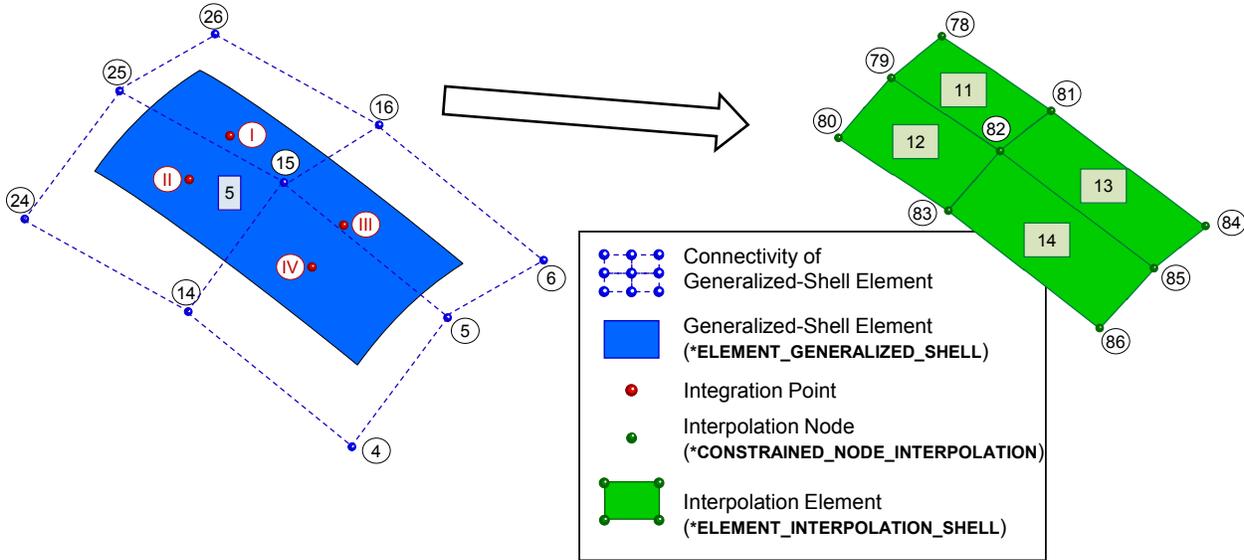

1. **Interpolation.** For each interpolation shell element, one single value (v_{IS}) of a solution variable is interpolated based on values at the integration points (v_i) of the master element (*ELEMENT_GENERALIZED_SHELL) and the appropriate weighting factors (w_i). The interpolation is computed as follows:

$$v_{IS} = \sum_{i=1}^{NGP} w_i v_i .$$

2. **Element Formulation.** To use *ELEMENT_INTERPOLATION_SHELL, ELFORM = 98 must be used in *SECTION_SHELL.

Figure 17-5. Example for *ELEMENT_INTERPOLATION_SHELL.

***ELEMENT_INTERPOLATION_SOLID**

Purpose: With the definition of interpolation solids, the stresses and other solution variables can be interpolated from the generalized solid elements (see *ELEMENT_GENERALIZED_SOLID and *DEFINE_ELEMENT_GENERALIZED_SOLID) permitting the solution to be visualized using standard 8-noded solid elements with one integration point (one value of each solution variable per interpolation solid). The definition of the interpolation solids is based on interpolation nodes (see *CONSTRAINED_NODE_INTERPOLATION). The connection between these various keywords are illustrated in [Figure17-6](#).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|------|---|---|---|---|---|
| Variable | EIDS | EIDGS | NGP | | | | | |
| Type | I | I | I | | | | | |
| Default | none | none | none | | | | | |

Weighting Factor Cards. These cards set the weighting factors used for interpolating the solution onto the center of *this* interpolation solid. Set one weight for each of the element's NGP integration points. Each card can accommodate 4 points; define as many cards as necessary. As an example, for NGP = 10 three cards are required.

| Cards | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | IP1 | W1 | IP2 | W2 | IP3 | W3 | IP4 | W4 |
| Type | I | F | I | F | I | F | I | F |
| Default | none |

VARIABLE**DESCRIPTION**

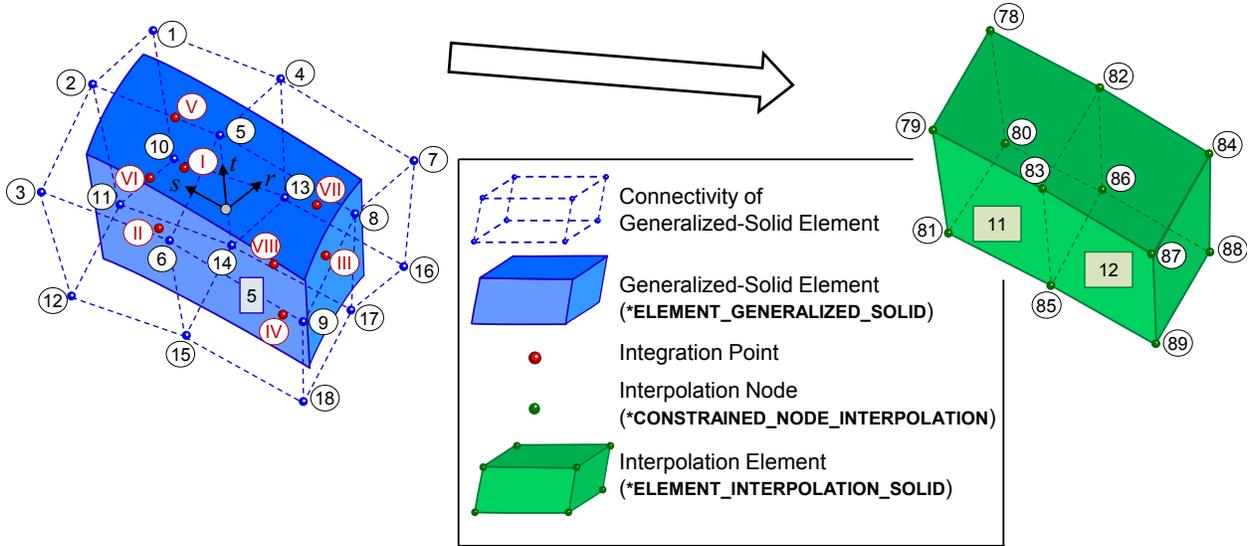

EIDS

Element ID of the interpolation solid. This needs to coincide with a proper definition of a 8-noded solid element (*ELEMENT_SOLID) using interpolation nodes (*CONSTRAINED_NODE_INTERPOLATION).

| VARIABLE | DESCRIPTION |
|------------------------|--|
| EIDGS | Element ID of the master element defined in *ELEMENT_GENERALIZED_SOLID. |
| NGP | Number of integration points of the master element. |
| IP _{<i>i</i>} | Integration point number (1 to NGP) in the order how they were defined in *DEFINE_ELEMENT_GENERALIZED_SOLID. |
| W _{<i>i</i>} | Interpolation weight of integration point <i>i</i> . |

Remarks:

1. For each interpolation solid element, one single value (v_{IS}) of a solution variable is interpolated based on values at the integration points (v_i) of the master element (*ELEMENT_GENERALIZED_SOLID) and the appropriate weighting factors (w_i). The interpolation is computed as follows:
$$v_{IS} = \sum_{i=1}^{NGP} w_i v_i$$
2. To use *ELEMENT_INTERPOLATION_SOLID, ELFORM = 98 has to be used in *SECTION_SOLID

```

Figure 17-6. Example for *ELEMENT INTERPOLATION SOLID.

***ELEMENT_LANCING**

Purpose: This feature models a lancing process during a metal forming process by trimming along a curve. Two types of lancing, instant and progressive, are supported. This keyword is used together with *DEFINE_CURVE_TRIM_3D, and only applies to shell elements. The lanced scraps can be removed (trimming) during or after lancing when used in conjunction with *DEFINE_LANCE_SEED_POINT_COORDINATES; see [Trimming](#) remarks below.

The element lancing feature is supported in LS-PrePost 4.3, under Application → MetalForming → Easy Setup.

For each trim include an additional card. This input ends at the next keyword (“*”) card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|---------|------|------|------|--------|------|
| Variable | IDPT | IDCV | IREFINE | SMIN | AT | ENDT | NTIMES | CIVD |
| Type | I | I | I | F | F | F | I | I |
| Default | none | none | 1 | none | none | ↓ | ↓ | ↓ |

VARIABLE**DESCRIPTION**

IDPT

A flag to indicate if a part to be lanced is a part or a part set.

GT.0: IDPT is the PID of a part to be lanced; see *PART.

LT.0: the absolute value is the part set ID as in *SET_PART_LIST. This option allows the lancing to be performed across a tailor-welded line.

IDCV

A trim curve ID (the variable TCID in *DEFINE_CURVE_TRIM_3D) defining a lancing route (see [Remarks](#)). XYZ format (TCTYPE = 1) has always been supported; however, IGES format (TCTYPE = 2) is not supported until Revision 110246.

IREFINE

Set IREFINE = 1 to refine elements along lancing route until no adapted nodes exist in the neighborhood. This feature results in a more robust lancing in the form of improved lancing boundary. Available starting in Revision 107708. Values greater than “1” are not allowed. See [Figure 17-15](#) for an example of the mesh refinement.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| SMIN | Minimum element characteristic length to be refined to (to be supported in the future). Currently, one level of refinement will be automatically done. |
| AT | Activation time for lancing operation. This variable needs to be defined for both instant and progressive lancing types (see Remarks). If CIVD is defined, AT becomes the distance from the punch home position. |
| ENDT | Lancing end time (for progressive lancing only). If CIVD is defined, ENDT becomes the distance from the punch home position. Do not define for instant lancing. |
| NTIMES | A progressive lancing operation is evenly divided into NTIMES segments between AT and ENDT; within each segment lancing is done instantly. Do not define for instant lancing. |
| CIVD | The load curve ID (LCID) to define the kinematics (time vs. velocity) of the tool, with VAD = 0; see *DEFINE_CURVE. When this variable is used, AT and ENDT will become the distances from the punch bottom position, unless the variables DT and BT are defined in *BOUNDARY_PRESCRIBED_MOTION_RIGID. See an example with CIVD . |

Remarks:

Lancing the blank during forming at strategic locations under controlled conditions alleviates thinning and necking of sheet metal panels. Typically, the blank is lanced in the last few millimeters before the punch reaches its home position. Being an unstable process, lancing is not favored by all stampers; nevertheless, many users have devised processes which would be impossible without lancing.

The benefits of lancing are illustrated in [Figure 17-7](#). In this figure two closed-loop holes are instantly lanced each along the C-pillar top (window opening area) and bottom (window regulator area) to improve the formability at those two corners. The right panel of [Figure 17-7](#) is lanced and suffers less thinning compared to the no-lancing case, which is shown in the left-panel. This keyword offers two types of lancing operations:

1. **Instant lancing.** Instant lancing cuts the sheet metal once along the defined curve at a time specified in the AT field.

2. **Progressive lancing.** The cut is spatially divided into NTIMES sub-lances traveling along the curve in the direction of definition. See [Figure 17-10](#). Progressive lancing starts at AT and ends at ENDT thereby achieving a gradual and even release along the curve.

Modeling Guidelines:

Some modeling guidelines and limitations are listed below:

1. Both closed-loop ([Figure 17-8](#)) and open-loop ([Figure 17-9](#)) lancing curves are supported. A lancing curve may not cross another lancing curve or itself.
2. Since progressive lancing starts from the beginning of the curve and proceeds towards the end, the direction of the curve needs to be defined to match the direction of the physical cut ([Figure 17-10](#)). The direction can be set using LS-PrePost. The menu option GeoTol → Measure with the Edge box checked can be used to show the direction of the curve. If the direction is not as desired, GeoTol → Rever can be used to reverse the direction.
3. The effect of NTIMES can be seen in [Figure 17-11](#). Compared with NTIMES of 6, setting NTIMES to a value of 20 results in a smoother lancing boundary and less stress concentration along the separated route.
4. Although the IGES format curve is supported by the keyword *DEFINE_CURVE_TRIM_3D, curves defined with the keyword and used for lancing must be specified using only the XYZ format (TCTYPE = 1 or 0) for revisions prior to Revision 110246. The manual entry in the keyword manual for the *INTERFACE_BLANKSIZE_DEVELOPMENT keyword outlines a procedure for converting an IGES file into the required XYZ format. Note the IGES format support for lancing is enabled starting in Revision 110246.
5. The first two points as well as the last two points of any progressive lancing curve must be separated so that LS-DYNA can correctly determine the direction of the curve.
6. The lancing curve needs to be much longer than the element sizes in the lancing area.
7. To prevent mesh distortion at the end of the lancing route ENDT must be defined to be less than the simulation completion time (slightly less is sufficient).
8. As currently implemented, lancing is assumed to be in the Z-direction. This keyword does not model lancing along the draw wall with surface normals nearly perpendicular to the Z-axis.

9. Tailor-welded blanks are supported; however, the lancing route should not cross the laser line, as currently only one part can be defined with one lancing curve.
10. Both *PARAMETER and *PARAMETER_EXPRESSION are supported for AT and ENDT as of Revision 92335. This makes it possible for users to input distance from punch home as onset of the lancing. Refer to [Figure 17-13](#), where a punch’s velocity profile is shown, the lancing activation time AT, is calculated based on the distance to home, “dhome” (the shaded area), punch travel velocity “vdraw”, and total simulation time “ENDTIME”. The variable CIVD implemented in Rev 110173 removes the need for the calculation of AT from punch distance to home.
11. Mesh adaptivity (*CONTROL_ADAPTIVE and the parameter “ADPOPT” under *PART) must be turned on during lancing.
12. All trim curves used to define lancing routes (*DEFINE_CURVE_TRIM_3D) must be placed after all other curves in the input deck. Furthermore, no curves defined by *DEFINE_CURVE_TRIM_3D that are not used for lancing should be present anywhere in the input deck. Note this restriction is removed starting in Revision 110316.
13. Only *DEFINE_CURVE_TRIM_3D (not_NEW) is supported. If defined curve is far away from the blank, it will be projected in the Z-direction onto the blank.
14. This keyword is input order sensitive: *DEFINE_CURVE_TRIM_3D must be placed after *ELEMENT_LANCING.

Application example:

A partial deck implementing instant lancing is listed below. A blank having a PID of 8 is being lanced along curves #119 and #202 instantly at 0.05 and 0.051 seconds, respectively.

```

A partial keyword deck implementing two progressive lances is listed below. Both lances travel along paths starting at the same coordinate value. A sheet blank having a part ID of 9 is progressively lanced along both curves (IDCV = 1 and 2) as defined by *DEFINE_CURVE_TRIM_3D. Both lancing operations commence at 0.05 seconds and finish at 0.053 seconds with 20 cuts along each curve in opposite directions. The lancing results are shown in [Figure 17-12](#). Note that the termination time is 53.875 seconds, which is slightly larger than the ENDT.

```

Trimming after lancing:

As shown in [Figure 17-14](#) and the following partial keyword file, the lanced scraps can be removed (trimming) after a lancing simulation. An extra keyword, *DEFINE_LANCE_SEED_POINT_COORDINATES is needed to define the portion that would remain after the lancing and trimming. It should be obvious that the lancing curve defined by *DEFINE_CURVE_TRIM_3D must form a closed loop. The following

example will trim a part ID 9 with a fully enclosed lancing curve #1, at time = 0.049 seconds. Since the termination time is 0.0525 seconds, the scrap will be deleted (trimmed off) before the simulation ends. The scrap, enclosed by the curve, is located outside of the seed node, defined by *DEFINE_LANCE_SEED_POINT_COORDINATES (starting in Revision 107262).

```

```

This feature also makes it possible to combine the trimming process with a forming simulation, saving a trimming step in a line-die process simulation by skipping writing out a formed dynain file and reading in the same file for the trimming simulation.

Lance-trimming with a part set, IGES curve, a seed node and CIVD:

The following partial keyword input shows instant lance-trimming across the weld line of a tailor-welded blank using the part set ID "blksid" 100, which consists of PIDs 1 and 9. The part set ID used for *ELEMENT_LANCING input is "idpt", which is set as the negative of blksid (-100). The lance-trimming curve ID 1117 is defined using the file lance4.iges in IGES format (TCTYPE = 2). The defined variable CIVD refers to the load curve ID 1115 under *DEFINE_CURVE, which is the kinematic curve for the upper die. The lancing starts at 15.5 mm (AT = 15.5) away from upper die bottom position. A lance seed coordinate (-382.0, -17.0, 76.0) is defined using the keyword *DEFINE_LANCE_SEED_POINT_COORDINATES, resulting in the lanced scrap piece being removed after lancing.

Revision information:

This feature is available starting in Revision 83562 for SMP and in Revision 94383 for MPP, in explicit dynamic calculation only. Later revisions incorporate various improvements. The list below provides revision information:

15. Revision 92335: support of *PARAMETER and *PARAMETER_EXPRESSION.
16. Revision 94383: MPP support of lancing is available.
17. Revision 107708: support IREFINE = 1.
18. Revision 107262: lancing with trimming is supported.
19. Revision 110173: CIVD is supported, and AT and ENDT become distances from punch home if CIVD is activated.
20. Revision 110177: support negative IDPT for part set ID, enabling lancing across the laser welded line.
21. Revision 110246: lancing curve definition in IGES format is supported.

Improved lanced boundary mesh with
IREFINE=1 after Revision 107708

Figure 17-15. Set IREFINE = 1 (Revision 107708 and later) for improved lanced boundary.

***ELEMENT_MASS_{OPTION}**

Available options include:

<BLANK>

NODE_SET

Purpose: Define a lumped mass element assigned to a nodal point or equally distributed to the nodes of a node set.

(Note: NODE_SET option is available starting with the R3 release of Version 971.)

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|------|------|------|---|-----|---|---|---|---|----|
| Variable | EID | ID | MASS | | PID | | | | | |
| Type | I | I | F | | I | | | | | |
| Default | none | none | 0. | | 0 | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| EID | Element ID. A unique number is recommended. The nodes in a node set share the same element ID. |
| ID | Node ID or node set ID if the NODE_SET option is active. This is the node or node set to which the mass is assigned. |
| MASS | Mass value. When the NODE_SET option is active, the mass is equally distributed to all nodes in a node set. |
| PID | Part ID. This input is optional. |

Remarks:

- Kinetic Energy Output.** Kinetic energy of lumped mass elements is output as kinetic energy of part 0 in matsum (*DATABASE_MATSUM) if IERODE is set to 1 on *CONTROL_OUTPUT.

*ELEMENT

*ELEMENT_MASS_MATRIX

*ELEMENT_MASS_MATRIX_{OPTION}

Available options include:

<BLANK>

NODE_SET

Purpose: Define a 6×6 symmetric nodal mass matrix assigned to a nodal point or each node within a node set. A node may not be included in more than one *ELEMENT_MASS_MATRIX(_NODE_SET) command.

VARIABLE**DESCRIPTION**

| | |
|----------|--|
| EID | Element ID. A unique number is recommended. The nodes in a node set share the same element ID. |
| ID | Node ID or node set ID if the NODE_SET option is active. This is the node or node set to which the mass is assigned. |
| CID | Local coordinate ID which defines the orientation of the mass matrix |
| M_{ij} | The ij^{th} term of the symmetric mass matrix. The lower triangular part of the matrix is defined. |

***ELEMENT_MASS_PART_{OPTION}**

Available options include:

<BLANK>

SET

Purpose: Define additional non-structural mass to be distributed by an area (shell) / volume (solid) or mass weighted distribution to all nodes of a given part, or part set, ID. As an option, the total mass can be defined and the additional non-structural mass is computed. This option applies to all part ID's defined by shell and solid elements.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|------|---------|---|---------|---|------|---|-----|---|----|
| Variable | ID | ADDMASS | | FINMASS | | LCID | | MWD | | |
| Type | I | F | | F | | I | | I | | |
| Default | none | 0. | | 0. | | 0 | | 0 | | |

VARIABLE**DESCRIPTION**

| | |
|---------|--|
| ID | Part or part set ID if the SET option is active. A unique number must be used. |
| ADDMASS | Added translational mass to be distributed to the nodes of the part ID or part set ID. Set to zero if FINMASS is nonzero. Since the additional mass is not included in the time step calculation of the elements in the PID or SID, ADDMASS must be greater than zero if FINMASS is zero. Multiple applications of mass using the SET option are treated by the additional masses being summed. For multiple mass applications to the same PID (<BLANK> option), only the last definition is used. |
| FINMASS | Final translational mass of the part ID or part set ID. The total mass of the PID or SID is computed and subtracted from the final mass of the part or part set to obtain the added translational mass, which must exceed zero. Set FINMASS to zero if ADDMASS is nonzero. FINMASS is available in the R3 release of version 971. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| LCID | Optional load curve ID to scale the added mass at time = 0. This curve defines the scale factor as a function versus time. The curve must start at unity at t = 0. This option applies to deformable bodies only. |
| MWD | Optional flag for mass-weighted distribution, valid for SET option only: EQ.0: non-structural mass is distributed by area(shell)/volume(solid) weighted distribution, EQ.1: non-structural mass is distributed by mass weighted, area*density*thickness(shell)/volume*density(solid), distribution. Mixed uses with MWD for the same part should be avoided. |

***ELEMENT_PLOTEL**

Purpose: Define a null beam element for visualization.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|------|------|------|---|---|---|---|---|---|----|
| Variable | EID | N1 | N2 | | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|-------|---|
| EID | Element ID. A unique number is required. Since null beams are created for visualization, this element ID should not be identical to element IDs defined for *ELEMENT_BEAM and *ELEMENT_DISCRETE. |
| PID | Part ID |
| N1 | Node 1 ID |
| N2 | Node 2 ID |
| SBRID | Retractor ID, see *ELEMENT_SEATBELT_RETRACTOR. |
| SLEN | Initial slack length. See Remark 2 . |
| N3 | Optional node 3 ID. When $N3 > 0$ and $N4 > 0$, the element becomes a shell seat belt element. The thickness of the shell seatbelt is defined in *SECTION_SHELL, not in *SECTION_SEATBELT. The shell-type seatbelt must be of a rectangular shape as shown in Figure 17-16 and contained in a logically regular mesh. See Remark 3 . |
| N4 | Node 4 ID, which is required if and only if N3 is defined. |

Figure 17-16. Definition of seatbelt shell elements. The ordering of the nodes and elements are important for seatbelt shells. See the input descriptions for SECTION_SHELL, ELEMENT_SEATBELT_RETRACTOR and ELEMENT_SEATBELT_SLIPRING.

Remarks:

1. **Retractor.** The retractor ID should be defined only if the element is initially *inside* a retractor, see *ELEMENT_SEATBELT_RETRACTOR.
2. **Forces and Slack Length.** Belt elements are single degree of freedom elements connecting two nodes. When the strain in an element is positive (that is, the current length is greater than the unstretched length), a tension force is calculated from the material characteristics and is applied along the current axis of the element to oppose further stretching. The unstretched length of the belt is taken as the initial distance between the two nodes defining the position of the element plus the initial slack length.

3. **Shell Elements.** Seatbelt shell elements are included as a feature as of version 971 and must be used with caution. The seatbelt shells distribute the loading on the surface of the dummy more realistically than the two node belt elements. For the seatbelt shells to work with sliprings and retractors it is necessary to use a logically regular mesh of quadrilateral elements. *A seatbelt defined by a part ID must not be disjoint.*
4. **Material ID.** 1D and 2D seatbelt elements may not share the same material ID.

***ELEMENT_SEATBELT_ACCELEROMETER**

Purpose: This keyword command defines an accelerometer. Contrary to the keyword name, an accelerometer need not be associated with a seat belt. The accelerometer is fixed to a rigid body containing the three nodes defined below. An accelerometer will exhibit considerably less numerical noise than a deformable node, thereby reporting more meaningful data to the user. Whenever computed accelerations are compared to experimental data, or whenever computed accelerations are compared between different runs, this feature is essential.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

| Default | none | none | none | none | 0 | 0 | 0. | |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| SBACID | Accelerometer ID. A unique number must be used. |
| NID1 | Node 1 ID |
| NID2 | Node 2 ID |
| NID3 | Node 3 ID |
| IGRAV | Gravitational accelerations due to body force loads: EQ.-6: z and x components removed from acceleration output EQ.-5: y and z components removed from acceleration output EQ.-4: x and y components removed from acceleration output EQ.-3: z component removed from acceleration output EQ.-2: y component removed from acceleration output EQ.-1: x component removed from acceleration output EQ.0: all components included in acceleration output EQ.1: all components removed from acceleration output GT.1: IGRAV is a curve ID defining the gravitation-flag versus time. The ordinate values, representing the gravitation-flag, can be -6, -5, -4, -3, -2, -1, 0 or 1, as de- |

| VARIABLE | DESCRIPTION |
|----------|--|
| INTOPT | <p data-bbox="612 254 1409 478">scribed above. For example, a curve with 4 data points of (0.,1), (10.,1), (10.000001,0), (200.,0) sets the gravitation flag to be 1 when time ≤ 10, and 0 when time > 10. In other words, all components of gravitational accelerations are removed when time $\leq 10.$, and then included when time > 10.0.</p> <p data-bbox="475 527 1409 716">Integration option. If the accelerometer undergoes rigid body translation without rotation, this option has no effect; however, if rotation occurs, INTOPT affects how translational velocities (and displacements) are calculated. Note that the acceleration values written to the nodout file are unaffected by INTOPT.</p> <p data-bbox="508 741 1409 846">EQ.0: velocities are integrated from the global accelerations and transformed into the local system of the accelerometer.</p> <p data-bbox="508 871 1409 940">EQ.1: velocities are integrated directly from the local accelerations of the accelerometer.</p> |
| MASS | <p data-bbox="475 993 1409 1142">Optional added mass for accelerometer. This mass is equally distributed to nodal points NID1, NID2, and NID3. This option avoids the need to use the *ELEMENT_MASS keyword input if additional mass is required.</p> |

Remarks:

The presence of the accelerometer means that the accelerations and velocities of node 1 will be output to **all** output files in local instead of global coordinates.

The local coordinate system is defined by the three nodes as follows:

1. local x from node 1 to node 2,
2. local z perpendicular to the plane containing nodes 1, 2, and 3 ($z = x \times a$), where a is from node 1 to node 3,
3. local $y = z \times x$.

The three nodes should all be part of the same rigid body. The local axis then rotates with the body.

*ELEMENT

*ELEMENT_SEATBELT_PRETENSIONER

*ELEMENT_SEATBELT_PRETENSIONER

Purpose: Define seat belt pretensioner. A combination with sensors and retractors is also possible.

VARIABLE

DESCRIPTION

| | |
|--------|---|
| SBPRID | Pretensioner ID. A unique number has to be used. |
| SBPRTY | Pretensioner type (see Activation): EQ.1: pyrotechnic retractor with force limits (see Type 1), EQ.2: pre-loaded spring becomes active (see Types 2 and 3), EQ.3: lock spring removed (see Types 2 and 3), EQ.4: force as a function of time retractor (see Type 4). EQ.5: pyrotechnic retractor (old type in version 950) but with optional force limiter, LMTFRC (see Type 1 and Type 5). EQ.6: combination of types 4 and 5 as described in Type 6 below. EQ.7: independent pretensioner/retractor (see Type 7). EQ.8: energy as a function of time retractor pretensioner with optional force limiter, LMTFRC (see Type 8). |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | EQ.9: energy as a function of time buckle or anchor pretensioner (see Type 9). |
| SBSID1 | Sensor 1, see *ELEMENT_SEATBELT_SENSOR. See Activation . |
| SBSID2 | Sensor 2, see *ELEMENT_SEATBELT_SENSOR. |
| SBSID3 | Sensor 3, see *ELEMENT_SEATBELT_SENSOR. |
| SBSID4 | Sensor 4, see *ELEMENT_SEATBELT_SENSOR. |
| SBRID | Retractor number (SBPRTY = 1, 4, 5, 6, 7 or 8) or spring element number (SBPRTY = 2, 3 or 9). |
| TIME | Time between sensor triggering and pretensioner acting. |
| PTLCID | Load curve for pretensioner (Time after activation, Pull-in) (SBPRTY = 1, 4, 5, 6, 7, 8 or 9). |
| LMTFRC | Optional limiting force for retractor type 5 or 8. If zero, this option is ignored. |

Activation:

To activate the pretensioner, the following sequence of events must occur:

1. Any one of up to four sensors must be triggered.
2. Then a user-defined time delay occurs.
3. Then the pretensioner acts.

At least one sensor should be defined.

Pretensioners allow modeling of seven types of active devices which tighten the belt during the initial stages of a crash. Types 1 and 5 implement a pyrotechnic device which spins the spool of a retractor, causing the belt to be reeled in. The user defines a pull-in as a function of time curve which applies once the pretensioner activates. Types 2 and 3 implement preloaded springs or torsion bars which move the buckle when released.

Types 2 and 3:

The pretensioner is associated with any type of spring element including rotational. Note that the preloaded spring, locking spring, and any restraints on the motion of the associated nodes are defined in the normal way; the action of the pretensioner is merely to cancel the force in one spring until (or after) it fires. With the second type, the force in the spring element is canceled out until the pretensioner is activated. In this case the spring in question is normally a stiff, linear spring which acts as a locking mechanism, preventing motion of the seat belt buckle relative to the vehicle. A preloaded spring is defined in parallel with the locking spring. This type avoids the problem of the buckle being free to “drift” before the pretensioner is activated. Types 4, 6, and 7, force types, are described below.

Type 1:

As of version 950 the type 1 (now type 5) pretensioner requires a load curve that tabulates the pull-in of the pretensioner as a function of time. This pretensioner type interacts with the retractor, forcing it to pull in by the amount of belt indicated. It works well, and does exactly what it says it will do, but it can be difficult to use because it has no regard for the forces being exerted on the belt. If a pull-in of 20 mm is specified at a particular time, then 20 mm of belt will be pulled in, even if this results in unrealistic forces in the seatbelt. Furthermore, there was no explicit way to turn this pretensioner off. Once defined, it overrode the retractor completely, and the amount of belt passing into or out of the retractor depended solely on the load curve specified.

For the 970 release of LS-DYNA, the behavior of the type 1 pretensioner was changed due to user feedback regarding these shortcomings. Each retractor has a loading (and optional unloading) curve that describes the force on the belt element as a function of the amount of belt that has been pulled out of the retractor since the retractor locked. The new type 1 pretensioner acts as a shift of this retractor load curve. An example will make this clear. Suppose at a particular time that 5 mm of belt material has left the retractor. The retractor will respond with a force corresponding to 5 mm pull-out on its loading curve. But suppose this retractor has a type 1 pretensioner defined, and at this instant of time the pretensioner specifies a pull-in of 20 mm. The retractor will then respond with a force that corresponds to (5mm + 20mm) on its loading curve. This results in a much larger force. The effect can be that belt material will be pulled in, but unlike in the 950 version, there is no guarantee. The benefit of this implementation is that the force as a function of pull-in load curve for the retractor is followed and no unrealistic forces are generated. Still, it may be difficult to produce realistic models using this option, so two new types of pretensioners have been added. These are available in 970 versions 1300 and later.

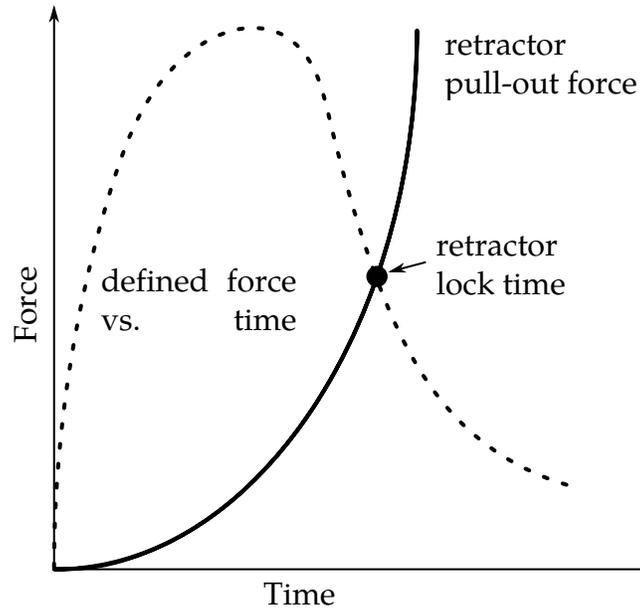

Figure 17-17. Force as a function of time for the pretensioner. At the intersection, the retractor locks.

Type 4:

The type 4 pretensioner requires a force as a function of time curve (see [Figure 17-17](#)). At each time step, the retractor computes the desired force without regard to the pretensioner. If the resulting force is less than that specified by the pretensioner load curve, then the pretensioner value is used instead. As time goes on, the pretensioner load curve should drop below the forces generated by the retractor, and the pretensioner is then essentially inactive. This provides for good control of the actual forces, so no unrealistic values are generated. The actual direction and amount of belt movement is unspecified, and will depend on the other forces being exerted on the belt. This is suitable when the force the pretensioner exerts over time is known.

Type 5:

The type 5 pretensioner is essentially the same as the old type 1 pretensioner, but with the addition of a force limiting value. The pull-in is given as a function of time, and the belt is drawn into the retractor exactly as desired. However, if at any point the forces generated in the belt exceed the pretensioner force limit, then the pretensioner is deactivated and the retractor takes over. In order to prevent a large discontinuity in the force at this point, the loading curve for the retractor is shifted (in the abscissa) by the

amount required to put the current $\left(\text{pull-out,force} \right)$ on the load curve. For example,

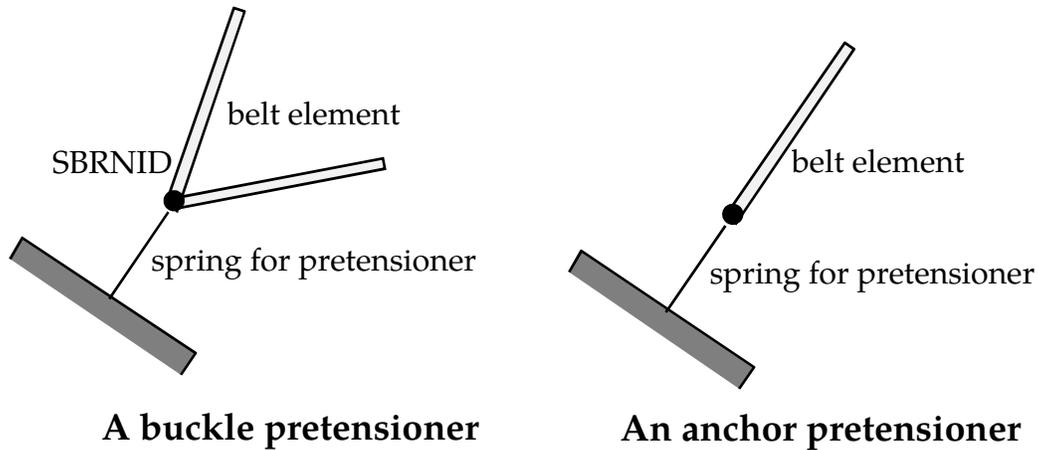

Figure 17-18. Schematics of different kinds of pretensioners.

suppose the current force is 1000, and the current pull-out is -10 (10 mm of belt has been *pulled in* by the pretensioner). If the retractor would normally generate a force of 1000 after 25 mm of belt had been *pulled out*, then the load curve is shifted to the left by 35, and remains that way for the duration of the calculation. So that at the current pull-in of 10, it will generate the force normally associated with a pull-out of 25. If the belt reaches a pull-out of 5, the force will be as if it were pulled out 40 (5 + the shift of 35), and so on. This option is included for those who liked the general behavior of the old type 1 pretensioner, but has the added feature of the force limit to prevent unrealistic behavior.

Type 6:

The type 6 pretensioner is a variation of the type 4 pretensioner, with features of the type 5 pretensioner. A force as a function of time curve is input and the pretensioner force is computed each cycle. The retractor linked to this pretensioner should specify a positive value for pull, which is the distance the belt pulls out before it locks. As the pretensioner pulls the belt into the retractor, the amount of pull-in is tracked. As the pretensioner force decreases and drops below the belt tension, belt will begin to move back out of the retractor. Once pull amount of belt has moved out of the retractor (relative to the maximum pull in encountered), the retractor will lock. At this time, the pretensioner is disabled, and the retractor force curve is shifted to match the current belt tension. This shifting is done just like the type 5 pretensioner. It is important that a positive value of pull be specified to prevent premature retractor locking which could occur due to small outward belt movements generated by noise in the simulation.

Type 7:

The type 7 pretensioner is a simple combination of retractor and pretensioner. It is similar to the type 6 pretensioner except for the following changes:

1. when the retractor locks, the pretensioner is *not* disabled – it continues to exert force according to the force as a function of time curve until the end of the simulation. (The force as a function of time curve should probably drop to 0 at some time.)
2. The retractor load curve is not shifted – the retractor begins to exert force according to the force as a function of pull-out curve. These two forces are added together and applied to the belt. Thus, the pretensioner and retractor are essentially independent.

Type 8:

The type 8 pretensioner is a variation of the type 5 pretensioner. The pretension energy, instead of pull-in for type 5, is given as a function of time. This enables users to use a single pretensioner curve, PTLCID, for various sizes of dummies. The energy could be yielded from the baseline test or simulation by

$$E(t) = \int_0^t f dp ,$$

where f is the force of the mouth element of the retractor and dp is the incremental pull-in.

Type 9:

The type 9 pretensioner is designed for a pretension-energy based buckle or anchor pretensioner. The pretensioner is modeled as a spring element, SBRID. One end of the spring element is attached to the vehicle. For a buckle pretensioner, the other end of SBRID is the slip ring node, SBRNID, of a slip ring representing the buckle. For an anchor pretensioner, SBRID shares the other end with a belt element; see [Figure 17-18](#).

VARIABLE

DESCRIPTION

| | |
|--------|---|
| SBRID | Retractor ID. A unique number has to be used. |
| SBRNID | Retractor node ID |
| SBID | Seat belt element ID |
| SID1 | Sensor ID 1 |
| SID2 | Sensor ID 2 |
| SID3 | Sensor ID 3 |
| SID4 | Sensor ID 4 |

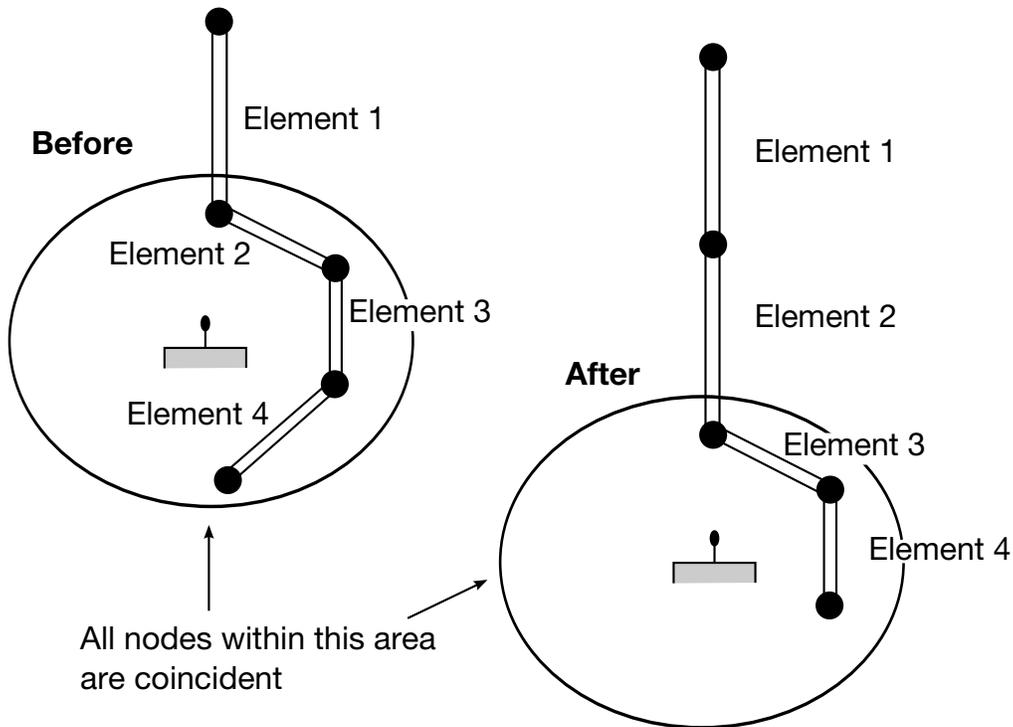

Figure 17-19. Elements in a retractor.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| TDEL | Time delay after sensor triggers. |
| PULL | Amount of pull-out between time delay ending and retractor locking, a length value. |
| LLCID | Load curve for loading $\left(\text{Pull-out, Force} \right)$; see Figure 17-19 . |
| ULCID | Load curve for unloading $\left(\text{Pull-out, Force} \right)$; see Figure 17-19 . |
| LFED | Fed length |

Remarks:

1. **Retractor Node and Belt Elements.** The retractor node should not be on any belt elements. The element defined should have one node coincident with the retractor node but should not be inside the retractor.

2. **Shell-Type Seatbelt.** When $SBRNID < 0$, this retractor is for shell-type seatbelt, $-SBRNID$ is the `*SET_NODE` containing $RN1, RN2, \dots, RN5$. $SBID$ is then a `*SET_SHELL_LIST`. Note that the numbering of $-SBRNID$ and $SBID$ must be consistent in the direction of numbering. For example, if `*SET_NODE` for $SBRNID$ has nodes of $(RN1, RN2, RN3, RN4, RN5)$, then `*SET_SHELL_LIST` for $SBID$ should have elem. of $(RE1, RE2, RE3, RE4)$. See [Figure 17-16](#).
3. **Sensor Definitions.** At least one sensor should be defined.
4. **Loading Curve.** The first point of the load curve should be $(0, T_{min})$. T_{min} is the minimum tension. All subsequent tension values should be greater than T_{min} .
5. **Unloading Curve.** The unloading curve should start at zero tension and increase monotonically (i.e., no segments of negative or zero slope).
6. **Retractor Characteristics and Loading.** Retractors allow belt material to be paid out into a belt element. Retractors operate in one of two regimes: unlocked when the belt material is paid out, or reeled in under constant tension and locked when a user defined force-pullout relationship applies.

The retractor is initially unlocked, and the following sequence of events must occur for it to become locked:

- a) Any one of up to four sensors must be triggered. (The sensors are described below.)
- b) Then a user-defined time delay occurs.
- c) Then a user-defined length of belt must be paid out (optional).
- d) Then the retractor locks and once locked, it remains locked.

In the unlocked regime, the retractor attempts to apply a constant tension to the belt. This feature allows an initial tightening of the belt and takes up any slack whenever it occurs. The tension value is taken from the first point on the force-pullout load curve. The maximum rate of pull out or pull in is given by $0.01 \times \text{fed length per time step}$. Because of this, the constant tension value is not always achieved.

In the locked regime, a user-defined curve describes the relationship between the force in the attached element and the amount of belt material paid out. If the tension in the belt subsequently relaxes, a different user-defined curve applies for unloading. The unloading curve is followed until the minimum tension is reached.

The curves are defined in terms of initial length of belt. For example, if a belt is marked at 10 mm intervals and then wound onto a retractor, and the force required to make each mark emerge from the (locked) retractor is recorded, the curves used for input would be as follows:

- 0 Minimum tension (should be > zero)
- 10 mm Force to emergence of first mark
- 20 mm Force to emergence of second mark
- ⋮

Pyrotechnic pretensions may be defined which cause the retractor to pull in the belt at a predetermined rate. This overrides the retractor force-pullout relationship from the moment when the pretensioner activates.

7. **Multiple Belt Elements.** If desired, belt elements may be defined which are initially inside the retractor. These will emerge as belt material is paid out, and may return into the retractor if sufficient material is reeled in during unloading. For example, elements e2, e3 and e4 are initially inside the retractor, which is paying out material into element e1. When the retractor has fed L_{crit} into e1, where

$$L_{crit} = LFED - 1.1 \times LMIN$$

in which LMIN is the minimum length defined on the belt material input (see *MAT_SEAT) and LFED is the fed length, element e2 emerges with an unstretched length of $1.1 \times$ minimum length; the unstretched length of element e1 is reduced by the same amount. The force and strain in e1 are unchanged; in e2, they are set equal to those in e1. The retractor now pays out material into e2.

If no elements are inside the retractor, e2 can continue to extend as more material is fed into it.

As the retractor pulls in the belt (for example, during initial tightening), if the unstretched length of the mouth element becomes less than the minimum length, the element is taken into the retractor.

8. **Defining a Retractor.** To define a retractor, the user enters the retractor node, the 'mouth' element (into which belt material will be fed), which is shown as e1 in [Figure 17-19](#). Up to 4 sensors which can trigger unlocking, a time delay, a payout delay (optional), load and unload curve numbers, and the fed length are also defined. The retractor node is typically part of the vehicle structure; belt elements should not be connected to this node directly, but any other feature can be attached including rigid bodies. The mouth element should have a node coincident with the retractor but should not be inside the retractor. The

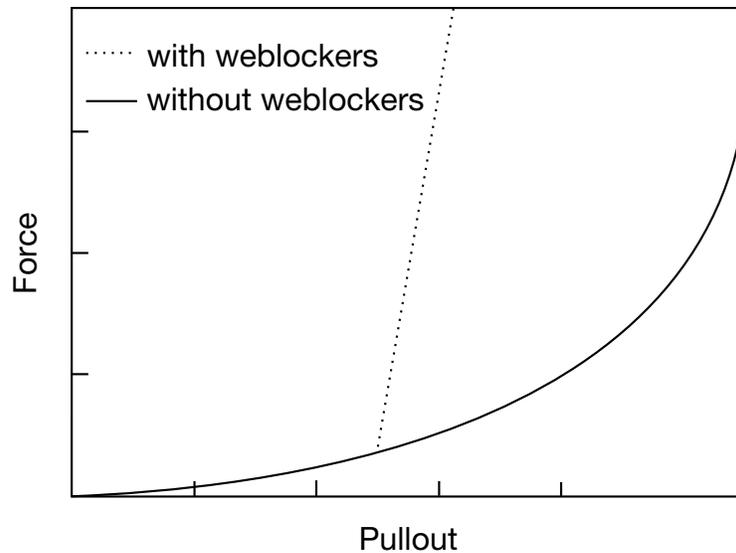

Figure 17-20. Retractor force pull characteristics.

fed length would typically be set either to a typical element initial length, for the distance between painted marks on a real belt for comparisons with high speed film. The fed length should be at least three times the minimum length.

If there are elements initially inside the retractor (e2, e3 and e4 in [Figure 17-19](#)), they should not be referred to on the retractor input, but the retractor should be identified on the element input for these elements. Their nodes should all be coincident with the retractor node and should not be restrained or constrained. Initial slack will automatically be set to $1.1 \times$ minimum length for these elements; this overrides any user-defined value.

Weblockers can be included within the retractor representation simply by entering a 'locking up' characteristic in the force pullout curve, see [Figure 17-20](#). The final section can be very steep (but must have a finite slope).

- 9. Locking and Pretensioners.** In an event when only retractors are used in the model, be aware that the pull-out is measured from the point when the retractor is locked. If the belt has been pulled IN since the retractor was locked, then minimum force will be seen in the retractor until the system pays out enough belt to get back to the point when locked.

If the behavior described in the above note undesirable, then the type 6 pretensioner model is recommended for the seat belt system. A constant force as a function of time load curve with a force equal to minimum tension will be defined, with a small PULL value on the retractor. With this set up, the pretensioner will be active until the belt pulls all the way in, but as soon as the belt starts to move back out, the pretensioner will get disabled and the retractor will take over.

*ELEMENT_SEATBELT_SENSOR

Purpose: Define seat belt sensor. Four types are possible; see Remark 3.

Card Summary:

Card 1. This card is required.

| | | | | | | | |
|-------|--------|-------|--|--|--|--|--|

| Remarks | | | 2 | 2 | | | | |

VARIABLE**DESCRIPTION**

| | |
|------|------------------|
| NID1 | Node 1 ID |
| NID2 | Node 2 ID |
| DMX | Maximum distance |
| DMN | Minimum distance |

Remarks:

1. **Node ID for Acceleration of Node Sensor.** Node should not be on rigid body, velocity boundary condition, or other 'imposed motion' feature.
2. **Distance Sensor.** Sensor triggers when the distance between the two nodes is $d \geq d_{\max}$ or $d \leq d_{\min}$.
3. **Sensor Types.** Sensors are used to trigger locking of retractors and to activate pretensioners. Four types of sensors are available which trigger according to the following criteria:

Type 1: When the magnitude of x -, y -, or z -acceleration of a given node has remained above a given level continuously for a given time, the sensor triggers. This does not work with nodes on rigid bodies.

Type 2: When the rate of belt payout from a given retractor has remained above a given level continuously for a given time, the sensor triggers.

Type 3: The sensor triggers at a given time.

Type 4: The sensor triggers when the distance between two nodes exceeds a given maximum or becomes less than a given minimum. This type of sensor is intended for use with an explicit mass/spring representation of the sensor mechanism.

By default, the sensors are inactive during dynamic relaxation. This allows initial tightening of the belt and positioning of the occupant on the seat without locking the retractor or firing any pretensioners. However, a flag can be set in the sensor input to make the sensors active during the dynamic relaxation phase.

*ELEMENT

*ELEMENT_SEATBELT_SLIPRING

*ELEMENT_SEATBELT_SLIPRING

Purpose: Define seat belt slip ring.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

| Type | F | I | I | F | | I | I | |
| Default | 0.0 | 0 | 0 | 0.0 | | 0 | 0 | |

VARIABLE

DESCRIPTION

| | |
|--------|---|
| SBSRID | Slip ring ID. A unique number has to be used. See Remark 3 below for the treatment of slip rings for shell belt elements. |
| SBID1 | Seat belt element 1 ID |
| SBID2 | Seat belt element 2 ID |
| FC | Coulomb dynamic friction coefficient. If less than zero, FC refers to a curve which defines the dynamic friction coefficient as a function of time. |
| SBRNID | Slip ring node, NID |
| LTIME | Slip ring lockup time. After this time no material is moved from one side of the slip ring to the other. This option is not active during dynamic relaxation. |

| VARIABLE | DESCRIPTION |
|----------|--|
| FCS | Optional Coulomb static friction coefficient. If less than zero, FCS refers to a curve which defines the static friction coefficient as a function of time. |
| ONID | Optional orientation node ID. |
| K | Optional coefficient for determining the Coulomb friction coefficient related to angle α (see Figure 17-24). See Remark 4 . |
| FUNCID | Function ID to determine friction coefficient. |
| DIRECT | Direction of belt movement. To disable the belt slip behavior imposed by DIRECT, see the Remark "Seatbelt Slip Ring" under *SENSOR_CONTROL. EQ.0: if the belt can move along both directions. EQ.12: if the belt is only allowed to slip along the direction from SBID1 to SBID2. EQ.21: if the belt is only allowed to slip along the direction from SBID2 to SBID1. |
| DC | Optional decay constant to allow a smooth transition between the static and dynamic friction coefficients, that is, $\mu_c = FC + (FCS - FC)e^{-DC \times v_{rel} }$ |
| LCNFFD | Optional curve for normal-force-dependent Coulomb dynamic friction coefficient. When defined, the dynamic friction coefficient becomes $FC + f_{LCNFFD}(F_n)$, where $f_{LCNFFD}(F_n)$ is the function value of LCNFFD at contact force F_n . |
| LCNFFS | Optional curve for normal-force-dependent Coulomb static friction coefficient. When defined, the static friction coefficient becomes $FCS + f_{LCNFFS}(F_n)$, where $f_{LCNFFS}(F_n)$ is the function value of LCNFFS at contact force F_n . |

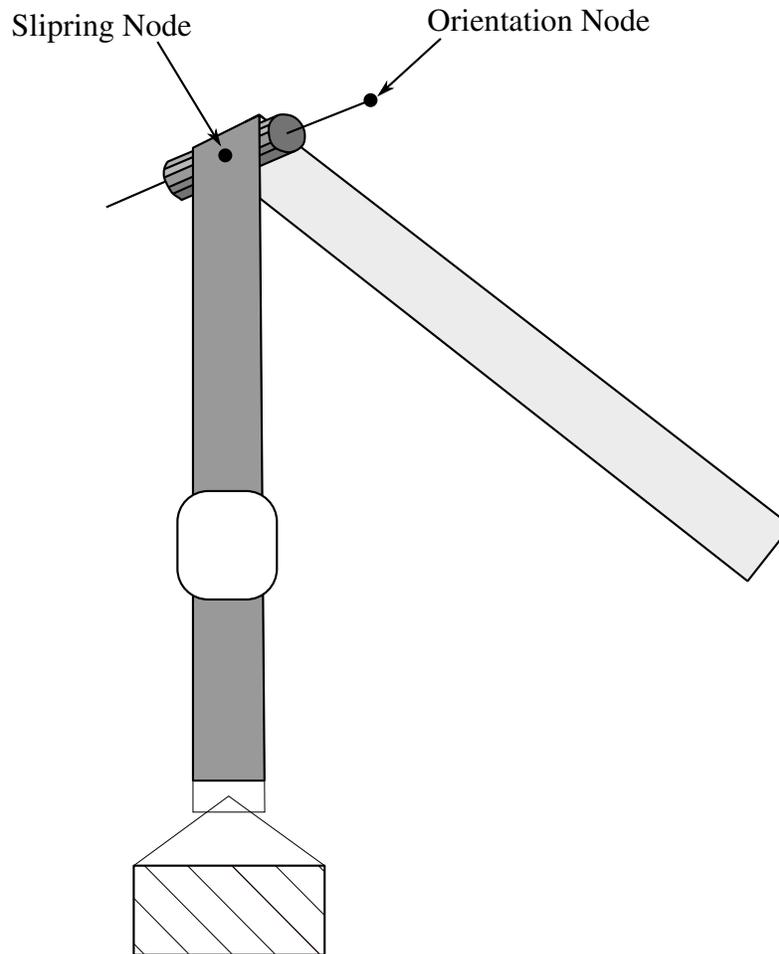

Figure 17-21. Orientation node.

Remarks:

1. **Slip Ring Model.** Slip rings allow continuous sliding of a belt through a sharp change of angle. To define a slip ring, the user identifies the two belt elements which meet at the slip ring (such as Elements 1 and 2 shown in [Figure 17-22](#)), the friction coefficient, and the slip ring node. The two elements must have a common node coincident with the slip ring node and should not be referenced by any other slip ring definition. No attempt should be made to restrain or constrain the common node because its motion will automatically be constrained to follow the slip ring node. Typically, the slip ring node is part of the vehicle body structure; therefore, belt elements should not be connected to this node directly, but any other feature can be attached, including rigid bodies.

As shown in [Figure 17-22](#), during slip Node B in the belt material remains attached to the slip ring node, but belt material (in the form of unstretched length) is passed from Element 1 to Element 2 to achieve slip. The amount of slip at each time step is calculated from the ratio of forces in Elements 1 and 2.

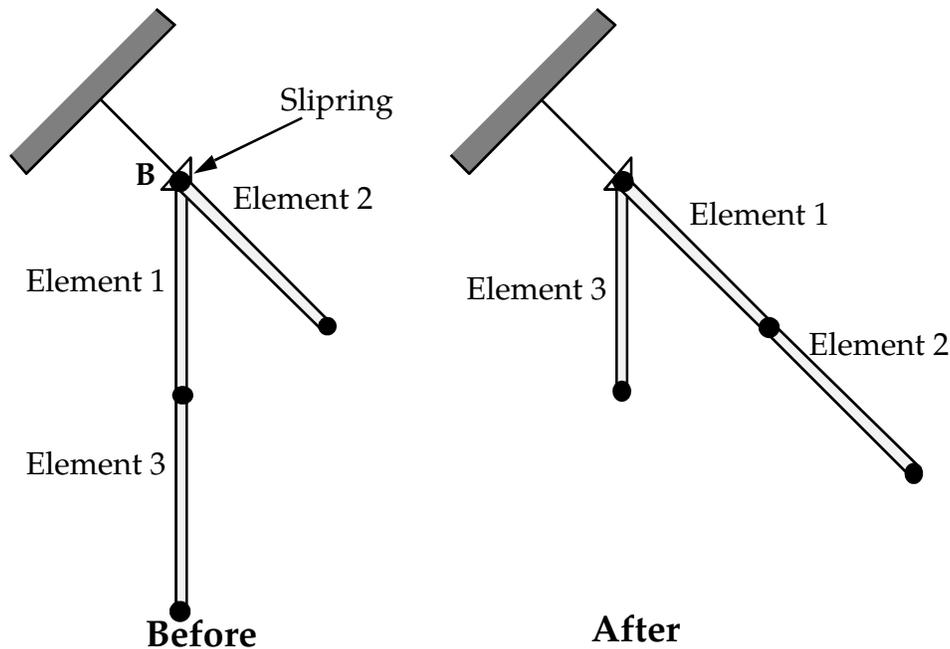

Figure 17-22. Elements passing through slipping.

The ratio of forces is determined by the relative angle between the elements and the coefficient of friction, FC. The tension in the belts are T_1 and T_2 , where T_2 is on the high tension side and T_1 is the force on the low tension side. Thus, if T_2 is sufficiently close to T_1 , no slip occurs; otherwise, slip is just sufficient to reduce the ratio T_2/T_1 to $e^{FC \times \theta}$, where θ is the wrap angle; see [Figures 17-21](#) and [17-23](#). No slip occurs if both elements are slack. The out-of-balance force at Node B is reacted on the slip ring node; the motion of node B follows that of slip ring node.

2. **Local Remeshing.** If, due to slip through the slip ring, the unstretched length of an element becomes less than the minimum length (as entered on the belt material card), the belt is remeshed locally: the short element passes through the slip ring and reappears on the other side (see [Figure 17-22](#)). The new unstretched length of element 1 is $1.1 \times$ minimum length. Force and strain in elements 2 and 3 are unchanged; force and strain in element 1 are now equal to those in element 2. Subsequent slip will pass material from element 3 to element 1. This process can continue with several elements passing in turn through the slip ring.
3. **Shell Elements.** When $SBRNID < 0$, this slip ring is for shell-type seatbelt; -SBRNID is the *SET_NODE containing SN1, SN2, ...SN5. SBID1 and SBID2 are then *SET_SHELL_LIST. Note that the numbering of -SBRNID, SBID1 and SBID2 has to be consistent in the direction of numbering. For example, if *SET_NODE for SBRNID has nodes (SN1, SN2, SN3, SN4, SN5) then *SET_SHELL_LIST for SBID1 should have elements (SRE11, SRE12, SRE13, SRE14)

and *SET_SHELL_LIST for SBID2 should have elements (SRE21, SRE22, SRE23, SRE24). See [Figure 17-21](#).

4. **Coulomb Friction.** If K is undefined, the limiting force ratio is taken as $e^{FC \times \theta}$. If K is defined, the maximum force ratio is computed as

$$e^{FC \times \theta (1 + K \times \alpha^2)},$$

where α is the angle shown in [Figure 17-24](#). The function is defined using the *DEFINE_FUNCTION keyword input. This function is a function of three variables, and the ratio is given by evaluating

$$\frac{T_2}{T_1} = \text{FUNC}(\text{FCT}, \theta, \alpha),$$

where FCT is the instantaneous friction coefficient at time t , that is, it has the value of FC if the belt has moved in the last time-step and the value of FCS if the belt has been stationary. For example, the default behavior can be obtained using the function definition (assuming FCT has a value of 0.025 and the function ID is 1):

```
*DEFINE_FUNCTION
  1,
f(fct,theta,alpha) = exp(0.025*theta)
```

Behavior like the default option can be obtained with (K = 0.1):

```
*DEFINE_FUNCTION
  1,
f(fct,theta,alpha) = exp(0.025*theta*(1.+0.1*alpha*alpha))
```

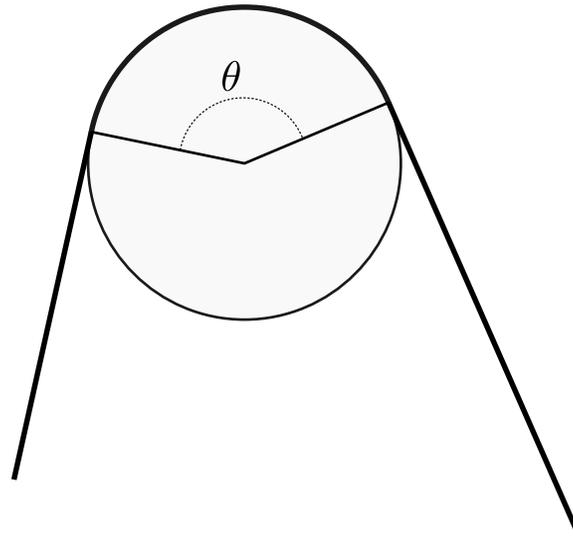

Figure 17-23. Front view showing wrap angle.

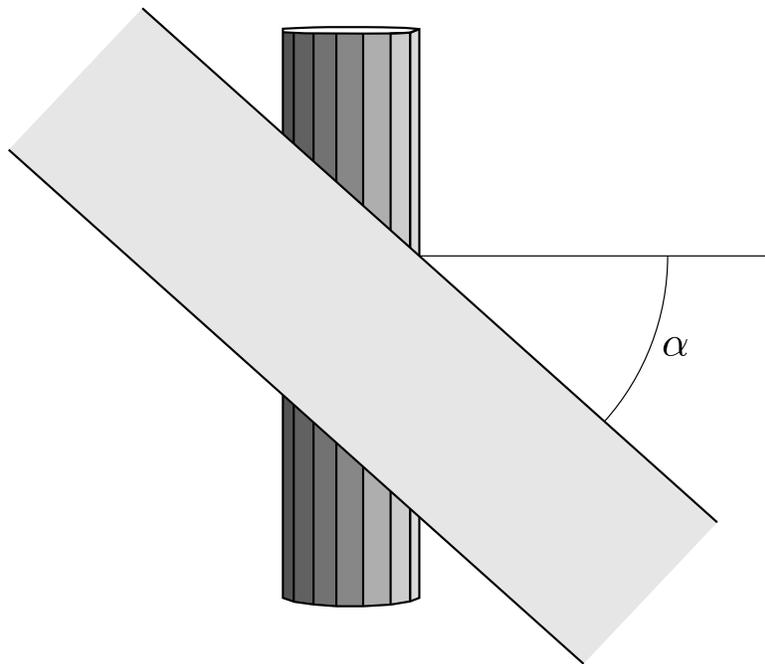

Figure 17-24. Top view shows orientation of belt relative to axis.

***ELEMENT_SHELL_{OPTION}**

Available options include:

<BLANK>

THICKNESS

BETA or MCID

OFFSET

DOF

COMPOSITE

COMPOSITE_LONG

SHL4_TO_SHL8

Stacking of options, e.g., THICKNESS_OFFSET, is allowed in some cases. When combining options in this manner, check d3hsp to confirm that all the options are acknowledged.

Purpose: Define three, four, six, and eight node elements including 3D shells, membranes, 2D plane stress, plane strain, and axisymmetric solids. The type of the element and its formulation is specified through the part ID (see *PART) and the section ID (see *SECTION_SHELL). Also, the thickness of each element can be specified when applicable on the element cards or else a default thickness value is used from the section definition.

For orthotropic and anisotropic materials, a local material angle (variable BETA) can be defined which is cumulative with the integration point angles specified in *SECTION_SHELL, *PART_COMPOSITE, *ELEMENT_SHELL_COMPOSITE, or *ELEMENT_SHELL_COMPOSITE_LONG. Alternatively, the material coordinate system can be defined as the projection of a local coordinate system, MCID, onto the shell.

An offset option, OFFSET, is available for moving the shell reference surface from the nodal points that define the shell.

The COMPOSITE or COMPOSITE_LONG option allows an arbitrary number of integration points across the thickness of shells sharing the same part ID. This is independent of thickness defined in *SECTION_SHELL. To maintain a direct association of through-thickness integration point numbers with physical plies in the case where the number of plies varies from element to element, see [Remark 12](#).

The option, SHL4_TO_SHL8, converts 3 node triangular and 4 node quadrilateral shell elements to 6 node triangular and 8 node quadrilateral quadratic shell elements, respectively, by the addition of mid-side nodal points. See [Remark 9](#) below.

For the shell formulation that uses additional nodal degrees-of-freedom, the option DOF is available to connect the nodes of the shell to corresponding scalar nodes. Four scalar nodes are required for element type 25 to model the thickness changes that require 2 additional degrees-of-freedom per shell node. Defining these nodes is optional; if left undefined, they will be automatically created.

COMPOSITE Cards. Additional set of cards for the COMPOSITE keyword option. Values of material ID, thickness, and material angle for each through-thickness integration point of a composite shell are defined using these cards (up to two integration points per card), and these values overrule values specified elsewhere. The integration point data should be given sequentially starting with the bottommost integration point. The total number of integration points is determined by the number of entries on these cards. The thickness of each shell is the summation of the integration point thicknesses. Define as many cards as needed.

| Variable | MID1 | THICK1 | B1 | | PLYID1 | | | |
| Type | I | F | F | | I | | | |

VARIABLE**DESCRIPTION**

| | |
|-----|---|
| EID | Element ID. Chose a unique number with respect to other elements. |
| PID | Part ID, see *PART. |
| N1 | Nodal point 1 |
| N2 | Nodal point 2 |
| N3 | Nodal point 3 |
| N4 | Nodal point 4 |

| VARIABLE | DESCRIPTION |
|---------------------------|--|
| N5 - N8 | Mid-side nodes for eight node shell |
| THIC1 | Shell thickness at node 1 |
| THIC2 | Shell thickness at node 2 |
| THIC3 | Shell thickness at node 3 |
| THIC4 | Shell thickness at node 4 |
| BETA | Orthotropic material base offset angle (see Remarks 5 and 6 below). The angle is given in degrees. If blank, the default is set to zero. |
| MCID | Material coordinate system ID. The a -axis of the base (or element-level) material coordinate system is the projection of the <i>x</i> -axis of coordinate system MCID onto the surface of the shell element. The c -axis of the material coordinate system aligns with the shell normal. The b -axis is taken as $\mathbf{b} = \mathbf{c} \times \mathbf{a}$. Each layer in the element can have a unique material orientation by defining a rotation angle for each layer as described in Remark 5 . |
| THIC5 | Shell thickness at node 5 |
| THIC6 | Shell thickness at node 6 |
| THIC7 | Shell thickness at node 7 |
| THIC8 | Shell thickness at node 8 |
| OFFSET | The offset distance from the plane of the nodal points to the reference surface of the shell in the direction of the normal vector to the shell. |
| NS1 | Scalar node 1, parameter NDOF on the *NODE_SCALAR is normally set to 2. If the thickness is constrained, set NDOF = 0. |
| NS2 | Scalar node 2 |
| NS3 | Scalar node 3 |
| NS4 | Scalar node 4 |
| MID _{<i>i</i>} | Material ID of integration point <i>i</i> , see *MAT_... Section. |
| THICK _{<i>i</i>} | Thickness of integration point <i>i</i> . |

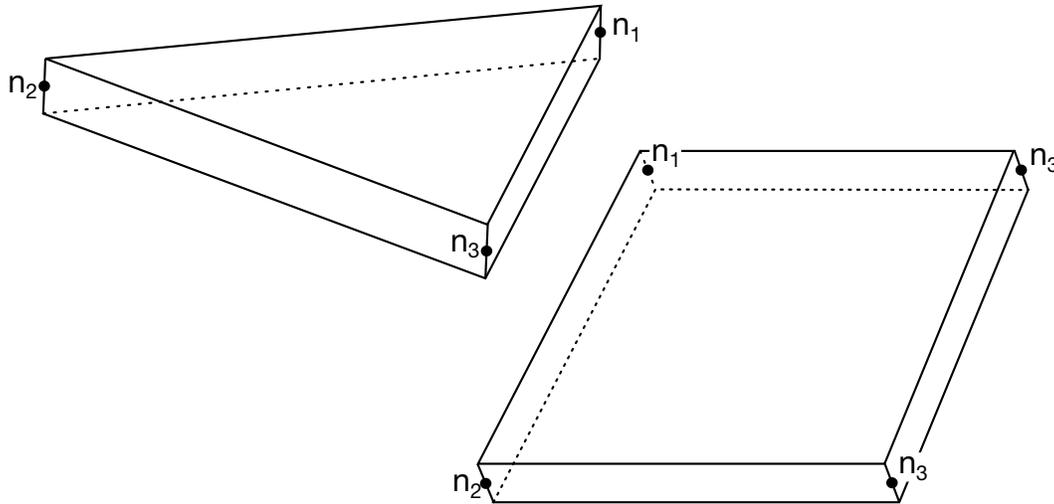

Figure 17-25. LS-DYNA shell elements. Counterclockwise node numbering determines the top surface.

| VARIABLE | DESCRIPTION |
|-----------|--|
| B_i | Material angle of integration point i . |
| PLYID i | Ply ID for integration point i (for post-processing purposes). |

Remarks:

- Default Thickness.** Default values in place of zero shell thicknesses are taken from the cross-section property definition of the PID; see *SECTION_SHELL.
- Ordering.** Counterclockwise node numbering determines the top surface, see [Figure 17-25](#)
- Coordinate Systems.** Stresses and strain output in the binary databases are given in the global coordinate system, whereas stress resultants are output in the local coordinate system for the shell element.
- Convexity.** Interior angles must be less than 180 degrees.
- Material Orientation.** To allow the orientation of orthotropic and anisotropic materials to be defined for each shell element, a BETA angle can be defined. This BETA angle is used with the AOPT parameter and associated data on the *MAT card to determine an element reference direction for the element. The AOPT data defines a coordinate system and the BETA angle defines a subsequent rotation about the element normal to determine the element reference system. For composite modeling, each layer in the element can have a unique material direction by defining an additional rotation angle for the layer, using either the ICOMP and B_i parameters on *SECTION_SHELL or the B_i parameter

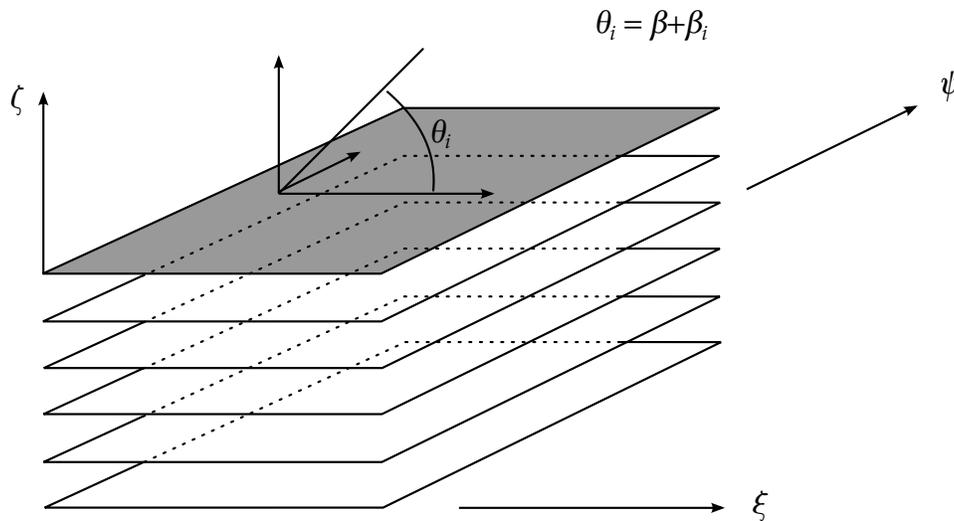

Figure 17-26. A multi-layer laminate can be defined. The angle β_i is defined for the i 'th lamina (integration point), see *SECTION_SHELL.

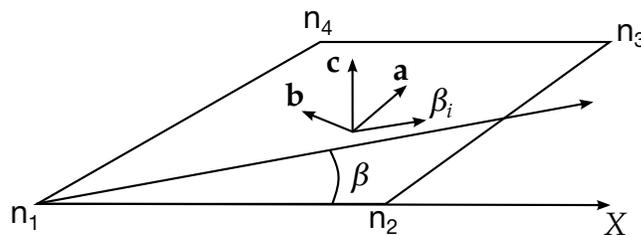

Figure 17-27. Orientation of material directions (shown relative to the 1-2 side as when AOPT = 0 in *MAT).

on *PART_COMPOSITE. The material direction for layer i is then determined by a rotation angle, θ_i as shown in [Figures 17-26](#) and [17-27](#).

6. **Activation of the BETA Field and Its Interpretation.** To activate the BETA field, either the BETA or THICKNESS keyword option must be used. There is a difference in how a zero value or empty field is interpreted. When the BETA keyword option is used, a zero value or empty BETA field will override the BETA on *MAT. However, when the THICKNESS keyword option is used, a zero value or empty BETA field will not override the BETA value on *MAT. Therefore, to input BETA = 0, the BETA keyword option is recommended. If a THIC value is omitted or input as zero, the thickness will default to the value on the *SECTION_SHELL card. If mid-side nodes are defined (N5 - N8), then a second line of thickness values will be read. This line may be left blank, but cannot be omitted.
7. **Offset for the Reference Surface.** The parameter OFFSET gives the offset from the nodal points of the shell to the reference surface. This option applies to most shell formulations excluding two-dimensional elements, membrane elements, and quadratic shell elements. Except for Mortar contacts, the refer-

ence surface offset given by OFFSET is not taken into account in the contact subroutines unless CNTCO is set to 1 in *CONTROL_SHELL. For Mortar contacts the OFFSET determines the location of the contact surface.

8. **Scalar Nodes.** The scalar nodes specified on the optional card refer to the scalar nodes defined by the user to hold additional degrees of freedom for shells with this capability. Scalar nodes are used with shell element type 25 and 26.
9. **Automatic Order Increase.** The option, SHL4_TO_SHL8, converts 3 node triangular and 4 node quadrilateral shell elements to 6 node triangular and 8 node quadrilateral quadratic shell elements, respectively, by the addition of mid-side nodal points. The user node ID's for these generated nodes are offset after the largest user node ID defined in the input file. When defining the *SECTION_SHELL keyword, the element type must be specified as either 23 or 24 corresponding to quadratic quadrilateral and triangular shells, respectively.
10. **Cohesive Elements.** Cohesive elements (ELFORM = 29, 46 or 47 on *SECTION_SHELL) may be defined with zero depth to connect surfaces with no gap between them, but must have nodes 1 and 2 on one surface and nodes 3 and 4 on the other.
11. **Contact Thickness when using *ELEMENT_SHELL_THICKNESS in MPP.** When using MPP, THEORY = 1 in *CONTROL_SHELL has special meaning when dealing with non-uniform-thickness shells, that is, it serves to set the nodal contact thickness equal to the average of the nodal thicknesses from the shells sharing that node. Thus when a contact surface is comprised of non-uniform-thickness shells, THEORY = 1 is recommended; the actual shell formulation can be set using ELFORM in *SECTION_SHELL.
12. **Assignment of Zero Thickness to Integration Points.** The ability to assign zero- thickness integration points in the stacking sequence allows the number of integration points to remain constant even as the number of physical plies varies from element to element and eases post-processing since a particular integration point corresponds to a physical ply. Such a capability is important when one or more of the physical plies are not continuous across a part. To represent a missing ply in *ELEMENT_SHELL_COMPOSITE, set THICK_i to 0.0 for the corresponding integration point and additionally, either set MID = -1 or, if the LONG option is used, set PLYID to any nonzero value

When postprocessing the results using LS-PrePost version 4.5, read both the keyword deck and d3plot database into the code and then select Option → N/A gray fringe. Then, when viewing fringe plots for a particular integration point (FriComp → IPt → intpt#), the element will be grayed out if the selected integration point is missing (or has zero thickness) in that element.

13. **PID with COMPOSITE keyword option.** When using the COMPOSITE keyword option, the PID on Card 1 must reference a *PART card that does not also use the COMPOSITE keyword option.

<BLANK>

TRIMMED

Available options for *OPTION2* include:

<BLANK>

TITLE

Purpose: Define a NURBS surface patch using two univariate knot vectors, a rectangular grid of control points, and optionally a set of control weights. The two knot vectors define the necessary shape functions and parameterize the surface by virtue of the tensor product scheme.

The *r*- and *s*-direction knot vectors have lengths of $NPR+PR+1$ and $NPS+PS+1$, respectively. NPR and NPS are the number of control points in each direction while PR and PS define the polynomial degree in each direction. The control grid consists of $NPR \times NPS$ control points. A control weight may be defined for each control point. There is no limit on the size of a NURBS surface patch.

The total number of necessary data cards depends on the parameters given in Cards 1 and 2, that is,

$$\# \text{ of cards} = 2 + \left\lceil \frac{NPR + PR + 1}{8} \right\rceil + \left\lceil \frac{NPS + PS + 1}{8} \right\rceil + (WFL + 1) \times NPS \times \left\lceil \frac{NPR}{8} \right\rceil ,$$

where $\lceil x \rceil = \text{ceil}(x)$. The flag WFL (see Card 2 below) indicates whether the control weights are user-defined. An example NURBS surface and the partial keyword deck using this keyword is given in [Figures 17-28](#) and [17-29](#), respectively.

A NURBS surface patch may be trimmed using the **TRIMMED** option. This requires the definition of additional trimming loop(s) which can be defined using Cards E and F. Note that optional cards used to define trimming loops are not counted in the above expression. See [Remark 6](#).

A description of the NURBS surface patch may be provided using the option **TITLE** which is also written to the `d3hsp` file.

Card Summary:

Card Title. This card is included if and only if the TITLE keyword option is used.

| Variable | C1 | C2 | C3 | C4 | C5 | C6 | C7 | C8 |
| Type | I | I | I | I | I | I | I | I |

VARIABLE**DESCRIPTION**

TITLE Title of the trimming loop

C_l Trimming curve ID pointing to a curve defined using *DEFINE_-NURBS_CURVE. A unique number has to be chosen.

Remarks:

1. **Shell Thickness.** The thickness of the shell is defined in *SECTION_SHELL and referenced via *PART.
2. **Element Formulation.** ELFORM=201 has to be used in *SECTION_SHELL.
3. **Rotational Degrees of Freedom.** FORM=4 allows the mixture of control points with and without rotational DOFs. This might be useful at the boundaries of NURBS patches where the continuity usually drops to C^0 and rotational DOFs are necessary. To indicate control points with rotational DOFs (6 DOFs/control point), the node number of the corresponding control point has to be set as the negative node ID in the connectivity Cards C. Positive node IDs indicate control points without rotational DOFs (3 DOFs/control point).

If FORM = -4 is used, the control points at the patch boundary are automatically treated with rotational DOFs without the need to specify them explicitly in the connectivity cards (Cards C). This might be sufficient in many cases.

4. **Interpolation Elements.** The post-processing and the treatment of contact boundary conditions are presently dealt with interpolation elements, defined via interpolation nodes. These nodes and elements are automatically created, see [Figure 17-29](#), where NISR and NISS indicate the number or average length of interpolation elements to be created per NURBS-element in the r- and s-directions, respectively.
5. **Periodic Patch.** A NURBS surface patch may be periodic in the parametric directions.
6. **Trimming Loops.** Trimmed NURBS surface elements / patches can be analyzed by defining trimming loops. A trimming loop is formed by a set of NURBS curves defined in the surface parametric coordinate system. Each trimming curve is defined using the *DEFINE_NURBS_CURVE keyword.

Trimming loops may be given a distinct title on Cards E and the connectivity of trimming curves defining a loop is stored on Cards F. The end and starting points of two consecutive curves *must* coincide. If the loop is defined by a single curve, the starting and end points of the curve *must* match. Furthermore, the orientation of the trimming loop is essential to define the trimmed surface. Travelling along the trimming loop, the surface on the right-hand side of the loop will be trimmed. There is no limitation on either the number of trimming curves forming a loop or the number of loops used to trim a NURBS surface element/patch.

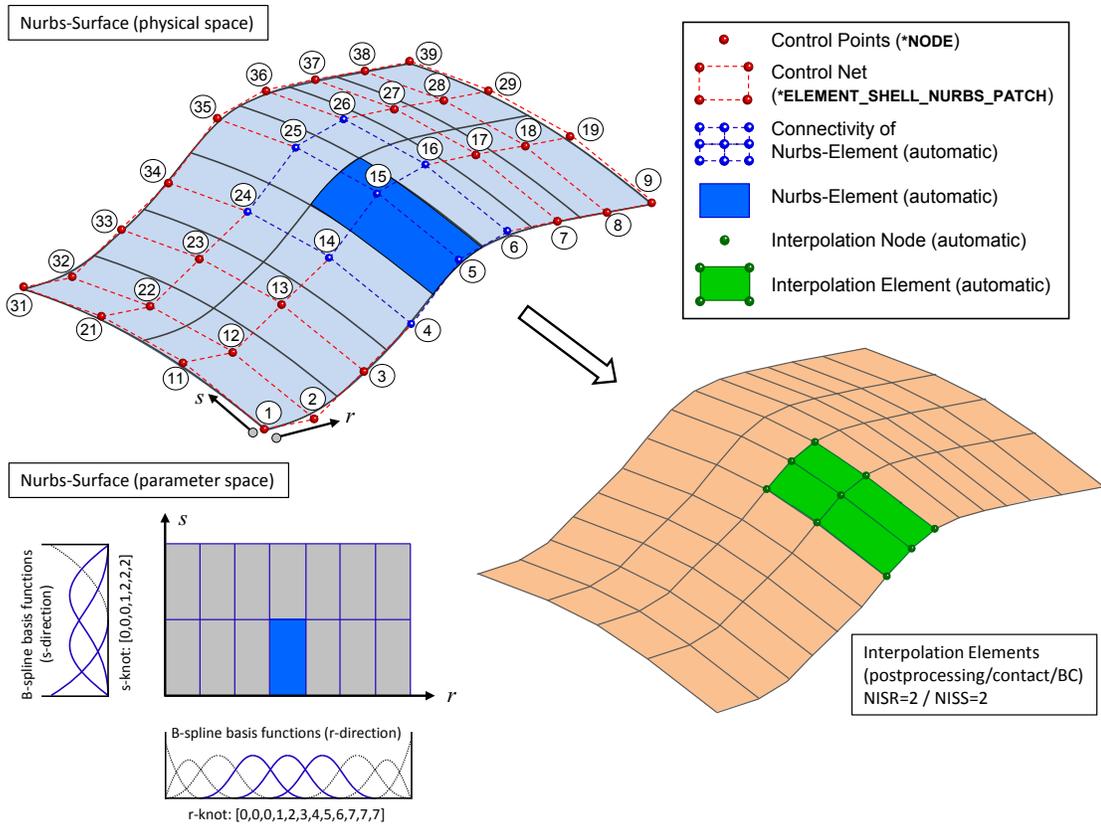

Figure 17-28. An example biquadratic NURBS surface patch and its interpolation mesh.

Figure 17-29. Excerpt of the *ELEMENT_SHELL_NURBS_PATCH keyword defining the biquadratic NURBS surface patch in [Figure 17-28](#).

***ELEMENT_SHELL_SOURCE_SINK**

Purpose: Define a strip of shell elements of a single part ID to simulate a continuous forming operation. This option requires logical regular meshing of rectangular elements, which implies that the number of nodal points across the strip is constant along the length. Elements are created at the source and disappear at the sink. The advantage of this approach is that it is not necessary to define an enormous number of elements to simulate a continuous forming operation. Currently, only one source-sink definition is allowed. The boundary conditions at the source are discrete nodal point forces to keep the work piece in tension. At the sink, displacement boundary conditions are applied.

T20

Purpose: Define three-dimensional solid elements. The type of solid element and its formulation is specified through the part ID (see *PART) and the section ID (see *SECTION_SOLID_OPTION). Also, a local coordinate system for orthotropic and anisotropic materials can be defined by using the ORTHO option. If extra degrees of freedom are needed, the DOF option should be used. The option TET4TOTET10 converts 4 node tetrahedrons to 10 node tetrahedrons, and H8TOH20/H8TOH27 converts 8-node hexahedrons to 20-node/27-node hexahedrons. The option H8TOH64 converts elements with linear basis functions to elements with cubic basis functions. See [Remark 1](#).

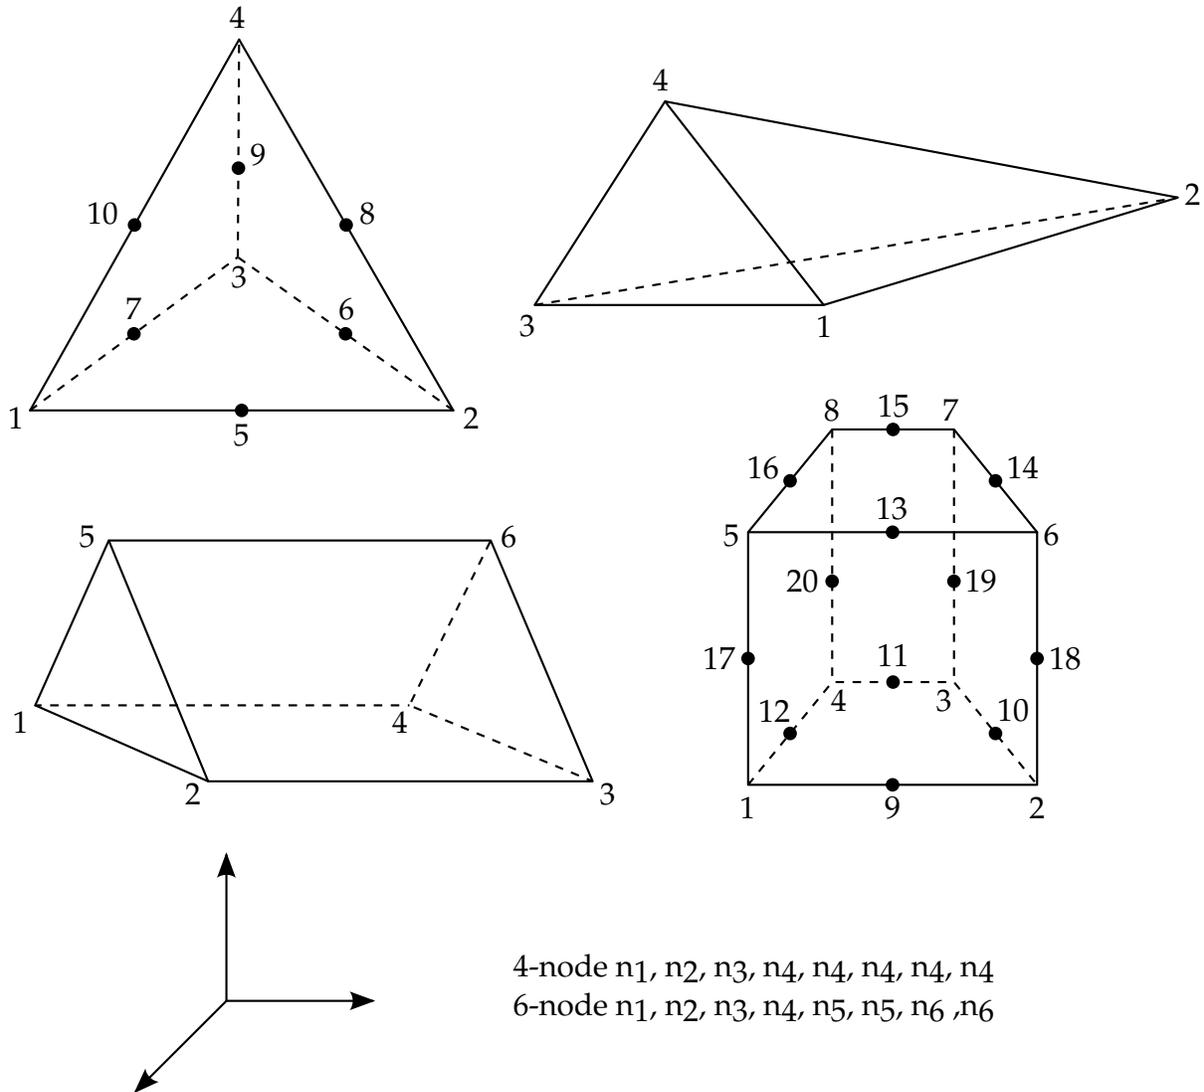

Figure 17-30. Four, six, eight, ten, and twenty node solid elements. For the hexahedral and pentahedral shapes, nodes 1-4 are on the bottom surface.

Remarks:

- Automatic Node Generation.** The option TET4TOTET10 automatically converts 4 node tetrahedral solids to 10 node quadratic tetrahedral solids. Additional mid-side nodes are created which are shared by all tetrahedral elements that contain the edge. The user node ID's for these generated nodes are offset after the largest user node ID defined in the input file. When defining the *SECTION_SOLID keyword, the element type must be specified as either 16 or 17 which are the 10-noded tetrahedrons in LS-DYNA. Mid-side nodes created as a result of TET4TOTET10 will not be automatically added to node sets that include the nodes of the original tetrahedron. So, for example, if the

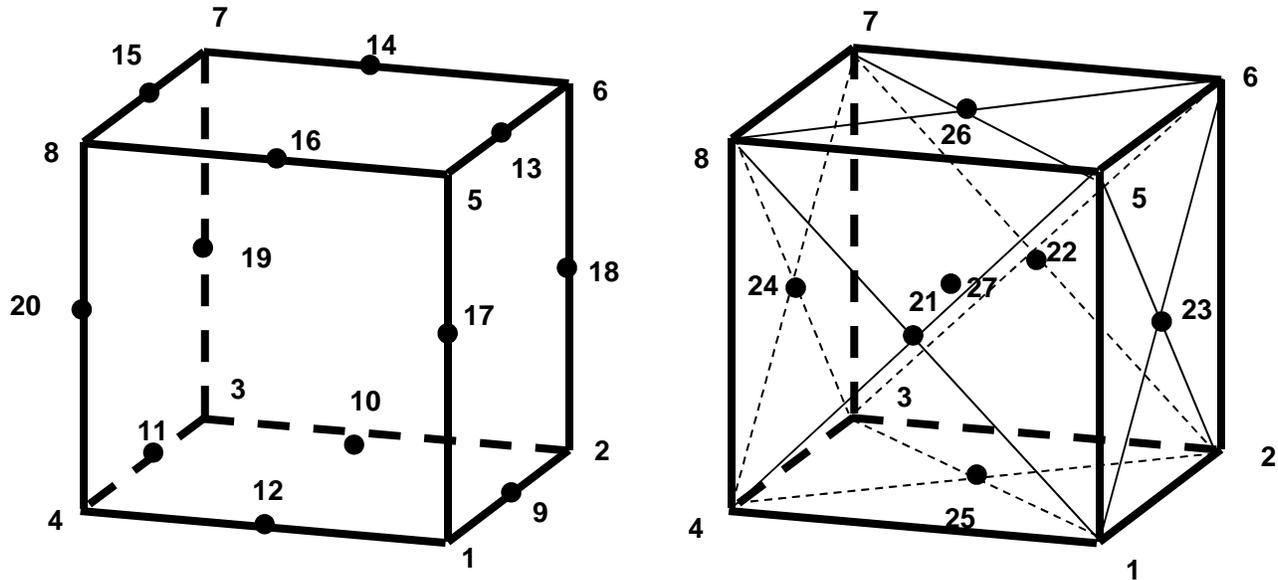

Figure 17-31. 27-node solid element.

tetrahedrons are to have an initial velocity, velocity initialization by part ID or part set ID using `*INITIAL_VELOCITY_GENERATION` is necessary as opposed to velocity initialization by node set ID using `*INITIAL_VELOCITY`. The option `H8TOH20/H8TOH27` provides the same functionality for converting 8-node to 20-node/27-node elements. The option `H8TOH64` converts 8-node to 64-node hexahedra, 4-noded to 20-node tetrahedra, and 6-noded to 40-node pentahedra. Mid-side nodes and face nodes created as a result of `H8TOH20/H8TO27/H8TO64` will automatically be added to node sets that include the nodes of the original hexahedron.

2. **Node Numbering.** Four, six, and eight node elements are shown in [Figure 17-30](#) where the ordering of the nodal points is shown. 27-node elements are shown in [Figure 17-31](#). This ordering must be followed or code termination will occur during the initialization phase with a negative volume message. The input of nodes on the element cards for the tetrahedral and pentahedral elements is given by:

4-noded tetrahedron N1, N2, N3, N4, N4, N4, N4, 0, 0

6-noded pentahedron N1, N2, N3, N4, N5, N5, N6, N6, 0, 0

To visualize the node numbering for higher order elements, that is, options `H27`, `H64`, `P21`, `P40`, `T15`, and `T20`, see [hexahedron 27](#), [hexahedron 64](#), [pentahedron 21](#), [pentahedron 40](#), [tetrahedron 15](#), and [tetrahedron 20](#).

3. **Degenerate Solids.** If hexahedrons are mixed with tetrahedrons and pentahedrons in the input under the same part ID, *degenerate* tetrahedrons and pentahedrons are used. One problem with degenerate elements is related to an

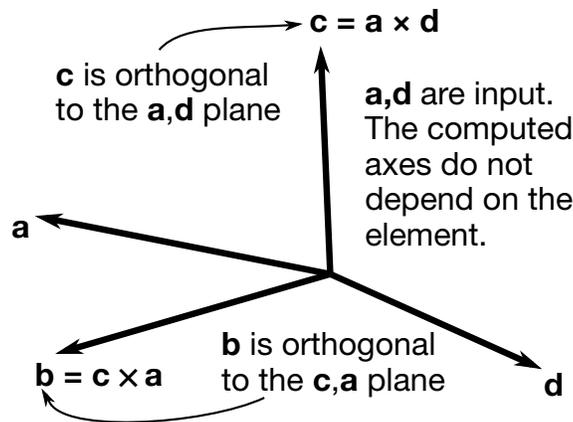

Figure 17-32. Two vectors a and d are defined and the triad is computed and stored.

uneven mass distribution (node 4 of the tetrahedron has five times the mass of nodes 1-3) which can make these elements somewhat unstable with the default time step size. By using the control flag under the keyword, `*CONTROL_SOLID`, automatic sorting can be invoked to treat the degenerate elements as type 10 and type 15 tetrahedral and pentahedral elements, respectively. The elements with cubic basis functions do not support degeneration.

- 4. Obsolete Card Format.** For elements with 4-8 nodes the cards in the format of LS-DYNA versions 940-970 are still supported. The older format does not include Card 2.

Obsolete Element Solid Card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|-----|-----|----|----|----|----|----|----|----|----|
| Variable | EID | PID | N1 | N2 | N3 | N4 | N5 | N6 | N7 | N8 |
| Type | I | I | I | I | I | I | I | I | I | I |

- 5. Local Directions.** For the orthotropic and anisotropic material models the local directions may be defined on the second card following the element connectivity definition. The local directions are then computed from the two vectors such that (see [Figure 17-32](#)):

$$c = a \times d \text{ and } b = c \times a.$$

These vectors are internally normalized within LS-DYNA. If the material model uses `AOPT = 3`, the a and b -axes will be rotated about the c -axis by the `BETA` angle on the material card.

- 6. Stress Output Coordinates.** Stress output for solid elements is in the global coordinate system by default.

7. **Interpretation of A1 Field.** If vector **d** is input as a zero length vector, then A1 is interpreted as an offset rotation angle BETA in degrees which describes a rotation about the **c**-axis of the **a-b-c** coordinate system that is defined by AOPT and associated parameters on the *MAT input. This BETA angle applies to all values of AOPT, and it overrides the BETA angle on the *MAT card in the case of AOPT = 3.
8. **Optional “Scalar” Nodes.** The scalar nodes specified on the optional card refer to extra nodes used by certain features (usual user defined) to store additional degrees of freedom.

***ELEMENT_SOLID_NURBS_PATCH**

Purpose: Define a NURBS-block element (patch) based on a cuboid grid of control points. This grid consists of $NPR \times NPS \times NPT$ control points, where NPR, NPS and NPT are the number of control points in local r -, s - and t -directions, respectively. The necessary shape functions are defined through three knot-vectors:

1. Knot-Vector in r -direction with length $NPR + PR + 1$
2. Knot-Vector in s -direction with length $NPS + PS + 1$
3. Knot-Vector in t -direction with length $NPT + PT + 1$

There is no limit on the size of the underlying grid to define a NURBS-block element, so the total number of necessary cards depends on the parameters given in the first two cards and is given by

$$\# \text{ of cards} = 2 + \left\lceil \frac{NPR + PR + 1}{8} \right\rceil + \left\lceil \frac{NPS + PS + 1}{8} \right\rceil + \left\lceil \frac{NPT + PT + 1}{8} \right\rceil + NPR \times NPS \times NPT$$

where $\lceil x \rceil = \text{ceil}(x)$. (NOTE: the last term in the sum is doubled if $WFL = 1$, indicating that the weights are user-specified).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | NPID | PID | NPR | PR | NPS | PS | NPT | PT |
| Type | I | I | I | I | I | I | I | I |
| Default | none |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|------|------|------|-------|------|---|-------|
| Variable | WFL | NISR | NISS | NIST | IMASS | IINT | | IDFNE |

| Type | I | I | I | I | I | I | I | I |
| Default | none |

Weight cards. Additional card for $WFL \neq 0$. Set a weight for each control point. These cards have an ordering identical to the Connectivity Cards (Card 6).

| Card 7 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | W1 | W2 | W3 | W4 | W5 | W6 | W7 | W8 |
| Type | F | F | F | F | F | F | F | F |
| Default | none |

VARIABLE**DESCRIPTION**

| | |
|------|--|
| NPID | NURBS-Patch Element ID. A unique number has to be chosen |
| PID | Part ID, see *PART. |
| NPR | Number of control points in local r -direction. |
| PR | Order of polynomial of univariate NURBS basis functions in local r -direction. |
| NPS | Number of control points in local s -direction. |
| PS | Order of polynomial of univariate NURBS basis functions in local s -direction. |
| NPT | Number of control points in local t -direction. |

| | |
|------------------------|---|
| PT | Order of polynomial of univariate NURBS basis functions in local t -direction. |
| WFL | Flag for weighting factors of the control points EQ.0: all weights at the control points are set to 1.0 (B-spline basis) and no optional Card 7 sets are allowed NE.0: the weights at the control points are defined with optional Card 7 which must be defined after sets of Card 6. |
| NISR | Number of (automatically created) Interpolation Solid elements in local r -direction per created NURBS-element for visualization (post-processing) and contact. |
| NISS | Number of (automatically created) Interpolation Solid elements in local s -direction per created NURBS-element for visualization (post-processing) and contact. |
| NIST | Number of (automatically created) Interpolation Solid elements in local t -direction per created NURBS-element for visualization (postprocessing) and contact. |
| IMASS | Option for lumping of mass matrix: EQ.0: row sum EQ.1: diagonal weighting. |
| IINT | Numerical integration rule: EQ.0: Reduced Gauss integration. $NIP = PR \times PS \times PT$. EQ.1: Full Gauss integration. $NIP = (PR+1) \times (PS+1) \times (PT+1)$. |
| IDFNE | Element ID of first NURBS-Element within this NURBS-Patch definition. |
| RK _{<i>i</i>} | Values of the univariate knot vector in local r -direction defined in Card 3. |
| SK _{<i>i</i>} | Values of the univariate knot vector in local s -direction defined in Card 4. |
| TK _{<i>i</i>} | Values of the univariate knot vector in local t -direction defined in Card 5. |
| N _{<i>i</i>} | Control points i (defined via *NODE) to define the control grid in Card 6. |

W_i Weighting factors of the control point i defined in Card 7.

Remarks:

1. **ELFORM.** ELFORM = 201 has to be used in *SECTION_SOLID.
2. **Interpolation Elements.** The post-processing and the treatment of contact boundary conditions are presently dealt with using interpolation elements, defined via interpolation nodes. These nodes and elements are automatically created, where NISR, NISS and NIST indicate the number of interpolation elements to be created per NURBS-element in the local r -, s - and t -direction, respectively.

*ELEMENT_SPH_{OPTION}

Available options include:

<BLANK>

VOLUME

Purpose: Define a lumped mass element assigned to a nodal point.

If the VOLUME option is used, the field for MASS of the following cards is treated as particle volume. It has the same effect as giving a negative number in each field.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|------|------|------|---|---|---|---|---|---|----|
| Variable | NID | PID | MASS | | | | | | | |
| Type | I | I | F | | | | | | | |
| Default | none | none | 0. | | | | | | | |
| Remarks | | | 1 | | | | | | | |

| VARIABLE | DESCRIPTION |
|----------|---|
| NID | Node ID and Element ID are the same for the SPH option. |
| PID | Part ID to which this node (element) belongs. |
| MASS | GT.0: Mass value LT.0: Volume. The absolute value will be used as volume. The density ρ will be retrieved from the material card defined in PID. SPH element mass is calculated by $ MASS \times \rho$. |

Remarks:

- Axisymmetric SPH.** Axisymmetric SPH (IDIM = -2 in *CONTROL_SPH) is defined on the global XY-plane, with Y-axis as the axis of rotation. An axisymmetric SPH element has a mass of ρA , where ρ is its density and A is the area of the SPH element. A can be approximated by the area of its corresponding axisymmetric shell element (see Figure 17-33). The mass printout in the d3hsp file is the mass per radian, that is, $\rho A x_i$. See Figure 17-34.

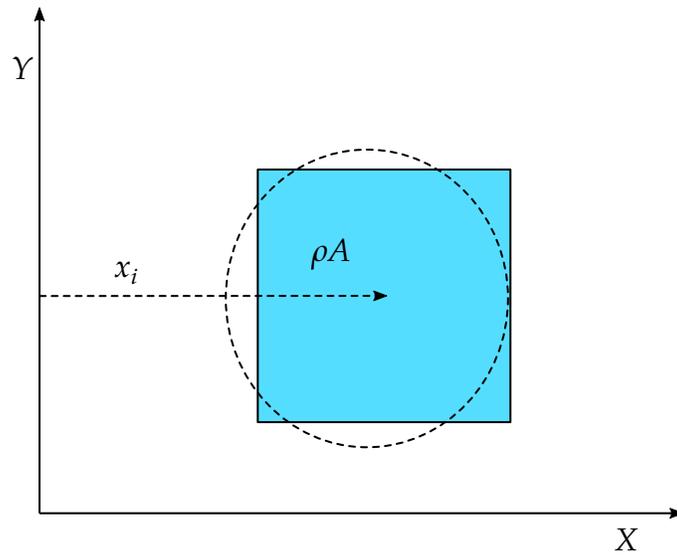

Figure 17-33. Schematic of axisymmetric SPH cross section

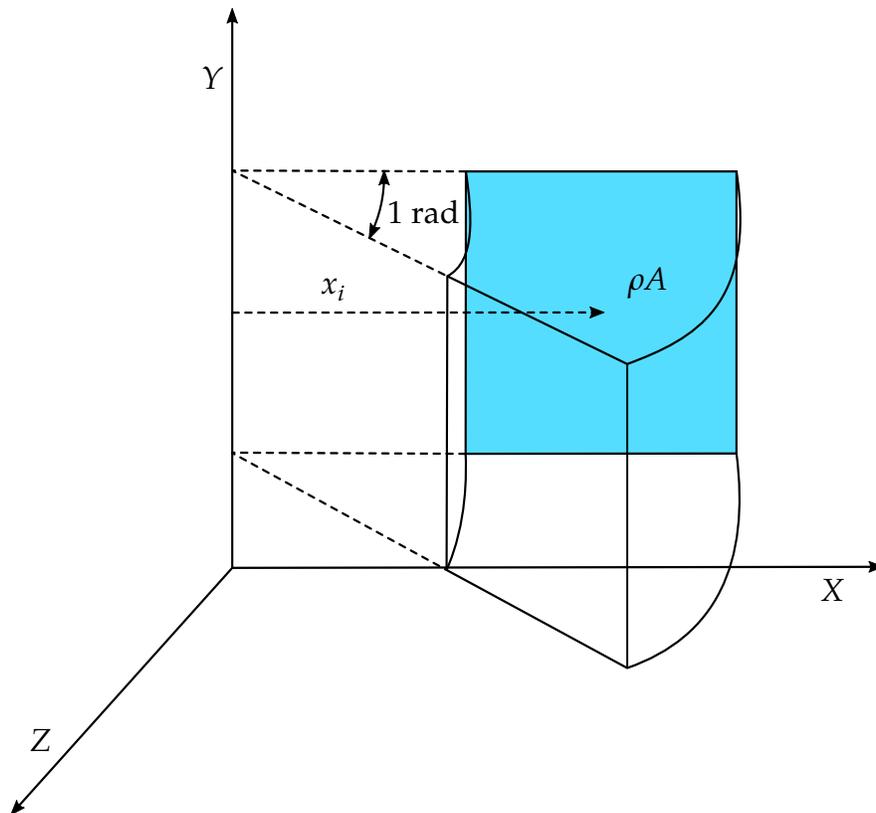

Figure 17-34. Mass printout in d3hsp

NOTE: This keyword was replaced by *CONTROL_FORMING_TRIMMING starting in Revision 87566.

***ELEMENT_TSHHELL_{OPTION}**

Available options include:

<BLANK>

BETA

COMPOSITE

Purpose: Define an eight node thick shell element which is available with either fully reduced or selectively reduced integration rules. Thick shell formulations 1, 2, and 6 are plane stress elements that can be used as an alternative to the 4 node shell elements in cases where an 8-node element is desired. Thick shell formulations 3, 5 and 7 are layered solids with 3D stress updates. Formulation 5, 6, and 7 are based on an enhanced strain. The number of through-thickness integration points is specified by the user.

For orthotropic and anisotropic materials, a local material angle (variable BETA) can be defined which is cumulative with the integration point angles specified in *SECTION_TSHHELL or *PART_COMPOSITE_TSHHELL.

The COMPOSITE option for *ELEMENT_TSHHELL allows a unique stackup of integration points for each element sharing the same part ID, and is available only when combined with *PART. The COMPOSITE option is not available in combination with *PART_COMPOSITE_TSHHELL. To maintain a direct association of through-thickness integration point numbers with physical plies in the case where the number of plies varies from element to element, see [Remark 5](#).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |

| Type | I | I | I | I | I | I | I | I | I | I |
| Default | none |
| Remarks | | | 1 | | | | | | | |

Beta Card. Additional card for BETA keyword option.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|---|---|---|---|---|---|---|---|------|----|
| Variable | | | | | | | | | BETA | |
| Type | | | | | | | | | F | |
| Default | | | | | | | | | 0. | |
| Remarks | | | | | | | | | 4 | |

Composite Cards. Additional card for COMPOSITE keyword option. Values of material ID, thickness, and material angle for each through-thickness integration point of a composite shell are defined using these cards, and these values overrule values specified elsewhere. The integration point data should be given sequentially starting with the bottommost integration point. The total number of integration points is determined by the number of entries on these cards. The total thickness is the distance between the top and bottom surface as determined by the element connectivity, so the THICK i values are scaled to fit the element. Define as many cards as needed. The input ends at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|----|---|------|--------|----|---|
| Variable | MID1 | THICK1 | B1 | | MID2 | THICK2 | B2 | |
| Type | I | F | F | | I | F | F | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|----|---|------|---|---|---|
| Variable | MID3 | THICK3 | B3 | | Etc. | | | |
| Type | I | F | F | | I | F | F | |

VARIABLE**DESCRIPTION**

EID Element ID. Unique numbers have to be used.

PID Part ID, see *PART.

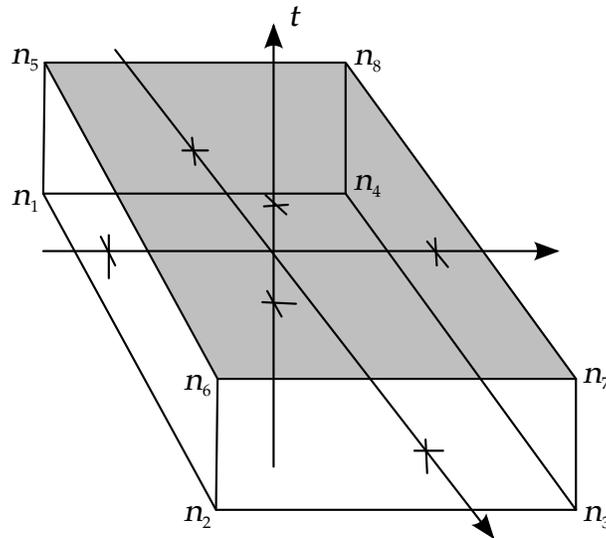

Figure 17-35. 8-node Thick Shell Element.

| VARIABLE | DESCRIPTION |
|-----------|---|
| N1 | Nodal point 1 |
| N2 | Nodal point 2 |
| N3 | Nodal point 3 |
| ⋮ | ⋮ |
| N8 | Nodal point 8 |
| BETA | Orthotropic material base offset angle (see Remark 4). The angle is given in degrees. If blank the default is set to zero. |
| MID i | Material ID of integration point i , see the *MAT_... cards. |
| THICK i | Thickness of integration point i |
| B i | Material angle of integration point i |

Remarks:

1. **Orientation.** Extreme care must be used in defining the connectivity to ensure proper orientation of the through-thickness direction. For a hexahedron, nodes n_1 to n_4 define the lower surface, and nodes n_5 to n_8 define the upper surface. For a pentahedron, nodes n_1, n_2, n_3 form the lower triangular surface and the eight variables N1 to N8 should be defined using nodes $n_1, n_2, n_3, n_3, n_4, n_5, n_6, n_6$, respectively. Note that node n_3 and node n_6 are each repeated.

2. **Integration.** Element formulations 1 and 5 (see *SECTION_TSHELL), use one point integration and the integration points then lie along the t -axis as shown in Figure 17-35. Element formulations 2 and 3 use two by two selective reduced integration in each layer.
3. **Stress Output.** The stresses for thick shell elements are output in the global coordinate system.
4. **Local Coordinate System.** To allow the orientation of orthotropic and anisotropic materials to be defined for each thick shell element, a beta angle can be defined. This beta angle is used with the AOPT parameter and associated data on the *MAT card to determine an element reference direction for the element.

The AOPT data defines a coordinate system and the BETA angle defines a subsequent rotation about the element normal to determine the element reference system. For composite modeling, each layer in the element can have a unique material direction by defining an additional rotation angle for the layer, using either the ICOMP and B_i fields on *SECTION_TSHELL or the B_i parameter on *PART_COMPOSITE_TSHELL. The material direction for layer i is then determined by a rotation angle, θ_i .

5. **Assignment of Zero Thickness to Integration Points.** The ability to assign zero-thickness integration points in the stacking sequence allows the number of integration points to remain constant even as the number of physical plies varies from element to element and eases post-processing since a particular integration point corresponds to a physical ply. Such a capability is important when one or more of the physical plies are not continuous across a part. To represent a missing ply in *ELEMENT_TSHELL_COMPOSITE, set THICK i to 0.0 for the corresponding integration point and additionally, set MID to -1.

When post-processing the results using LS-PrePost version 4.5, read both the keyword deck and d3plot database into the code and then select Option→N/A gray fringe. Then, when viewing fringe plots for a particular integration point (FriComp→IP t →intpt#), the element will be grayed out if the selected integration point is missing (or has zero thickness) in that element.

6. **PID with COMPOSITE keyword option.** When using the COMPOSITE keyword option, the PID on Card 1 must reference a *PART card that does not also use the COMPOSITE keyword option.

***END**

The *END command is optional and signals the conclusion of a keyword input file. Data in a keyword file beyond a *END command are not read by LS-DYNA.

***EOS**

Please see LS-DYNA Keyword User's Manual, Volume II (Material Models).

***FATIGUE**

***FATIGUE**

Purpose: The keyword *FATIGUE provides a way of defining and solving fatigue and durability analysis problems. The keyword cards in this section are defined in alphabetical order:

*FATIGUE_{*OPTION*}

*FATIGUE_MEAN_STRESS_CORRECTION

***FATIGUE_{OPTION}**

Available options include:

<BLANK>

ELOUT

Purpose: Perform fatigue analysis on parts or structures to get cumulative damage ratio and expected fatigue life.

Cards 1 and 2 are not needed when the option ELOUT is used.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|---|---|---|---|---|---|
| Variable | PID | PTYPE | | | | | | |
| Type | I | I | | | | | | |
| Default | none | 0 | | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | DT | | | | | | | |
| Type | F | | | | | | | |
| Default | none | | | | | | | |

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|--------|---|---|---|---|---|
| Variable | STRSN | INDEX | RESTRT | | | | | |
| Type | I | I | I | | | | | |
| Default | 0 | 0 | 0 | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| PID | Part ID, Part Set ID, or Element (solid, shell, beam, thick shell) Set ID. If SSID = 0, then the fatigue analysis is performed on the whole structure. |
| PTYPE | Type of PID: EQ.0: Part (default) EQ.1: Part set EQ.2: SET_SOLID EQ.3: SET_BEAM EQ.4: SET_SHELL EQ.5: SET_TSHELL |
| DT | Time step for saving the stress/strain data in transient analysis. |
| STRSN | Type of fatigue analysis variable: EQ.0: Stress (default)S EQ.1: Strain |
| INDEX | Stress/strain index for performing fatigue analysis: EQ.0: Von-Mises stress/strain EQ.1: Maximum principal stress/strain EQ.2: Maximum shear stress/strain |
| RESTR | Restart options. This flag is used to save an LS-DYNA transient analysis if the binary database for stress/strain time history data has been created in last runs. EQ.0: initial run EQ.1: restart with existing stress/strain binary database |

Remarks:

1. When ELOUT is used, the stress/strain data are provided by ELOUT database. User need to define the keyword *DATABASE_ELOUT to define the time step for writing the stress/strain data. In addition, user need to set BINARY = 2 in *DATABASE_ELOUT so that the data is written to a binary database "binout"; User also need to use the keywords *DATABASE_HISTORY_SOLID, or *DATABASE_HISTORY_SHELL, or *DATABASE_HISTORY_TSHELL, or

*DATABASE_HISTORY_BEAM to define the elements where the stress/strain data are needed and the fatigue analysis is requested.

2. Currently, the fatigue analysis is performed based on ELOUT database. Thus, the option ELOUT is always needed.
3. When RESTRT = 1, LS-DYNA reads the existing binary database (by default, binout) to get the stress/strain time history data, to run fatigue analysis. This binary database should be in the same directory as the current run.
4. The results (fatigue life, accumulative damage ratio, etc.) are saved in binary plot database d3ftg.

*FATIGUE

*FATIGUE_MEAN_STRESS_CORRECTION

*FATIGUE_MEAN_STRESS_CORRECTION

Purpose: Define mean stress correction method for fatigue analysis.

Cards 1 and 2 are not needed when the option ELOUT is used.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|---|---|---|---|---|---|---|
| Variable | METHOD | | | | | | | |
| Type | I | | | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|---|---|---|---|---|---|
| Variable | MID | SIGMA | | | | | | |
| Type | I | F | | | | | | |
| Default | none | none | | | | | | |

VARIABLE

DESCRIPTION

METHOD

Mean stress correction method:

EQ.0: Goodman equation

EQ.1: Soderberg equation

EQ.2: Gerber equation

EQ.3: Goodman tension only

EQ.4: Gerber tension only

EQ.11: Morrow equation

EQ.12: Smith-Watson-Topper equation

MID

Material ID for which the current mean stress correction method is applied.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| SIGMA | Ultimate tensile strength σ_u to be used in Goodman equation (METHOD = 0, 3), or Gerber equation (METHOD = 2, 4); or yield strength σ_y to be used in Soderberg equation (METHOD = 1) |

Remarks:

1. This keyword can be applied in both time domain and frequency domain fatigue analysis. The method options (METHOD = 0, 1, 2, 3, 4) are used for stress-based fatigue analysis; The method options (METHOD = 11, 12) are used for strain-based fatigue analysis.
2. Card 2 can be repeated if there are multiple material models in the input deck and they have different SIGMA values.

***FREQUENCY_DOMAIN**

Purpose: The keyword *FREQUENCY_DOMAIN provides a way of defining and solving frequency domain vibration and acoustic problems. The keyword cards in this section are defined in alphabetical order:

- *FREQUENCY_DOMAIN_ACCELERATION_UNIT
- *FREQUENCY_DOMAIN_ACOUSTIC_BEM_{OPTION}
- *FREQUENCY_DOMAIN_ACOUSTIC_FEM
- *FREQUENCY_DOMAIN_ACOUSTIC_FRINGE_PLOT_{OPTION}
- *FREQUENCY_DOMAIN_ACOUSTIC_INCIDENT_WAVE
- *FREQUENCY_DOMAIN_ACOUSTIC_SOUND_SPEED
- *FREQUENCY_DOMAIN_FRF
- *FREQUENCY_DOMAIN_MODE_{OPTION}
- *FREQUENCY_DOMAIN_PATH
- *FREQUENCY_DOMAIN_RANDOM_VIBRATION_{OPTION}
- *FREQUENCY_DOMAIN_RESPONSE_SPECTRUM
- *FREQUENCY_DOMAIN_SSD

***FREQUENCY_DOMAIN*FREQUENCY_DOMAIN_ACCELERATION_UNIT**

***FREQUENCY_DOMAIN_ACCELERATION_UNIT**

Purpose: LS-DYNA's default behavior is to *assume* that accelerations are derived:

$$[\text{acceleration unit}] = \frac{[\text{length unit}]}{[\text{time unit}]^2}.$$

This card extends LS-DYNA to support *other* units for acceleration.

| | | | | | | | | |
|----------|------|------|--|--|--|--|--|--|
| Card 1 | 1 | 2 | | | | | | |
| Variable | UNIT | UMLT | | | | | | |
| Type | I | F | | | | | | |

VARIABLE

DESCRIPTION

UNIT

Flag for acceleration unit conversion:

EQ.0: use $[\text{length unit}]/[\text{time unit}]^2$ as unit of acceleration.

EQ.1: use g as unit for acceleration, and SI units (Newton, kg, meter, second, etc.) elsewhere.

EQ.2: use g as unit for acceleration, and Engineering units (lbf, $\text{lbf} \times \text{second}^2/\text{inch}$, inch, second, etc.) elsewhere.

EQ.3: use g as unit for acceleration, and units (kN, kg, mm, ms, GPa, etc.) elsewhere.

EQ.-1: use g as unit for acceleration and provide the multiplier for converting g to $[\text{length unit}]/[\text{time unit}]^2$.

UMLT

Multiplier for converting g to $[\text{length unit}]/[\text{time unit}]^2$ (used only for UNIT = -1).

Remarks:

LS-DYNA uses consistent units. With *consistent units* acceleration is defined using:

$$[\text{acceleration unit}] = \frac{[\text{length unit}]}{[\text{time unit}]^2}.$$

However, it is the convention of many industries to use g (gravitational acceleration on the Earth's surface) as the base unit for acceleration. Usually, data from vibration tests, both random and sine sweep, are expressed in systems for which g is the unit of acceleration. With this keyword, LS-DYNA supports such conventions. Internally, LS-DYNA implements this keyword by converting the input deck into consistent units, and

***FREQUENCY_DOMAIN_ACCELERATION_UNIT*FREQUENCY_DOMAIN**

then proceeding with the calculation as usual. However, results are output in the unit system specified with this keyword.

*FREQUENCY_DOMAIN

*FREQUENCY_DOMAIN_ACOUSTIC_BEM

*FREQUENCY_DOMAIN_ACOUSTIC_BEM_{OPTION1}_{OPTION2}

Available options include:

<BLANK>

ATV

MATV

HALF_SPACE

PANEL_CONTRIBUTION

Purpose: Activate the boundary element method in frequency domain for acoustic problems. This keyword is ignored unless the **BEM=filename** option is included in the LS-DYNA command line:

| Variable | T_HOLD | DECAY | | | | | | |
| Type | F | F | | | | | | |
| Default | 0.0 | 0.02 | | | | | | |

VARIABLE

DESCRIPTION

T_HOLD Hold-off period before the exponential window. The length of the hold-off period should coincide with the pre-trigger time to reduce the effects of noise in the captured time domain data. It is only used when FFTWIN = 5.

DECAY Decay ratio at the end of capture duration. For example, if the DECAY = 0.02, it means that the vibration is forced to decay to 2% of its amplitude within the capture duration. This field is only used when FFTWIN = 5.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

VARIABLE

DESCRIPTION

METHOD Method used in acoustic analysis:
EQ.0: Rayleigh method (very fast).
EQ.1: Kirchhoff method coupled to FEM for acoustics (*MAT_ACOUSTIC). See [Remark 6](#).
EQ.2: Variational Indirect BEM.

| VARIABLE | DESCRIPTION |
|----------|---|
| | EQ.3: collocation BEM. |
| | EQ.4: collocation BEM with Burton-Miller formulation for exterior problems (no irregular frequency phenomenon). |
| MAXIT | Maximum number of iterations for iterative solver (default = 100) if METHOD ≥ 2. |
| TOLITR | Tolerance for the iterative solver. The default value is 10 ⁻⁴ . |
| NDD | Number of domain decompositions, used for memory saving. For large problems, the boundary mesh is decomposed into NDD domains for less memory allocation. This option is only used if METHOD ≥ 2. |
| TOLLR | Tolerance for low rank approximation of dense matrix (default = 10 ⁻⁶). |
| TOLFCT | Tolerance in factorization of the low rank matrix (default = 10 ⁻⁶). |
| IBDIM | Inner iteration limit in GMRES iterative solver (default = 1000). |
| NPG | Number of Gauss integration points (default = 2). |

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---|-----|--------|-------|------|-------|--------|-----|
| Variable | | NBC | RESTRT | IEDGE | NOEL | NFRUP | VELOUT | DBA |
| Type | | I | I | I | I | I | I | I |
| Default | | 1 | 0 | 0 | 0 | 0 | 0 | 0 |
| Remark | | | 8 | 9 | 10 | 11 | | |

| VARIABLE | DESCRIPTION |
|----------|---|
| NBC | Number of boundary condition cards. See Card 4.1 (default = 1). |
| RESTRT | This flag is used to save an LS-DYNA analysis if the binary output file in the (bem= filename) option has not been changed (default = 0). |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | EQ.0: LS-DYNA time domain analysis is processed and generates a new binary file. |
| | EQ.1: LS-DYNA time domain analysis is not processed. The binary files from previous run are used. The files include the binary output file <code>filename</code> and the binary file <code>bin_velfreq</code> , which saves the boundary velocity from FFT. |
| | EQ.2: LS-DYNA restarts from <code>d3dump</code> file by using “R=” command line parameter. This is useful when the last run was interrupted by sense switches such as “sw1”. |
| | EQ.3: LS-DYNA reads in user provided velocity history saved in an ASCII file, <code>bevel</code> . |
| | EQ.4: run acoustic computation on a boundary element mesh with velocity information given with a denser finite element mesh in last run. This option requires both “ <code>bem = filename</code> ” and “ <code>lbem = filename2</code> ” in the command line, where <code>filename2</code> is the name of the binary file generated in the last run with denser mesh. |
| | EQ.5: LS-DYNA time domain analysis is not processed. The binary file <code>filename</code> from previous run is used. An FFT is performed to get the new frequency domain boundary velocity and the results are saved in <code>bin_velfreq</code> . |
| IEDGE | Free edge and multi-connection constraints option (default = 0). EQ.0: free edge and multi-connection constraints not considered. EQ.1: free edge and multi-connection constraints considered. EQ.2: only free edge constraints are considered. EQ.3: only multi-connection constraints are considered. |
| NOEL | Location where normal velocity or acceleration is taken (default = 0). EQ.0: elements or segments. EQ.1: nodes. |
| NFRUP | Preconditioner update option. EQ.0: updated at every frequency. GE.1: updated for every NFRUP frequencies. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| VELOUT | Flag for writing out nodal or elemental velocity data. EQ.0: no writing out velocity data. EQ.1: write out time domain velocity data (in x , y and z directions). EQ.2: write out frequency domain velocity data (in normal direction). |
| DBA | Flag for writing out weighted SPL files with different weighting options. EQ.0: no writing out weighted SPL files. EQ.1: write out Press_dB(A) by using A-weighting. EQ.2: write out Press_dB(B) by using B-weighting. EQ.3: write out Press_dB(C) by using C-weighting. EQ.4: write out Press_dB(D) by using D-weighting. |

Boundary Condition Cards. The deck must include NBC cards in this format: one for each boundary condition.

| Card 4.1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|------|--------|-----|-----|---|---|
| Variable | SSID | SSTYPE | NORM | BEMTYP | LC1 | LC2 | | |
| Type | I | I | I | I | I | I | | |
| Default | 0 | 0 | 0 | 0 | 0 | 0 | | |
| Remark | 12 | | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| SSID | Part, part set ID, or segment set ID of boundary elements. |
| SSTYPE | Boundary element type: EQ.0: part set ID EQ.1: part ID EQ.2: segment set ID. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| NORM | <p>NORM should be set such that the normal vectors point away from the fluid.</p> <p>EQ.0: normal vectors are not inverted (default).</p> <p>EQ.1: normal vectors are inverted.</p> |
| BEMTYP | <p>Type of input boundary values in BEM analysis.</p> <p>EQ.0: boundary velocity will be processed in BEM analysis.</p> <p>EQ.1: boundary acceleration will be processed in BEM analysis.</p> <p>EQ.2: pressure is prescribed, and the real and imaginary parts are given by LC1 and LC2.</p> <p>EQ.3: normal velocity is prescribed, and the real and imaginary parts are given by LC1 and LC2.</p> <p>EQ.4: impedance is prescribed, and the real and imaginary parts are given by LC1 and LC2.</p> <p>LT.0: normal velocity (only real part) is prescribed through amplitude as a function of frequency load curve with curve ID BEMTYP .</p> |
| LC1 | Load curve ID for defining real part of pressure, normal velocity or impedance. |
| LC2 | Load curve ID for defining imaginary part of pressure, normal velocity or impedance. |

Panel Contribution Card. Additional for PANEL_CONTRIBUTION keyword option.

| Card 5 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|---|---|---|---|---|---|---|
| Variable | NSIDPC | | | | | | | |
| Type | I | | | | | | | |
| Default | 0 | | | | | | | |
| Remark | 13 | | | | | | | |

| VARIABLE | DESCRIPTION |
|----------|---|
| NSIDPC | Node set ID for the field points where panel contributions to SPL (Sound Pressure Level) are requested. |

Half Space Card. Additional card for HALF_SPACE keyword option.

| Card 6 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|---|---|---|---|---|---|---|
| Variable | PID | | | | | | | |
| Type | I | | | | | | | |
| Default | 0 | | | | | | | |

| VARIABLE | DESCRIPTION |
|----------|--|
| PID | Plane ID for defining the half-space problem; see keyword *DEFINE_PLANE. |

Remarks:

1. **TSART Field.** TSTART indicates the time at which velocity or acceleration and pressure are stored in the binary file.
2. **PREF Field.** This reference pressure is required for the computation of the pressure in dB. Usually, in International Unit System the reference pressure is 20 μ Pa.
3. **FFT Windowing.** Velocity or acceleration (pressure) is provided by LS-DYNA analysis. They are written in a binary file (**bem=filename**). The boundary element method is processed after the LS-DYNA analysis. An FFT algorithm is used to transform time domain data into frequency domain in order to use the boundary element method for acoustics. To overcome the FFT leakage problem due to the truncation of the temporal response, several windows are proposed. Windowing is used to have a periodic velocity, acceleration and pressure in order to use the FFT.
4. **TRSLT Field.** If time domain results are requested, FMIN is changed to 0.0 in the code.
5. **IUNITS Field.** Units are automatically converted into kg, m, s, N, and Pa so that the reference pressure will not be too small. For example, it may be as low

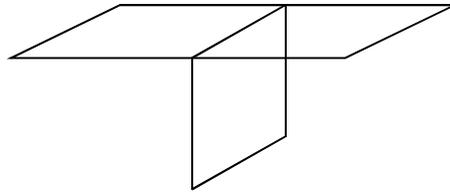

Figure 21-1. T-section.

as 20.E-15 GPa if one uses the units kg, mm, ms, kN, and GPa, and this may result in truncation error in the computation, especially in single precision version.

6. **METHOD Field.** The Rayleigh method is an approximation suitable only for external radiation problems. It is very fast since there is no linear system to solve. The Kirchhoff method involves coupling the BEM and FEM for acoustics (*MAT_ACOUSTIC) with a non-reflecting boundary condition; see *BOUNDARY_NON_REFLECTING. In this case, at least one fluid layer with a non-reflecting boundary condition is merged with the vibrating structure. This additional fluid is given in *MAT_ACOUSTIC by the same density and sound speed as used in this keyword. When used appropriately, both methods provide a good approximation to a full BEM calculation for external problems.
7. **NDD Field.** The BEM formulation for large and medium size problems (more than 2000 boundary elements) is memory and time consuming. In this case, LS-DYNA may be run using the memory option. To save memory, domain decomposition can be used.
8. **RESTRT Field.** The binary file generated by a previous run can be used for the next run by using the restart option. With the restart option the BEM calculation uses the binary file generated from a previous calculation. In this case, the frequency range can be changed. However, the time parameters should not be modified between calculations.
9. **IEDGE Field.** This field only applies to METHOD = 2, the Variational Indirect BEM.
10. **NOEL Field.** This field specifies whether the element or nodal velocity (or acceleration) is taken from FEM computation. NOEL should be 0 if Kirchhoff method (METHOD = 1) is used since elemental pressure is processed in FEM. NOEL should be 0 if Burton-Miller collocation method (METHOD = 4) is used since a constant strength element formulation is adopted. In other cases, it is strongly recommended to use element velocity or acceleration (NOEL = 0) if a T-Section appears in the boundary element mesh. See [Figure 21-1](#).
11. **NFRUP Field.** The preconditioner is obtained with the factorization of the influence coefficient matrix. To conserve CPU time, it can be retained for several frequencies. By default (NFRUP = 0), the preconditioner is updated for

every frequency. Note that in MPP version, the preconditioner is updated every NFRUP frequencies on each processor.

12. **Boundary Condition Cards.** Card 4.1 can be defined if the boundary elements are composed of several panels. It can be defined multiple times if more than 2 panels are used. Each Card 4.1 defines one panel.
13. **NSIDPC Field.** The field points where the panel contribution analysis is requested must be one of the field points for acoustic computation (it must be included in the nodes specified by the NSIDEXT or NSIDINT). The panels are defined by Cards 4 and 4.1.
14. **Element Sizing.** To obtain accurate results, the element size should not be greater than $1/6$ of the wave length λ ($\lambda = c/f$ where c is the wave speed and f is the frequency).
15. **Acoustic Transfer Vector.** The Acoustic Transfer Vector can be obtained by including the option ATV in the keyword. It calculates acoustic pressure (and sound pressure level) at field points due to unit normal velocity of each surface node. ATV is dependent on structure model, properties of acoustic fluid as well as location of field points. When ATV option is included, the structure does not need any external excitation, and the curve IDs LC1 and LC2 are ignored. A binary plot database d3atv can be obtained by setting `BINARY = 1` in `*DATABASE_FREQUENCY_BINARY_D3ATV`.
16. **Modal Acoustic Transfer Vector.** The Modal Acoustic Transfer Vector (MATV) is calculated when the MATV keyword option is included. The MATV option requires that the implicit eigenvalue solver be used, which is activated by keywords `*CONTROL_IMPLICIT_GENERAL`, and `*CONTROL_IMPLICIT_EIGENVALUE`. It calculates acoustic pressure (and sound pressure level) at field points due to vibration in the form of eigenmodes. For each excitation frequency f , LS-DYNA generates the pseudo-velocity boundary condition $2\pi i f \{\phi\}_j$, where $i = \sqrt{-1}$ is the imaginary unit and runs acoustic computation for each field point, based on the pseudo-velocity boundary conditions, to get the MATV matrices. The MATV matrices are saved in binary file `bin_bepressure` for future use. Like ATV, MATV is also only dependent on structure model, properties of acoustic fluids as well as the location of field points.
17. **Output Files.** The result files: `Press_Pa`, `Press_dB`, `Press_Pa_real`, `Press_Pa_imag`, `Press_Pa_t` and `Press_dB_t` have an xy-plot format that LS-PrePost can read and plot.

*FREQUENCY_DOMAIN

*FREQUENCY_DOMAIN_ACOUSTIC_FEM

*FREQUENCY_DOMAIN_ACOUSTIC_FEM_{OPTION}

Available options include:

EIGENVALUE

Purpose: Define an interior acoustic problem and solve the problem with a frequency domain finite element method. When the EIGENVALUE option is used, LS-DYNA computes eigenvalues and eigenvectors of the acoustic system.

VARIABLE**DESCRIPTION**

| | |
|--------|---|
| RO | Fluid density. |
| C | Sound speed of the fluid. GT.0: real constant sound speed. LT.0: C is the load curve ID, which defines the frequency dependent complex sound speed. See *FREQUENCY_DOMAIN_ACOUSTIC_SOUND_SPEED. |
| FMIN | Minimum value of output frequencies. |
| FMAX | Maximum value of output frequencies. |
| NFREQ | Number of output frequencies. |
| DTOUT | Time step for writing velocity or acceleration in the binary file. |
| TSTART | Start time for recording velocity or acceleration in transient analysis. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| PREF | Reference pressure for converting the acoustic pressure to dB. See Remark 3 . |
| FFTWIN | FFT windows (Default = 0): EQ.0: rectangular window. EQ.1: Hanning window. EQ.2: Hamming window. EQ.3: Blackman window. EQ.4: Raised cosine window. |
| PID | Part ID or part set ID to define the acoustic domain. |
| PTYP | Set type: EQ.0: part; see *PART. EQ.1: part set; see *SET_PART. |
| SID | Part ID, part set ID, segment set ID, or node set ID to define where the vibration boundary condition is. |
| STYP | Set type: EQ.0: part; see *PART. EQ.1: part set; see *SET_PART. EQ.2: segment set; see *SET_SEGMENT. EQ.3: node set; see *SET_NODE. |
| VAD | Boundary condition flag: EQ.0: velocity by steady state dynamics (SSD). EQ.1: velocity by transient analysis. EQ.2: opening (zero pressure). EQ.11: velocity by LCID1 (amplitude) and LCID2 (phase). EQ.12: velocity by LCID1 (real) and LCID2 (imaginary). EQ.21: acceleration by LCID1 (amplitude) and LCID2 (phase). EQ.22: acceleration by LCID1 (real) and LCID2 (imaginary). EQ.31: displacement by LCID1 (amplitude) and LCID2 (phase). EQ.32: displacement by LCID1 (real) and LCID2 (imaginary). |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | EQ.41: impedance by LCID1 (amplitude) and LCID2 (phase). EQ.42: impedance by LCID1 (real) and LCID2 (imaginary). EQ.51: pressure by LCID1 (amplitude) and LCID2 (phase). EQ.52: pressure by LCID1 (real) and LCID2 (imaginary). |
| DOF | Applicable degrees-of-freedom: EQ.0: determined by steady state dynamics. EQ.1: x -translational degree-of-freedom, EQ.2: y -translational degree-of-freedom, EQ.3: z -translational degree-of-freedom, EQ.4: translational motion in direction given by VID, EQ.5: normal direction of the element or segment. |
| LCID1 | Load curve ID to describe the amplitude (or real part) of velocity; see *DEFINE_CURVE. |
| LCID2 | Load curve ID to describe the phase (or imaginary part) of velocity; see *DEFINE_CURVE. |
| SF | Load curve scale factor. |
| VID | Vector ID for DOF values of 4. |
| NID | Node ID, node set ID, or segment set ID for acoustic result output. |
| NTYP | Set type: EQ.0: Node; see *NODE. EQ.1: Node set; see *SET_NODE. |
| IPFILE | Flag for output files (default = 0): EQ.0: Press_Pa (magnitude of pressure as function of frequency), Press_dB (sound pressure level or SPL as a function of frequency) are provided. EQ.1: Press_Pa_real (real part of pressure as a function of frequency) and Press_Pa_imag (imaginary part of pressure as a function of frequency) are provided, in addition to Press_Pa, Press_dB. |

| VARIABLE | DESCRIPTION |
|----------|--|
| DBA | <p>Flag for writing out weighted SPL files with different weighting options.</p> <p>EQ.0: No writing out weighted SPL files.</p> <p>EQ.1: write out Press_dB(A) by using A-weighting.</p> <p>EQ.2: write out Press_dB(B) by using B-weighting.</p> <p>EQ.3: write out Press_dB(C) by using C-weighting.</p> <p>EQ.4: write out Press_dB(D) by using D-weighting.</p> |

Remarks:

1. **Acoustic Problem.** This command solves the interior acoustic problems which is governed by Helmholtz equation $\nabla^2 p + k^2 p = 0$ with the boundary condition $\partial p / \partial n = -i\omega\rho v_n$, where p is the acoustic pressure; $k = \omega/c$ is the wave number; ω is the round frequency; c is the acoustic wave speed (sound speed); $i = \sqrt{-1}$ is the imaginary unit; ρ is the mass density; and v_n is the normal velocity. This command solves the acoustic problem in the frequency domain.
2. **Mass Density.** If mass density RO is not given, the mass density of PID (the part which defines the acoustic domain), will be used
3. **Reference Pressure.** PREF is the reference pressure to convert the acoustic pressure to dB $L_p = 10 \log_{10}(p^2/p_{\text{ref}}^2)$. Note that generally $p_{\text{ref}} = 20 \mu\text{Pa}$ for air.
4. **Material Models for Acoustic Domain.** If the boundary velocity is obtained from steady state dynamics ($VAD = 0$) using the keyword *FREQUENCY_DOMAIN_SSD, the part (PID) which defines the acoustic domain must use one of the following material models,
 - a) MAT_ELASTIC_FLUID
 - b) MAT_NULL (and EOS_IDEAL_GAS)

since only the above material models enable implicit eigenvalue analysis. If the boundary excitation is given by load curves LCID1 and LCID2 ($VAD > 0$), the part (PID) which defines the acoustic domain can use any material model which is compatible with 8-node solid elements, as only the mesh of the PID will be utilized in the computation. For example, MAT_ACOUSTIC and MAT_ELASTIC_FLUID can be used.

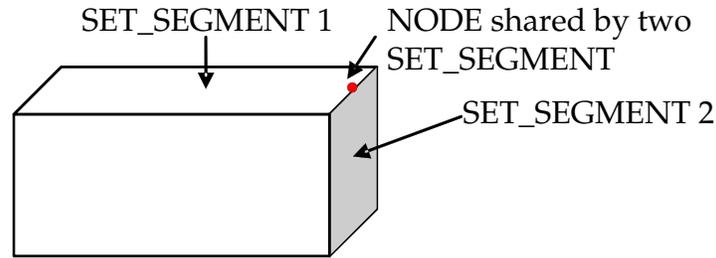

Figure 21-2. Nodes with Multiple Boundary Conditions.

5. **Steady State Dynamics.** If $VAD = 0$, the boundary excitation is given as velocity obtained from steady state dynamics. The other parameters in Card 3 (DOF, LCID1, LCID2, SF and VID) are ignored.
6. **Multiple Boundary Condition Definitions.** If a node's vibration boundary condition is defined multiple times, only the last definition is considered. This happens usually when a node is on edge and shared by two or more PART, SET_PART, SET_NODE, or SET_SEGMENT and a different vibration condition is defined on each of the SET_NODE or SET_SEGMENT. See [Figure 21-2](#).
7. **Output Files.** Results including acoustic pressure and SPL are given in d3acs binary files, which can be accessed by LS-PrePost. Nodal pressure and SPL values for nodes specified by NID and NTYP are given in ASCII file Press_Pa and Press_dB, which can be accessed by LS-PrePost. Press_Pa gives magnitude of the pressure. Press_dB gives the SPL in terms of dB.
8. **Frequencies and Steady State Dynamics.** If the boundary velocity condition is given by Steady State Dynamics ($VAD = 0$), the range and number of frequencies (FMIN, FMAX and NFREQ) should be compatible with the corresponding parameters in Card 1 of the keyword *FREQUENCY_DOMAIN_SSD.

*FREQUENCY_DOMAIN

*FREQUENCY_DOMAIN_ACOUSTIC_FRINGE_PLOT

*FREQUENCY_DOMAIN_ACOUSTIC_FRINGE_PLOT_OPTION

Available options include:

PART

PART_SET

NODE_SET

SPHERE

PLATE

Purpose: Define field points for acoustic pressure computation by the BEM acoustic solver and save the results to D3ACP binary database.

The field points can be defined as existing structure components if option PART, PART_SET or NODE_SET is used. The field points can be created by LS-DYNA if option SPHERE or PLATE is used.

Card Summary:

Card 1a. This card is included if and only if the keyword option is PART, PART_SET, or NODE_SET.

| | | | | | | | |
|---------|--|--|--|--|--|--|--|
| PID/SID | | | | | | | |
|---------|--|--|--|--|--|--|--|

Card 1b. This card is included if and only if the keyword option is SPHERE.

| | | | | | | | |

| Card 1a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---------|---|---|---|---|---|---|---|
| Variable | PID/SID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

VARIABLE**DESCRIPTION**

PID/SID

Part ID, part set ID, or node set ID.

SPHERE Card.

| Card 1b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|------|---------|------|------|------|---|---|
| Variable | CENTER | R | DENSITY | X | Y | Z | | |
| Type | I | F | I | F | F | F | | |
| Default | 1 | none | none | none | none | none | | |

VARIABLE**DESCRIPTION**

CENTER

Flag for defining the center point for the sphere.

EQ.1: mass center of the original structure.

EQ.2: geometry center of the original structure.

EQ.3: defined by (x, y, z) .

R

Radius of the sphere.

DENSITY

Parameter to define how coarse or dense the created sphere mesh is. It is a number between 3 and 39, where "3" gives you 24 elements while "39" gives you 8664 elements.

X

 x -coordinate of the center.

*FREQUENCY_DOMAIN

*FREQUENCY_DOMAIN_ACOUSTIC_FRINGE_PLOT

| VARIABLE | DESCRIPTION |
|----------|-------------------------------------|
| Y | <i>y</i> -coordinate of the center. |
| Z | <i>z</i> -coordinate of the center. |

Plate Card.

| Card 1c | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|-------|------|------|------|--------|--------|

| VARIABLE | DESCRIPTION |
|----------|---|
| NORM | Norm direction of the plate. EQ.1: <i>x</i> -direction EQ.2: <i>y</i> -direction EQ.3: <i>z</i> -direction |
| LEN_X | Length of longer side of the plate. |
| LEN_Y | Length of shorter side of the plate. |
| X | <i>x</i> -coordinate of the center. |
| Y | <i>y</i> -coordinate of the center. |
| Z | <i>z</i> -coordinate of the center. |
| NELM_X | Number of elements on longer side of the plate. |
| NELM_Y | Number of elements on shorter side of the plate. |

Remarks:

1. **LS-PrePost.** The acoustic pressure results at those field points are saved in D3ACP binary database and are accessible by LS-PrePost. With the FCOMP tool in LS-PrePost, the fringe plot of the results (real part acoustic pressure,

imaginary part acoustic pressure, magnitude of acoustic pressure and Sound Pressure Level) can be generated.

2. **Field Points.** The field points defined by this keyword are separate from the field points defined in Card 2 of *FREQUENCY_DOMAIN_ACOUSTIC_BEM. The acoustic pressure results for the latter are only saved in ASCII database Press_Pa, Press_dB, etc. (in a tabular format that can be plotted in LS-PrePost by using the XYPlot tool).

***FREQUENCY_DOMAIN** *FREQUENCY_DOMAIN_ACOUSTIC_INCIDENT_WAVE

***FREQUENCY_DOMAIN_ACOUSTIC_INCIDENT_WAVE**

Purpose: Define incident sound wave for acoustic scattering problems.

Wave Definition Cards. This card may be repeated to define multiple incident waves. Include as many cards as desired. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|---|---|---|
| Variable | TYPE | MAG | XC | YC | ZC | | | |
| Type | I | F | F | F | F | | | |
| Default | 1 | none | none | none | none | | | |

| VARIABLE | DESCRIPTION |
|------------|--|
| TYPE | Type of incident sound wave: EQ.1: plane wave. EQ.2: spherical wave. |
| MAG | Magnitude of the incident sound wave: GT.0: constant magnitude. LT.0: MAG is a curve ID, which defines the frequency dependent magnitude. See *DEFINE_CURVE. |
| XC, YC, ZC | Direction cosines for the plane wave (TYPE = 1) or coordinates of the point source for the spherical wave (TYPE = 2). |

Remarks:

1. **Plane Waves.** For plane waves, the incident wave is defined as

$$p(x, y, z) = A e^{-ik(\alpha x + \beta y + \gamma z)} ,$$

where A is the magnitude of the incident wave and α , β , and γ are the direction cosines along the incident direction. $i = \sqrt{-1}$ is the imaginary unit and $k = \omega/c$ is the wave number. ω is the round frequency and c is the sound speed.

2. **Spherical Waves.** For spherical waves, the incident wave is defined as

$$p(r) = A \frac{e^{-ikr}}{r} ,$$

where A is the magnitude of the incident wave and r is the distance measured from the position of the point source.

*FREQUENCY_DOMAIN

*FREQUENCY_DOMAIN_ACOUSTIC_SOUND_SPEED

*FREQUENCY_DOMAIN_ACOUSTIC_SOUND_SPEED

Purpose: Define frequency dependent complex sound speed to be used in frequency domain finite element method or boundary element method acoustic analysis.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | ID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|---|---|---|---|---|---|
| Variable | LCID1 | LCID2 | | | | | | |
| Type | I | I | | | | | | |
| Default | none | none | | | | | | |

VARIABLE

DESCRIPTION

| | |
|-------|---|
| ID | Complex sound speed ID. |
| LCID1 | Curve ID for real part of frequency dependent complex sound speed. |
| LCID2 | Curve ID for imaginary part of frequency dependent complex sound speed. |

Remarks:

- Acoustic Mediums and Damping.** The sound speed in an acoustic medium is usually defined as a constant real value. But it can also be defined as a complex value which is dependent on frequency, to introduce damping in the system.
- Using Complex Sound Speed.** To use the frequency dependent complex sound speed defined here, set the sound speed $C = -ID$ in *FREQUENCY_DO-

MAIN_ACOUSTIC_FEM or *FREQUENCY_DOMAIN_ACOUSTIC_BEM
keywords.

*FREQUENCY_DOMAIN

*FREQUENCY_DOMAIN_FRF

*FREQUENCY_DOMAIN_FRF

Purpose: This keyword computes frequency response functions due to nodal excitations.

NOTE: Natural frequencies and mode shapes are needed for computing the frequency response functions. Thus, keyword `*CONTROL_IMPLICIT_EIGENVALUE` *must* be included in input. See [Remark 1](#).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

| Variable | FMIN | FMAX | NFREQ | FSPACE | LCFREQ | RESTRT | OUTPUT | |
| Type | F | F | I | I | I | I | I | |
| Default | none | none | 2 | 0 | none | 0 | 0 | |

VARIABLE**DESCRIPTION**

| | |
|-------|--|
| N1 | Node / Node set / Segment set ID for excitation input. When VAD1, the excitation type, is set to 1, which is acceleration, this field is ignored. |
| N1TYP | Type of N1: EQ.0: node ID, EQ.1: node set ID, EQ.2: segment set ID. When VAD1, the excitation type, is set to 1, which is acceleration, this field is ignored. |
| DOF1 | Applicable degrees-of-freedom for excitation input (ignored if VAD1 = 4): EQ.0: translational movement in direction given by vector VID1, EQ.1: <i>x</i> -translational degree-of-freedom, or <i>x</i> -rotational degree-of-freedom (for torque excitation, VAD1 = 8) EQ.2: <i>y</i> -translational degree-of-freedom, or <i>y</i> -rotational degree-of-freedom (for torque excitation, VAD1 = 8), EQ.3: <i>z</i> -translational degree-of-freedom, or <i>z</i> -rotational degree-of-freedom (for torque excitation, VAD1 = 8). |
| VAD1 | Excitation input type: EQ.0: base velocity, EQ.1: base acceleration, EQ.2: base displacement, EQ.3: nodal force, |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | EQ.4: pressure, EQ.5: enforced velocity by large mass method, EQ.6: enforced acceleration by large mass method, EQ.7: enforced displacement by large mass method. EQ.8: torque, EQ.9: base angular velocity, EQ.10: base angular acceleration, EQ.11: base angular displacement |
| VID1 | Vector ID for DOF1 = 0 for excitation input, see *DEFINE_VECTOR. |
| FNMAX | Optional maximum natural frequency employed in FRF computation. See Remark 3 . |
| MDMIN | The first mode employed in FRF computation (optional). See Remarks 3 and 4 . |
| MDMAX | The last mode employed in FRF computation (optional). It should be set as a positive integer in a restart run (RESTART = 1 or 3) based on the number of eigenmodes available in the existing d3eigv database. See Remarks 3 and 4 . |
| DAMPF | Modal damping coefficient, ζ . See Remark 5 . |
| LCDAM | Load Curve ID defining mode dependent modal damping coefficient, ζ . See Remark 5 . |
| LCTYP | Type of load curve defining modal damping coefficient: EQ.0: Abscissa value defines frequency, EQ.1: Abscissa value defines mode number. See Remark 5 . |
| DMPMAS | Mass proportional damping constant, α , in Rayleigh damping. See Remark 5 . |
| DMPSTF | Stiffness proportional damping constant, β , in Rayleigh damping. See Remark 5 . |
| N2 | Node / Node set / Segment set ID for response output. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| N2TYP | Type of N2: EQ.0: node ID, EQ.1: node set ID, EQ.2: segment set ID. |
| DOF2 | Applicable degrees-of-freedom for response output: EQ.0: direction given by vector VID2, EQ.1: x -translational degree-of-freedom, EQ.2: y -translational degree-of-freedom, EQ.3: z -translational degree-of-freedom, EQ.4: x -rotational degree-of-freedom, EQ.5: y -rotational degree-of-freedom, EQ.6: z -rotational degree-of-freedom, EQ.7: x , y and z -translational degrees-of-freedom, EQ.8: x , y and z -rotational degrees-of-freedom. |
| VAD2 | Response output type: EQ.0: velocity, EQ.1: acceleration, EQ.2: displacement, EQ.3: nodal force (see Remark 8). |
| VID2 | Vector ID for DOF2 = 0 for response direction; see *DEFINE_-VECTOR. |
| RELATV | FLAG for displacement, velocity and acceleration results: EQ.0: absolute values are requested, EQ.1: relative values are requested (for VAD1 = 0, 1, 2 only). |
| FMIN | Minimum frequency for FRF output (cycles/time). See Remark 6 . |
| FMAX | Maximum frequency for FRF output (cycles/time). See Remark 6 . |
| NFREQ | Number of frequencies for FRF output. See Remark 6 . |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| FSPACE | Frequency spacing option for FRF output: EQ.0: linear, EQ.1: logarithmic, EQ.2: biased. See Remark 6 . |
| LCFREQ | Load Curve ID defining the frequencies for FRF output. See Remark 6 . |
| RESTRT | Restart option: EQ.0: initial run, EQ.1: restart with d3eigv family files, EQ.2: restart with dumpfrf, EQ.3: restart with d3eigv family files and dumpfrf. See Remark 7 . |
| OUTPUT | Output option: EQ.0: write amplitude and phase angle pairs, EQ.1: write real and imaginary pairs. |

Remarks:

- 1. Frequency Response Functions.** The FRF (frequency response functions) can be given as Displacement/Force (called Admittance, Compliance, or Receptance), Velocity/Force (called Mobility), Acceleration/Force (called Accelerance, Inertance), etc.
- 2. Enforced Motion.** The excitation input can be given as enforced motion (VAD1 = 5, 6, 7). Large mass method is used for this type of excitation input. The user need to attach a large mass to the nodes where the enforced motion is applied by using the keyword `*ELEMENT_MASS_{OPTION}`, and report the large mass per node (MPN) in the keyword `*CONTROL_FREQUENCY_DOMAIN`. For more details, please refer to `*CONTROL_FREQUENCY_DOMAIN`.
- 3. Maximum Frequency.** FNMAX decides how many natural vibration modes are adopted in FRF computation. LS-DYNA uses only modes with lower or equal frequency than FNMAX in FRF computation. If FNMAX is not given, the number of modes for the FRF computation is the same as the number of

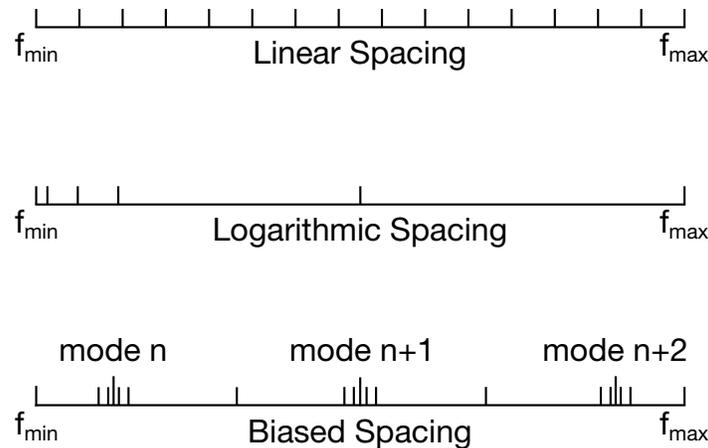

Figure 21-3. Spacing options of the frequency points.

modes, NEIG, from the *CONTROL_IMPLICIT_EIGENVALUE keyword card, unless MDMIN and MDMAX are prescribed (see [Remark 5](#)).

4. **Maximum/Minimum Mode.** MDMIN and MDMAX decide which mode(s) are adopted in FRF computation. This option is useful for calculating the contribution from a single mode (MDMIN = MDMAX) or several modes (MDMIN < MDMAX). If only MDMIN is given, LS-DYNA uses the single mode (MDMIN) to compute FRF. In a restart run based on existing eigenmode database d3eigv (RESTRT = 1 or 3), MDMAX should be a positive integer which is equal to or less than the number of eigenmodes available in d3eigv.
5. **Damping.** Damping can be prescribed in several ways:
 - a) To use a constant modal damping coefficient ζ for all the modes, define DAMPF only. LCDMP, LCTYP, DMPMAS and DMPSTF are ignored.
 - b) To use mode dependent modal damping, define a load curve (*DEFINE_CURVE) and specify that if the abscissa value defines the frequency or mode number by LCTYP. DMPMAS and DMPSTF are ignored.
 - c) To use Rayleigh damping, define DMPMAS (α) and DMPSTF (β) and keep DAMPF as 0.0, and keep LCDMP, LCTYP as 0. The damping matrix in Rayleigh damping is defined as $\mathbf{C} = \alpha\mathbf{M} + \beta\mathbf{K}$, where, \mathbf{C} , \mathbf{M} and \mathbf{K} are the damping, mass and stiffness matrices respectively.
6. **Frequency Points.** There are two methods to define the frequencies.
 - a) The first method is to define FMIN, FMAX, NFREQ and FSPACE. FMIN and FMAX specify the frequency range of interest and NFREQ specifies the number of frequencies at which results are required. FSPACE specifies the type of frequency spacing (linear, logarithmic or biased) to be used.

These frequency points for which results are required can be spaced equally along the frequency axis (on a linear or logarithmic scale). Or they can be biased toward the eigenfrequencies (the frequency points are placed closer together at eigenfrequencies in the frequency range) so that the detailed definition of the response close to resonance frequencies can be obtained. See [Figure 21-3](#).

- b) The second method is to use a load curve (LCFREQ) to define the frequencies of interest.
7. **RESTRT Field.** To save time in subsequent runs, the modal analysis stored in the d3eigv file during the first run can be reused by setting RESTRT = 1.

RESTRT = 2 or 3 is used when the user wants to add extra vibration modes to the FRF computation. After the initial FRF computation, the number of vibration modes may not be enough. For example, in the initial computation, the only vibration modes used may be up to 500 Hz. However, vibration modes at higher frequencies are needed, so just computing the extra modes (frequencies above 500 Hz) and adding the contribution from these extra modes to the previous FRF results is more efficient.

For RESTRT = 2, LS-DYNA runs a new modal analysis, reads in the previous FRF results (stored in the binary dump file dumpfrf), and adds the contribution from the new modes. For RESTRT = 3, LS-DYNA reads in d3eigv family files generated elsewhere, reads in dumpfrf, and adds the contribution from the new modes.

8. **Nodal Force Response Output.** For nodal force response (VAD2 = 3), the same nodes (or node set) need to be defined in *DATABASE_NODAL_FORCE_GROUP. In addition, the MSTRES field for the *CONTROL_IMPLICIT_EIGENVALUE keyword must be set to 1.

*FREQUENCY_DOMAIN_MODE_OPTION1_{OPTION2}

Available options for OPTION1 include:

- LIST
- GENERATE
- SET
- LOAD_PROJECTION
- MODAL_COEFFICIENT

For OPTION2 the available option is:

- <BLANK>
- EXCLUDE

Purpose: Define vibration modes to be used in modal superposition, modal acceleration or modal combination procedures for mode-based frequency domain analysis (such as frequency response functions, steady state dynamics, random vibration analysis and response spectrum analysis). When the option2 EXCLUDE is used, the modes defined in this keyword are excluded from participating in the modal superposition, modal acceleration, or modal combination procedures.

Card Summary:

Card 1a. This card is included if and only if OPTION1 is LIST. Include as many cards as necessary. This input ends at the next keyword ("*") card.

| | | | | | | | |
|------|------|------|------|------|------|------|------|

VARIABLE

DESCRIPTION

M n BEG First mode ID in block n .

M n END Last mode ID in block n . All mode ID's between and including M n BEG and M n END are added to the list.

Mode Set Card. For SET keyword option specify a mode set. Include only one card.

| Card 1c | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|---|---|---|---|---|---|---|
| Variable | SID | | | | | | | |
| Type | I | | | | | | | |

| VARIABLE | DESCRIPTION |
|----------|--|
| SID | Mode set identification (see *SET_MODE). |

LOAD_PROJECTION Card. For LOAD_PROJECTION keyword option specify the number of modes to be retained, which have the largest load projection ratios, or specify a threshold load projection ratio for mode truncation.

| Card 1d | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|-------|---|---|---|---|---|---|
| Variable | NMSORT | DSKIP | | | | | | |
| Type | I | F | | | | | | |

| VARIABLE | DESCRIPTION |
|----------|---|
| NMSORT | Number of modes to be retained which have the largest load projection ratios. |
| DSKIP | The threshold load projection ratio. All modes with load projection ratio less than this value will be skipped. |

MODAL_COEFFICIENT Card. For MODAL_COEFFICIENT keyword option specify a threshold modal coefficient ratio (over the largest modal coefficient) for mode truncation.

| Card 1d | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|---|---|---|---|---|---|
| Variable | DSKIP | | | | | | | |
| Type | F | | | | | | | |

| VARIABLE | DESCRIPTION |
|----------|---|
| DSKIP | The threshold modal coefficient ratio. All modes with the ratio of its modal coefficient over the largest modal coefficient less than this value will be skipped. |

Remarks:

1. **Excluding Modes.** This keyword can be used to remove the modes that add a much smaller contribution to the total structural response than the other modes from the modal superposition, modal acceleration or modal combination procedures of the mode-based frequency domain analysis.
2. **Overriding Mode Lists.** The mode list defined by this keyword overrides the modes specified by MDMIN, MDMAX (or FNMIX, FNMAX) in the keywords *FREQUENCY_DOMAIN_FRF, *FREQUENCY_DOMAIN_SSD, etc.

*FREQUENCY_DOMAIN_PATH_{OPTION}

Available options include:

<BLANK>

NOJOBID

PARTITION

Purpose: Specify the path and file name of binary databases, such as d3eigv, containing mode information for restarting frequency domain analyses such as FRF, SSD, Random vibration, and Response spectrum analysis.

The PARTITION option supports assigning different binary databases to different frequency ranges. Specifically, each frequency range can be associated with different eigenmodes and modal shape vectors provided by the binary database. This option provides a model for materials that have frequency-dependent properties.

Partition Cards. Card 1 for the PARTITION keyword option. Include one card for each frequency range. This input ends at the next keyword ("*") card. See Remark 3.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|----------|---|---|---|---|---|
| Variable | FBEG | FEND | FILENAME | | | | | |
| Type | F | F | C | | | | | |
| Default | none | none | none | | | | | |

Filename Card. Card 1 format used with the keyword option left blank.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|---|---|---|---|---|---|---|
| Variable | FILENAME | | | | | | | |
| Type | C | | | | | | | |
| Default | none | | | | | | | |

| VARIABLE | DESCRIPTION |
|----------|---|
| FBEG | Beginning frequency for using this database |

| | |
|----------|--|
| FEND | Ending frequency for using this database |
| FILENAME | Path to the database which contains modal information. |

Remarks:

1. **Binary File Location.** If the binary database files are in the runtime directory, this card is not needed for the case *without* partitioning.
2. **NOJOBID Option.** When the option NOJOBID is active, LS-DYNA will not add a prefix to the FILENAME on card 1. Even if the user is running LS-DYNA with *CASE or has JOBID in the command line, LS-DYNA will not add a prefix when NOJOBID is active.

To understand the intent of this feature recall that job ID numbers exist to ensure that filenames are unique so that output files are not overwritten for each calculation in some sequence. When the modal data is being read in as part of a restart calculation from some database already on disk, the default behavior is to replace FILENAME with FILENAME prefixed by the job ID. Consequently, without the NOJOBID option, reusing a single database across multiple modal analyses would involve either renaming or symbolically linking the existing file to the prefixed filename. The NOJOBID option circumvents this difficulty.

This is useful when the user wants to run multiple load cases for a single frequency domain analysis (FRF, SSD, random vibration, response spectrum analysis), and would like to run each load case with the restart option, RESTRT = 1, in *FREQUENCY_DOMAIN_FRF, or *FREQUENCY_DOMAIN_RANDOM_VIBRATION, or *FREQUENCY_DOMAIN_RESPONSE_SPECTRUM, etc., or RESTMD = 1 in *FREQUENCY_DOMAIN_SSD. In this case, with the option NOJOBID, a single eigenvector database, such as d3eigv, can be used for all the load cases.

3. **Frequency Partition.** When the option PARTITION is active, the binary database designated by FILENAME is used for the frequency range starting from (and including) FBEG and ending at (not including) FEND.

***FREQUENCY_DOMAIN_RANDOM_VIBRATION**

Available options include:

<BLANK>

FATIGUE

Purpose: Set random vibration control options. When FATIGUE option is used, compute fatigue life of structures or parts under random vibration.

VARIABLE**DESCRIPTION**

MDMIN

The first mode in modal superposition method (optional).

MDMAX

The last mode in modal superposition method (optional).

| VARIABLE | DESCRIPTION |
|-----------------|---|
| FNMIN | The minimum natural frequency in modal superposition Method (optional). |
| FNMAX | The maximum natural frequency in modal superposition method (optional). |
| RESTRT | Restart option. EQ.0: A new modal analysis is performed, EQ.1: Restart with d3eigv. |
| RESTRM | Restart option when different types of loads are present. EQ.0: don't read the dump file for PSD and RMS, EQ.1: read in PSD and RMS values from the dump file and add them to the values computed in the current load case. |
| DAMPF | Modal damping coefficient, ζ . |
| LCDAM | Load Curve ID defining mode dependent modal damping coefficient ζ . |
| LCTYP | Type of load curve defining modal damping coefficient EQ.0: Abscissa value defines frequency, EQ.1: Abscissa value defines mode number. |
| DMPMAS | Mass proportional damping constant α , in Rayleigh damping. |
| DMPSTF | Stiffness proportional damping constant β , in Rayleigh damping. |
| DMPTYP | Type of damping EQ.0: modal damping. EQ.1: broadband damping. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| VAFLAG | Loading type: EQ.0: No random vibration analysis. EQ.1: Base acceleration. EQ.2: Random pressure. EQ.3: Plane wave. EQ.4: Shock wave. EQ.5: Progressive wave. EQ.6: Reverberant wave. EQ.7: Turbulent boundary layer wave. EQ.8: Nodal force. EQ.9: Base velocity. EQ.10: Base displacement. EQ.11: Enforced acceleration by large mass method (see remark 15). EQ.12: Enforced velocity by large mass method (see remark 15). EQ.13: Enforced displacement by large mass method (see remark 15). |
| METHOD | Method for modal response analysis. EQ.0: method set automatically by LS-DYNA (recommended) EQ.1: modal superposition method EQ.2: modal acceleration method EQ.3: modal truncation augmentation method |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| UNIT | Flag for acceleration unit conversion: EQ.0: use [length unit]/[time unit] ² as unit of acceleration. EQ.1: use g as unit for acceleration, and SI units (Newton, kg, meter, second, etc.) elsewhere. EQ.2: use g as unit for acceleration, and Engineering units (lbf, lbf × second ² /inch, inch, second, etc.) elsewhere. EQ.3: use g as unit for acceleration, and units (kN, kg, mm, ms, GPa, etc.) elsewhere. EQ.-1: use g as unit for acceleration and provide the multiplier for converting g to [length unit]/[time unit] ² . |
| UMLT | Multiplier for converting g to [length unit]/[time unit] ² (used only for UNIT = -1). |
| VAPSD | Flag for PSD output: EQ.0: Absolute PSD output is requested. EQ.1: Relative PSD output is requested (used only for VAFLAG = 1) |
| VARMS | Flag for RMS output: EQ.0: Absolute RMS output is requested. EQ.1: Relative RMS output is requested (used only for VAFLAG = 1) |
| NAPSD | Number of auto PSD load definition. Card 5a is repeated "NAPSD" times, one for each auto PSD load definition. The default value is 1. |
| NCPSD | Number of cross PSD load definition. Card 5b is repeated "NCPSD" times, one for each cross PSD load definition. The default value is 0. |
| LDTYP | Excitation load (LDPSD in card 5) type: EQ.0: PSD. EQ.1: SPL (for plane wave only). EQ.2: time history load. |
| IPANELU | Number of strips in U direction (used only for VAFLAG = 5, 6, 7) |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| IPANELV | Number of strips in V direction (used only for VAFLAG = 5, 6, 7) |
| TEMPER | Temperature |
| LDFLAG | Type of loading curves. EQ.0: Log-Log interpolation (default) EQ.1: Semi-Log interpolation EQ.2: Linear-Linear interpolation |
| SID | GE.0: Set ID for the panel exposed to acoustic environment, or the nodes subjected to nodal force excitation, or nodal acceleration excitation. For VAFLAG = 1, base acceleration, leave this as blank LT.0: used to define the cross-PSD. SID is the ID of the load cases. |
| STYPE | Flag specifying meaning of SID. EQ.0: Node EQ.1: Node Set EQ.2: Segment Set EQ.3: Part EQ.4: Part Set LT.0: used to define the cross-psd. STYPE is the ID of the load cases. |
| DOF | Applicable degrees-of-freedom for nodal force excitation or base acceleration (DOF = 1, 2, and 3), or wave direction: EQ.0: translational movement in direction given by vector VID, EQ.1: x-translational degree-of-freedom, EQ.2: y-translational degree-of-freedom, EQ.3: z-translational degree-of-freedom. |
| LDPSD | Load curve for PSD, SPL, or time history excitation. |
| LDVEL | Load curve for phase velocity. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| LDFLW | Load curve for exponential decay for TBL in flow-wise direction |
| LDSPN | Load curve for exponential decay for TBL in span-wise direction |
| CID/VID | Coordinate system ID for defining wave direction, see *DEFINE_COORDINATE_SYSTEM; or Vector ID for defining load direction for nodal force, or base excitation, see *DEFINE_VECTOR. |
| LOAD_I | ID of load i for cross PSD. |
| LOAD_J | ID of load j for cross PSD. |
| LCTYP2 | Type of load curves (LDPSD1 and LDPSD2) for defining cross PSD: EQ.0: LDPSD1 defines real part and LDPSD2 defines imaginary part EQ.1: LDPSD1 defines magnitude and LDPSD2 defines phase angle (in degrees) EQ.2: LDPSD1 defines magnitude and LDPSD2 defines phase angle (in radians) |
| LDPSD1 | Load curve for real part or magnitude of cross PSD |
| LDPSD2 | Load curve for imaginary part or phase angle of cross PSD |
| MFTG | Method for random fatigue analysis (for option_FATIGUE). EQ.0: no fatigue analysis, EQ.1: Steinberg's three-band method, EQ.2: Dirlik method, EQ.3: Narrow band method, EQ.4: Wirsching method, EQ.5: Chaudhury and Dover method, EQ.6: Tunna method, EQ.7: Hancock method, EQ.8: Lalanne method. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| NFTG | <p>Field specifying the number of S - N curves to be defined.</p> <p>GE.0: Number of S - N curves defined by card 6. Card 6 is repeated "NFTG" number of times, one for each S - N fatigue curve definition. The default value is 1.</p> <p>EQ.-999: S - N curves are defined through *MAT_ADD_FATIGUE.</p> <p>If the option FATIGUE is not used, ignore this parameter.</p> |
| SNTYPE | <p>Stress type of S - N curve in fatigue analysis.</p> <p>EQ.0: von-mises stress</p> <p>EQ.1: maximum principal stress (not implemented)</p> <p>EQ.2: maximum shear stress (not implemented)</p> <p>EQ.-n: The nth stress component.</p> |
| TEXPOS | <p>Exposure time (used if option FATIGUE is used)</p> |
| STRSF | <p>Stress scale factor to accommodate different ordinates in S - N curve.</p> <p>EQ.1: used if the ordinate in S - N curve is stress range (default)</p> <p>EQ.2: used if the ordinate in S - N curve is stress amplitude</p> |
| INFTG | <p>Flag for including initial damage ratio.</p> <p>EQ.0: no initial damage ratio,</p> <p>GT.0: read existing d3ftg files to get initial damage ratio. When INFTG > 1, it means that the initial damage ratio comes from multiple loading cases (correspondingly, multiple binary databases, defined by Card 7). The value of INFTG should be ≤ 10.</p> |
| PID | <p>Part ID, or Part Set ID, or Element (solid, shell, beam, thick shell) Set ID.</p> |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| LCID | S - N fatigue curve ID for the current Part or Part Set. GT.0: S - N fatigue curve ID EQ.-1: S - N fatigue curve uses equation $NS^b = a$ EQ.-2: S - N fatigue curve uses equation $\log(S) = a - b \log(N)$ EQ.-3: S - N fatigue curve uses equation $S = a N^b$ |
| PTYPE | Type of PID. EQ.0: Part (default) EQ.1: Part Set EQ.2: SET_SOLID EQ.3: SET_BEAM EQ.4: SET_SHELL EQ.5: SET_TSHELL |
| LTYPE | Type of LCID. EQ.0: Semi-log interpolation (default) EQ.1: Log-Log interpolation EQ.2: Linear-Linear interpolation |
| A | Material parameter a in S - N fatigue equation. |
| B | Material parameter b in S - N fatigue equation. |
| STHRES | Fatigue threshold (applicable only if LCID < 0). |

| VARIABLE | DESCRIPTION |
|----------|---|
| SNLIMT | <p><u>If LCID > 0</u></p> <p>Flag setting algorithm used when stress is lower than the lowest stress on S - N curve (if LCID > 0), or lower than STHRES (if LCID < 0).</p> <p>EQ.0: use the life at the last point on S - N curve</p> <p>EQ.1: extrapolation from the last two points on S - N curve (only applicable if LCID > 0)</p> <p>EQ.2: infinity.</p> <p><u>If LCID < 0</u></p> <p>Flag setting algorithm used when stress is lower STHRES</p> <p>EQ.0: use the life at STHRES</p> <p>EQ.1: <i>Ignored.</i> only applicable for LCID > 0</p> <p>EQ.2: infinity.</p> |
| FILENAME | Path and name of existing binary database for fatigue information. |

Remarks:

1. **Historical Background.** This command evaluates the structural random vibration response due to aero acoustic loads, base excitation, or nodal force. This capability originated in Boeing's in-house code N-FEARA, which is a NI-KE3D-based Finite Element tool for performing structural analysis with vibro-acoustic loads. The main developer of N-FEARA is Mostafa Rassaian from the Boeing Company.
2. **Fatigue.** To run this option, it is required that MSTRES = 1 in the keyword *CONTROL_IMPLICIT_EIGENVALUE. This is because the fatigue analysis is depends on stresses.
3. **IPANEL.** The number of strips the in U and V direction are used to group the elements and thereby reduce the number integration domains reducing computational expense. This option is only available for VAFLAG = 5, 6, and 7.
4. **Restarting.** Restart option RESTRT = 1 is used when mode analysis has been done previously. In this case, LS-DYNA skips modal analysis and reads in the d3eigv files from the prior execution. For RESTMD = 1, always use MDMIN = 1 and set MDMAX to the number of modes in the previous run (this

can be found in the ASCII file `eigout`, or it can be extracted from the `d3eigv` files using LS-PrePost).

5. **Accumulated Fatigue.** The fatigue damage ratio can be accumulated over multiple load cases by setting `INFTG = 1`. This is useful when a structure is subjected to multiple independent random vibrations. LS-DYNA calculates the total damage ratio by adding the damage ratio from the current calculation to the damage ratio of the previous calculation which are stored in the previous calculation's fatigue database (`d3ftg` by default). The previous `d3ftg` file will be overwritten by the new one, if it is in the same directory.
6. **Automatic Method Selection.** If `METHOD = 0`, LS-DYNA uses modal superposition method for cases (`VAFLAG`) 4, 5, 6, 7; For cases 1, 2, 3 and 8, LS-DYNA uses modal superposition method when preload condition is present and uses modal acceleration method when preload condition is not present.
7. **Units.** In a set of consistent units, the unit for acceleration is defined as

$$1 \text{ (acceleration unit)} = \frac{1(\text{length unit})}{[1(\text{time unit})]^2}$$

Some users in industry prefer to use `g` (acceleration due to gravity) as the unit for acceleration. For example,

$$1g = 9.81 \frac{\text{m}}{\text{s}^2} = 386.089 \frac{\text{inch}}{\text{s}^2}$$

If the input and output use `g` as the unit for acceleration, select `UNIT = 1, 2, or 3`.

If `UNIT = 3`, a multiplier (`UMLT`) for converting `g` to `[length unit]/[time unit]2` is needed and it is defined by

$$1g = \text{UMLT} \times \frac{[\text{length unit}]}{[\text{time unit}]^2}$$

For more information about the consistent units, see `GS.21 (GETTING STARTED)`.

8. **Restrictions on Load Curves.** The load curves `LDPSD`, `LDVEL`, `LDFLW`, and `LDSPN` must all be defined using the same number of points. The number of points in the load curve `LDDAMP` can be different from those for `LDPSD`, `LDVEL`, `LDFLW`, and `LDSPN`.
9. **Wave direction.** Wave direction is determined `DOF` and `CID/VID`. `CID/VID` represents a local `U-V-W` coordinate system for defining acoustic wave direction, only partially correlated waves (`VAFLAG=5, 6, 7`) need this local coordinate system. For nodal force, base excitation, plane wave or random pressure, `CID` represents a vector ID defining the load direction (`DOF = ±4`).

10. **Stress / Strain computation.** To get stress results (PSD and RMS) from random vibration analysis, MSTRES field of the *CONTROL_IMPLICIT_EIGENVALUE keyword should be set to 1. To get strain results (PSD and RMS) the STRFLG field of *DATABASE_EXTENT_BINARY should be set to 1. To get stress component results for beam elements (which are not based on resultant formulation), the BEAMIP field of *DATABASE_EXTENT_BINARY should be set greater than 0.
11. **Binary plot databases.** PSD and RMS results are given for all nodes and elements. PSD results are written in binary to a file named d3psd. Similarly, RMS results are written in binary to a file named d3rms. See the keyword *DATABASE_FREQUENCY_BINARY_{OPTION} for more details.
12. **ASCII Output for Displacement.** Displacement, velocity, and acceleration PSD results are output into ASCII file nodout_psd. The set nodes for which data is written to nodout_psd is specified with the *DATABASE_HISTORY_NODE keyword.
13. **ASCII Output for Stress.** Stress PSD results are output into ASCII file elout_psd. The set of solid, beam, shell, and thick shell elements to be written to the elout_psd file are specified with the following keywords: *DATABASE_HISTORY_SOLID, *DATABASE_HISTORY_BEAM, *DATABASE_HISTORY_SHELL, *DATABASE_HISTORY_TSHELL.
14. **Cross PSD.** The cross PSD can be defined as complex variables to consider phase difference. In that case, two curves are needed to define the cross PSD (LCPSD1 and LCPSD2). Two load IDs are needed to define the cross PSD (LOAD_I and LOAD_J). They are simply the ordering numbers by which the auto PSDs are defined. For example, the first Card 5a defines load 1 and the second Card 5a defines the load 2. No cross PSD is required if two loads are uncorrelated. Cross PSD for any pair of two correlated loads is defined only once – from lower load ID to higher load ID (e.g. 1->2, 1->3, 2->3, ...). The cross PSD from higher load ID to lower load ID (e.g. 2->1, 3->1, 3->2, ...) is added by LS-DYNA automatically by using the relationship

$$G_{ji} = \overline{G_{ij}}$$

where G_{ij} is the cross PSD from load i to load j , and $\overline{}$ represents the complex conjugate.

15. **Large Mass Method.** For the cases with enforced motion excitation such as nodal velocity, acceleration, or displacement, the large mass method can be used to compute the random vibration response. The excitation input can be given as enforced motion curves (VAFLAG = 11, 12, 13). To use the large mass method, the user need to attach a large mass to the nodes where the enforced

motion is applied by using the keyword `*ELEMENT_MASS_{OPTION}`, and report the large mass per node (MPN) in the keyword `*CONTROL_FREQUENCY_DOMAIN`. For more details, please refer to `*CONTROL_FREQUENCY_DOMAIN`.

16. **Cross Correlation.** Cross correlation can be defined only for same type of excitations (e.g. nodal force, random pressure). Correlation between different types of excitations is not allowed
17. **Output for Fatigue Data.** When the FATIGUE option is used, a binary plot file, d3ftg, is written. 5 results are included in d3ftg:
 - Result 1. Cumulative damage ratio
 - Result 2. Expected fatigue life
 - Result 3. Zero-crossing frequency
 - Result 4. Peak-crossing frequency
 - Result 5. Irregularity factor

These results are given as element variables. Irregularity factor is a real number from 0 to 1. A sine wave has irregularity factor as 1, while white noise has irregularity factor as 0. The lower the irregularity factor, the closer the process is to the broad band case.

18. **Stress Threshold for Fatigue.** In some materials, the S–N curve flattens out eventually, so that below a certain threshold stress STHRES failure does not occur no matter how long the loads are cycled. SNLIMT can be set to 2 in this case; For other materials, such as aluminum, no threshold stress exists and SNLIMT should be set to 0 or 1 for added level of safety.
19. **Restriction on Fatigue Cards.** When the FATIGUE option is used, all fatigue cards (Card 6) *must* be of the same PTYPE (PART or SET of ELEMENTS).
20. **Format for S - N Curves.** S - N curves can be defined by `*DEFINE_CURVE`, or for LCID<0 by

$$NS^b = a$$

when LCID = -1 or for LCID = -2

$$\log(S) = a - b \log(N)$$

or for LCID = -3

$$S = a N^b$$

where N is the number of cycles for fatigue failure and S is the stress amplitude. Please note that the two equations can be converted to each other, with some minor manipulation on the constants a and b .

| DMPMAS | Mass proportional damping constant α , in Rayleigh damping. |
| DMPSTF | Stiffness proportional damping constant β , in Rayleigh damping. |
| LCTYP | Load curve type for defining the input spectrum. EQ.0: base velocity (vs. natural frequency), EQ.1: base acceleration (vs. natural frequency), EQ.2: base displacement (vs. natural frequency), EQ.3: nodal force (vs. natural frequency), EQ.4: pressure (vs. natural frequency), EQ.5: base velocity (vs. natural period), EQ.6: base acceleration (vs. natural period), EQ.7: base displacement (vs. natural period), EQ.8: nodal force (vs. natural period), EQ.9: pressure (vs. natural period), EQ.10: base velocity time history, EQ.11: base acceleration time history, EQ.12: base displacement time history. |
| DOF | Applicable degrees-of-freedom for excitation input: EQ.1: x-translational degree-of-freedom, EQ.2: y-translational degree-of-freedom, EQ.3: z-translational degree-of-freedom, EQ.4: translational movement in direction given by vector VID. |
| LC/TBID | Load curve or table ID, see *DEFINE_TABLE, defining the response spectrum for frequencies. If the table definition is used a family of curves are defined for discrete critical damping ratios. |
| SF | Scale factor for the input load spectrum. |
| VID | Vector ID for DOF values of 4. |

| | |
|--------|---|
| LNID | Node ID, or node set ID, or segment set ID where the excitation is applied. If the input load is given as base excitation spectrum, LNID = 0 |
| LNTYP | Set type for LNID: EQ.1: Node, see *NODE, EQ.2: Node set, see *SET_NODE, EQ.3: Segment set, see *SET_SEGMENT, EQ.4: Part, see *PART, EQ.5: Part set, see *SET_PART. |
| INFLAG | Frequency interpolation option EQ.0: Logarithmic interpolation, EQ.1: Semi-logarithmic interpolation. EQ.2: Linear interpolation. |
| STD | Design spectrum standard for shock load EQ.1: NRL-1396, EQ.-1: Spectrum constants defined by user in Card 5. |
| UNIT | Unit system EQ.1: MKS (kg, m, s, N, Pa) EQ.2: GPA (kg, mm, ms, kN, GPa) EQ.3: MPA (ton, mm, s, N, MPa) EQ.4: BIN (lb, in, s, lbf, psi) EQ.5: miu_MKS (gm, mm, ms, N, N/mm ²) EQ.6: CGS (gm, cm, s, dyne, dyne/cm ²) |
| AMIN | Minimum acceleration (in g - gravity acceleration) |
| VID | Direction of shock load EQ.1: x-direction EQ.2: y-direction EQ.3: z-direction < 0: direction is given by vector VID |

| | |
|-----------|--|
| XC | X-directional cosine of shock load (if VID is undefined) |
| YC | Y-directional cosine of shock load (if VID is undefined) |
| ZC | Z-directional cosine of shock load (if VID is undefined) |
| EFFMAS | Minimum percentage requirement of total modal mass |
| SHPTYP | Ship type EQ.1: Submarine EQ.2: Surface ship |
| MOUNT | Mount type EQ.1: Hull Mounted System EQ.2: Deck Mounted System EQ.3: Shell Plating Mounted System |
| MOVEMT | Movement type EQ.1: Vertical EQ.2: Athwartship EQ.3: Fore and Aft |
| MATTYP | Material type EQ.1: Elastic EQ.2: Elasto-plastic |
| AF, AA-AD | Coefficients to define the acceleration spectrum (see Remark 11) |
| VF, VA-VC | Coefficients to define the velocity spectrum (see Remark 11) |
| SID | Mode set ID (see *SET_MODE) |

Remarks:

1. This command uses modal superposition method to evaluate the maximum response of a structure subjected to input response spectrum load, such as the acceleration spectrum load in earthquake engineering.
2. Modal analysis has to be performed preceding the response spectrum analysis. Thus the keywords *CONTROL_IMPLICIT_GENERAL and *CONTROL_IMPLICIT_EIGENVALUE are expected in the input file.

3. MDMIN, MDMAX, FNMIN and FNMAX should be set appropriately to cover all the natural modes inside the input spectrum.
4. To include stress results, modal stress computation has to be requested in *CONTROL_IMPLICIT_EIGENVALUE (set MSTRES = 1).
5. For base excitation cases, user can choose relative values or absolute values for displacement, velocity and acceleration results output.
6. RESTRT = 1 enables a fast restart run based on d3eigv family files generated in last run or elsewhere. LS-DYNA reads d3eigv family files to get the natural vibration frequencies and mode shapes. If the d3eigv family files are located in a directory other than the working directory, the directory must be specified in *FREQUENCY_DOMAIN_PATH.
7. For Double Sum method (MCOMB = 3), earthquake duration time is given by ENDTIM in the keyword *CONTROL_TERMINATION.
8. Three interpolation options are available for frequency interpolation when reading response spectrum values

- a) When INFLAG = 0 (default), logarithmic interpolation is used, e.g.

$$\frac{\log y - \log y_1}{\log x - \log x_1} = \frac{\log y_2 - \log y_1}{\log x_2 - \log x_1}$$

- b) When INFLAG = 1, semi-logarithmic interpolation is used, e.g.

$$\frac{\log y - \log y_1}{x - x_1} = \frac{\log y_2 - \log y_1}{x_2 - x_1}$$

- c) When INFLAG = 2, linear interpolation is used, e.g.

$$\frac{y - y_1}{x - x_1} = \frac{y_2 - y_1}{x_2 - x_1}$$

9. Linear interpolation is used for interpolation with respect to damping ratios.
10. If the load curve is defined as base velocity, base acceleration or base displacement time history (LCTYP = 10, 11 or 12), an ASCII xyplot database spectrum_curve_printID is generated. It shows the intermediate base acceleration spectrum converted from the time history data. ID is the ordering of the input spectra (defined in Card 3). For single point response spectrum, ID is 1.
11. For DDAM option, LS-DYNA performs Dynamic Design Analysis Method (DDAM) on shipboard equipment and supporting structures, subject to shock load due to underwater explosions (UNDEX). The DDAM spectrum can be provided by Naval Research Laboratory Memorandum Report NRL-1396 (STD = 1) or defined by user (STD = -1) using coefficients defined in Card 4b and Card 5.

12. The user defined acceleration input spectrum is defined as (if $A_d \neq 0$)

$$A = A_f \bullet A_a \frac{(A_b + W) \bullet (A_c + W)}{(A_d + W)^2}$$

or (if $A_d = 0$)

$$A = A_f \bullet A_a \frac{(A_b + W)}{(A_c + W)}$$

The user defined velocity input spectrum is defined as

$$V = V_f \bullet V_a \frac{(V_b + W)}{(V_c + W)}$$

Where W is modal weight in thousands of pounds (Kips).

***FREQUENCY_DOMAIN_SSD_{OPTION}**

Available options include:

FATIGUE

FRF

ERP

Purpose: Compute steady state dynamic response due to given spectrum of harmonic excitations.

When the FATIGUE option is applied LS-DYNA also calculates the cumulative fatigue damage ratio. When the FRF option is applied LS-DYNA calculates the steady state dynamic response due to unit load, which is equivalent to Frequency Response Function (FRF). When the ERP option is applied LS-DYNA also calculates the Equivalent Radiated Power (ERP) due to vibration.

| VARIABLE | DESCRIPTION |
|----------|---|
| MDMIN | The first mode in modal superposition method (optional). |
| MDMAX | The last mode in modal superposition method (optional). |
| FNMIN | The minimum natural frequency in modal superposition method (optional). |
| FNMAX | The maximum natural frequency in modal superposition method (optional). |
| RESTMD | Restart option: EQ.0: A new modal analysis is performed, EQ.1: Restart with d3eigv, EQ.2: Restart with "modeshp" binary scratch file. |
| RESTDP | Restart option: EQ.0: A new run without dumpssd, EQ.1: Restart with dumpssd. |
| LCFLAG | Load Curve definition flag. EQ.0: load curves are given as amplitude / phase angle (defined in degrees in the range (-180°, 180°)), EQ.1: load curves are given as real / imaginary components. |
| RELATV | Flag for displacement, velocity and acceleration results: EQ.0: absolute values are requested, EQ.1: relative values are requested (for VAD = 2, 3 and 4 only). |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| DAMPF | Modal damping coefficient, ζ . |
| LCDAM | Load Curve ID defining mode dependent modal damping coefficient ζ . |
| LCTYP | Type of load curve defining modal damping coefficient. EQ.0: Abscissa value defines frequency, EQ.1: Abscissa value defines mode number. |
| DMPMAS | Mass proportional damping constant α , in Rayleigh damping. |
| DMPSTF | Stiffness proportional damping constant β , in Rayleigh damping |
| DMPFLG | Damping flag: EQ.0: use modal damping coefficient ζ , defined by DAMPF, or LCDAM, or Rayleigh damping defined by DMPMAS and DMPSTF in this card. EQ.1: use damping defined by *DAMPING_PART_MASS and *DAMPING_PART_STIFFNESS. |
| MEMORY | Memory flag: EQ.0: modal superposition will be performed in-core. This option runs faster. EQ.1: modal superposition will be performed out-of-core. This is needed for some large scale problems that cannot fit in main memory. This method incurs a performance penalty associated with disk speed. |
| NERP | Number of ERP panels. |
| STR TYP | Stress used in fatigue analysis: EQ.0: Von Mises stress, EQ.1: Maximum principal stress, EQ.2: Maximum shear stress. |
| NOU T | Part, part set, segment set, or node set ID for response output (use with acoustic computation). See NOTYP below. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| NOTYP | Type of NOUT: EQ.0: part set ID (not implemented), EQ.1: part ID (not implemented), EQ.2: segment set ID, EQ.3: node set ID, EQ.-2: segment set ID which mismatches with acoustic boundary nodes. Mapping of velocity or acceleration to the acoustic boundary nodes is performed. |
| NOVA | Response output type. EQ.0: velocity, EQ.1: acceleration. |
| RO | Fluid density. |
| C | Sound speed of the fluid. |
| ERPRLF | ERP radiation loss factor. |
| ERPREF | ERP reference value. This is used to convert the absolute ERP value to ERP in decibels (dB). |
| PID | Part, part set, or segment set ID for ERP computation. See PTYP below. |
| PTYP | Type of PID: EQ.0: part ID, EQ.1: part set ID, EQ.2: segment set ID. |
| NID | Node, node set, or segment set ID for excitation input. See NTYP below. |
| NTYP | Type of NID. EQ.0: node ID, EQ.1: node set ID, EQ.2: segment set ID. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| DOF | <p>Applicable degrees-of-freedom for excitation input (ignored if VAD = 1).</p> <p>EQ.1: x-translational degree-of-freedom or x-rotational degree-of-freedom (for torque excitation, VAD = 8),</p> <p>EQ.2: y-translational degree-of-freedom, or y-rotational degree-of-freedom (for torque excitation, VAD = 8),</p> <p>EQ.3: z-translational degree-of-freedom, or z-rotational degree-of-freedom (for torque excitation, VAD = 8),</p> <p>EQ.4: translational movement in direction given by vector VID, or rotational movement with axis given by vector VID (for torque excitation, VAD = 8).</p> |
| VAD | <p>Excitation input type:</p> <p>EQ.0: nodal force,</p> <p>EQ.1: pressure,</p> <p>EQ.2: base velocity,</p> <p>EQ.3: base acceleration,</p> <p>EQ.4: base displacement,</p> <p>EQ.5: enforced velocity by large mass method (see remark 10),</p> <p>EQ.6: enforced acceleration by large mass method (see remark 10),</p> <p>EQ.7: enforced displacement by large mass method (see remark 10),</p> <p>EQ.8: torque,</p> <p>EQ.9: base angular velocity,</p> <p>EQ.10: base angular acceleration,</p> <p>EQ.11: base angular displacement.</p> |
| LC1 | <p>Load Curve ID defining amplitude (LCFLAG = 0) or real (in-phase) part (LCFLAG = 1) of load as a function of frequency. It is not used if the option FRF is active.</p> |
| LC2 | <p>Load Curve ID defining phase angle (LCFLAG = 0) or imaginary (out-phase) part (LCFLAG = 1) of load as a function of frequency. It is not used if the option FRF is active.</p> |

| VARIABLE | DESCRIPTION |
|----------|--|
| LC3 | Load Curve ID defining load duration for each frequency. This parameter is optional and is only needed for fatigue analysis. |
| VID | Vector ID for DOF = 4 for excitation input, see *DEFINE_VECTOR. |

Remarks:

1. This command computes steady state dynamic response due to harmonic excitation spectrum by modal superposition method.
2. Natural frequencies and mode shapes are needed for running the modal superposition method. Thus, the keyword *CONTROL_IMPLICIT_EIGENVALUE *must* be included in input.
3. MDMIN/MDMAX and FNMIN/FNMAX together determine which modes are used in modal superposition method. The first mode must have a mode number \geq MDMIN, and frequency \geq FNMIN; the last mode must have mode number \leq MDMAX, and frequency \leq FNMAX. When MDMAX or FNMAX is not given, the last mode in modal superposition method is the last mode available in FILENM.
4. Restart option RESTMD = 1 is used if mode analysis has been done previously. In this case, LS-DYNA skips modal analysis and reads in d3eigv family files generated previously. Restart option RESTMD = 2 is used if a SSD analysis has been done for the same model previously and the binary scratch file "modeshp" exists. The "modeshp" file saves condensed modal shape (and modal stress if there is any) data. So user can restart SSD analysis with existing "modeshp" file with RESTMD = 2 if user is sure that no any change on modal structure, boundary conditions and material models is made (as the result, "modeshp" file is not changed). Restarting SSD with RESTMD = 2 is faster than restarting SSD with RESTMD = 1 since one can reuse the available "modeshp" file. For RESTMD = 1 or 2, always use MDMIN = 1 and MDMAX = number of modes given by modal analysis (can be found from ASCII file eigout, or from d3eigv files using LS-PREPOST).
5. Restart option RESTDP = 1 is used if user wants to add contribution of additional modes to previous SSD results. In this case, LS-DYNA reads in binary dump file dumpssd which contains previous SSD results and adds contribution from new modes. For RESTDP = 1, the new modal analysis (RESTMD = 0) or the d3eigv family files created elsewhere (RESTMD = 1) should exclude the modes used in previous SSD computation. This can be done by setting LFLAG (and RFLAG, if necessary), and setting a nonzero LFTEND (and

RHTEND) in *CONTROL_IMPLICIT_EIGENVALUE. The RESTDP option can also be used if the frequency range for modal analysis is divided into segments and modal analysis is performed for each frequency range separately.

6. Sometimes customers would like to add some acoustic field nodes and run BEM/FEM acoustic computation after SSD. The RESTMD and RESTDP options still work even if the number of nodes may get changed after previous modal analysis, provided that the IDs of the old nodes are not changed.
7. Damping can be prescribed in several ways:
 - a) To use a constant modal damping coefficient ζ for all the modes, define DAMPF only. LCDMP, LCTYP, DMPMAS and DMPSTF are ignored.
 - b) To use mode dependent modal damping, define a load curve (*DEFINE_CURVE) and specify that if the abscissa value defines the frequency or mode number by LCTYP. DMPMAS and DMPSTF are ignored.
 - c) To use Rayleigh damping, define DMPMAS (α) and DMPSTF (β) and keep DAMPF as 0.0, and keep LCDMP, LCTYP as 0. The damping matrix in Rayleigh damping is defined as $\mathbf{C} = \alpha\mathbf{M} + \beta\mathbf{K}$, where, \mathbf{C} , \mathbf{M} and \mathbf{K} are the damping, mass and stiffness matrices respectively.
8. NOOUT and NOTYP are used to define the nodes where velocity or acceleration are requested to be written to a binary file "bin_ssd" or other filename defined by "bem=filename" (see keyword *FREQUENCY_DOMAIN_ACOUSTIC_BEM) in command line. The velocity or acceleration data in this file can be used by BEM or FEM acoustic solver to perform a vibro-acoustic analysis. If structure nodes and acoustic boundary nodes are mismatched, the option NOTYP = -2 can be used. The velocity or acceleration data given at a structure segment set NOOUT is mapped to acoustic boundary nodes.
9. For base velocity, base acceleration or base displacement (VAD = 2, 3 or 4) excitations, the parameters NID, NTYP are not used and can be blank. The base velocity, base acceleration and base displacement cases are treated by applying inertia force to the structure.
10. For the cases with enforced motion excitation such as nodal velocity, acceleration, or displacement, the large mass method can be used to compute the SSD results. The excitation input can be given as enforced motion curves (VAD = 5, 6, 7). To use the large mass method, the user need to attach a large mass to the nodes where the enforced motion is applied by using the keyword *ELEMENT_MASS_{OPTION}, and report the large mass per node (MPN) in the keyword *CONTROL_FREQUENCY_DOMAIN. For more details, please refer to *CONTROL_FREQUENCY_DOMAIN.

11. Displacement, velocity and acceleration results are output into ASCII file NODOUT_SSD. The nodes to be output to NODOUT_SSD are specified by card *DATABASE_HISTORY_NODE. The frequencies for the nodal results in NODOUT_SSD are specified by card *DATABASE_FREQUENCY_ASCII_NODOUT_SSD. If the card *DATABASE_FREQUENCY_ASCII_NODOUT_SSD is not defined, the frequencies for the nodal results in NODOUT_SSD are same as those in D3SSD binary database, which is defined by card *DATABASE_FREQUENCY_BINARY_D3SSD.
12. Stress (and strain) results are output into ASCII file ELOUT_SSD. The solid, beam, shell and thick shell elements to be output to ELOUT_SSD are specified by the following cards:

*DATABASE_HISTORY_SOLID_{OPTION}

*DATABASE_HISTORY_BEAM_{OPTION}

*DATABASE_HISTORY_SHELL_{OPTION}

*DATABASE_HISTORY_TSHELL_{OPTION}

- The frequencies for the element stress / strain results in ELOUT_SSD are specified by card *DATABASE_FREQUENCY_ASCII_ELOUT_SSD. If the card *DATABASE_FREQUENCY_ASCII_ELOUT_SSD is not defined, the frequencies for the element stress / strain results in ELOUT_SSD are same as those in D3SSD binary database, which is defined by card *DATABASE_FREQUENCY_BINARY_D3SSD.
13. The phase angle is given in degrees in the range (-180°, 180°], for both the input decks and output databases (e.g. D3SSD, NODOUT_SSD, and ELOUT_SSD).
 14. When the FATIGUE option is present, the cumulative fatigue damage ratio due to the harmonic vibration is computed and saved in binary plot database d3ftg. The *MATERIAL_ADD_FATIGUE keyword is needed to define the S-N fatigue curve for each material.
 15. When the FRF option is present, LS-DYNA calculates the steady state dynamic response due to unit load spectrum. Numerically it is equivalent to Frequency Response Function (FRF). In this case, LC1 and LC2 are not used and can be blank. LS-DYNA generates unit load spectrum, according to the excitation location, the excitation degree-of-freedom and the excitation type defined by NID, NTYP, DOF and VAD in Card 4. This is useful if the user is interested in getting FRF fringe plot at some frequencies, or if the user would like to get the stress (and strain) FRF results.

*HOURLASS

Purpose: Define hourglass and bulk viscosity properties which are referenced via HGID in the *PART command. Properties specified here, when invoked for a particular part, override those in *CONTROL_HOURLASS and *CONTROL_BULK_VISCOSITY.

An additional option **TITLE** may be appended to *HOURLASS keywords. If this option is used then an additional line is read for each section in 80a format which can be used to describe the section. At present, the title serves no purpose other than to perhaps lend clarity to input decks.

VARIABLE**DESCRIPTION**

HGID

Hourglass ID. A unique number or label must be specified. This ID is referenced by HGID in the *PART command.

*HOURGLASS

| VARIABLE | DESCRIPTION |
|-----------------|--|
| IHQ | <p>Hourglass control type. For solid elements six options are available. For quadrilateral shell and membrane elements the hourglass control is based on the formulation of Belytschko and Tsay, i.e., options 1-3 are identical, and options 4-5 are identical:</p> <p>EQ.0: see remark 9,</p> <p>EQ.1: standard LS-DYNA viscous form,</p> <p>EQ.2: Flanagan-Belytschko viscous form,</p> <p>EQ.3: Flanagan-Belytschko viscous form with exact volume integration for solid elements,</p> <p>EQ.4: Flanagan-Belytschko stiffness form,</p> <p>EQ.5: Flanagan-Belytschko stiffness form with exact volume integration for solid elements.</p> <p>EQ.6: Belytschko-Bindeman [1993] assumed strain co-rotational stiffness form for 2D and 3D solid elements only.</p> <p>EQ.7: Linear total strain form of type 6 hourglass control. (See remark 6 below).</p> <p>EQ.8: Activates the full projection warping stiffness for shell formulations 16 and -16, and is the default for these formulations. A speed penalty of 25% is common for this option.</p> <p>EQ.9: Puso [2000] enhanced assumed strain stiffness form for 3D hexahedral elements.</p> <p>EQ.10: Cosserat Point Element (CPE) developed by Jabareen and Rubin [2008] and Jabareen et.al. [2013], see *CONTROL_HOURGLASS.</p> |

A discussion of the viscous and stiffness hourglass control for shell elements follows at the end of this section..

| VARIABLE | DESCRIPTION |
|----------|---|
| QM | Hourglass coefficient. Values of QM that exceed 0.15 may cause instabilities for brick elements used with forms IHG = 0 to 5 and all the IHG forms applicable to shell elements. The stiffness forms can stiffen the response especially if deformations are large and therefore should be used with care. For the shell and membrane elements QM is taken as the membrane hourglass coefficient, the bending as QB, and warping as QW. These coefficients can be specified independently, but generally, $QM = QB = QW$, is adequate. For type 6 solid element hourglass control, see remark 4 below. For hourglass type 9, see Remark 8. |
| IBQ | Not used. Bulk viscosity is always on for solids. Bulk viscosity for beams and shells can only be turned on using the variable TYPE in *CONTROL_BULK_VISCOSITY; however, the coefficients can be set using Q1 and Q2 below. |
| Q1 | Quadratic bulk viscosity coefficient. |
| Q2 | Linear bulk viscosity coefficient. |
| QB | Hourglass coefficient for shell bending. The default: $QB = QM$. (See Remark 4). |
| VDC | Viscous damping coefficient to help suppress hourglass modes. VDC only applies to type 1 solids with type 6 or 7 hourglass control and to tshell formulations 5 and 6. VDC is a unitless coefficient in which $VDC = 1.0$ corresponds to critical damping. |
| QW | Hourglass coefficient for shell warping. The default: $QB = QW$. |

Remarks:

1. Viscous hourglass control is recommended for problems deforming with high velocities. Stiffness control is often preferable for lower velocities, especially if the number of time steps are large. For solid elements the exact volume integration provides some advantage for highly distorted elements.
2. For automotive crash the stiffness form of the hourglass control with a coefficient of 0.05 is preferred by many users.
3. Bulk viscosity is necessary to propagate shock waves in solid materials. Generally, the default values are okay except in problems where pressures are very high, larger values may be desirable. In low density foams, it may be

*HOURLGLASS

necessary to reduce the viscosity values since the viscous stress can be significant. It is not advisable to reduce it by more than an order of magnitude.

4. Type 6 hourglass control is for 2D and 3D solid elements only. Based on elastic constants and an assumed strain field, it produces accurate coarse mesh bending results for elastic material when $QM = 1.0$. For plasticity models with a yield stress tangent modulus that is much smaller than the elastic modulus, a smaller value of QM (0.001 to 0.1) may produce better results. For foam or rubber models, larger values (0.5 to 1.0) may work better. For any material, keep in mind that the stiffness is based on the elastic constants, so if the material softens, a QM value smaller than 1.0 may work better. For anisotropic materials, an average of the elastic constants is used. For fluids modeled with null material, type 6 hourglass control is viscous and is scaled to the viscosity coefficient of the material (see *MAT_NULL).
5. In part, the computational efficiency of the Belytschko-Lin-Tsay and the under integrated Hughes-Liu shell elements are derived from their use of one-point quadrature in the plane of the element. To suppress the hourglass deformation modes that accompany one-point quadrature, hourglass viscous or stiffness based stresses are added to the physical stresses at the local element level. The discussion of the hourglass control that follows pertains to all one point quadrilateral shell and membrane elements in LS-DYNA.

The hourglass shape vector τ_I is defined as

$$\tau_I = h_I - (h_I \hat{x}_{aJ}) B_{aI}$$

where, \hat{x}_{aJ} are the element coordinates in the local system at the I th element node, B_{aI} is the strain displacement matrix, and hourglass basis vector is:

$$h = \begin{bmatrix} +1 \\ -1 \\ +1 \\ -1 \end{bmatrix}$$

is the basis vector that generates the deformation mode that is neglected by one-point quadrature. In the above equations and the remainder of this subsection, the Greek subscripts have a range of 2, e.g., $\hat{x}_{aI} = (\hat{x}_{1I}, \hat{x}_{2I}) = (\hat{x}_I, \hat{y}_I)$.

The hourglass shape vector then operates on the generalized displacements to produce the generalized hourglass strain rates

$$\begin{aligned} \dot{q}_\alpha^M &= \tau_I \hat{v}_{\alpha I} \\ \dot{q}_\alpha^B &= \tau_I \hat{\theta}_{\alpha I} \\ \dot{q}_3^W &= \tau_I \hat{v}_{zI} \end{aligned}$$

where the superscripts M, B, and W denote membrane, bending, and warping modes, respectively. The corresponding hourglass stress rates are then given by

$$\begin{aligned}\dot{Q}_\alpha^M &= \frac{QM \times EtA}{8} B_{\beta I} B_{\beta I} \dot{q}_\alpha^M \\ \dot{Q}_\alpha^B &= \frac{QB \times Et^3 A}{192} B_{\beta I} B_{\beta I} \dot{q}_\alpha^B \\ \dot{Q}_3^W &= \frac{QW \times \kappa G t^3 A}{12} B_{\beta I} B_{\beta I} \dot{q}_3^B\end{aligned}$$

where t is the shell thickness. The hourglass coefficients: QM, QB, and QW are generally assigned values between 0.05 and 0.10.

Finally, the hourglass stresses which are updated using the time step, Δt , from the stress rates in the usual way, that is,

$$Q^{n+1} = Q^n + \Delta t \dot{Q}$$

and the hourglass resultant forces are then

$$\begin{aligned}\hat{f}_{\alpha I}^H &= \tau_I Q_\alpha^M \\ \hat{m}_{\alpha I}^H &= \tau_I Q_\alpha^B \\ \hat{f}_{3I}^H &= \tau_I Q_3^W\end{aligned}$$

where the superscript H emphasizes that these are internal force contributions from the hourglass deformations.

6. IHQ = 7 is a linear total strain formulation of the Belytschko-Bindeman [1993] stiffness form for 2D and 3D solid elements. This linear form was developed for visco-elastic material and guarantees that an element will spring back to its initial shape regardless of the severity of deformation.
7. The default value for QM is 0.1 unless superseded by a nonzero value of QH in *CONTROL_HOURGLASS. A nonzero value of QM supersedes QH.
8. Hourglass type 9 is available for hexahedral elements and is based on physical stabilization using an enhanced assumed strain method. In performance it is similar to the Belytschko-Bindeman hourglass formulation (type 6) but gives more accurate results for distorted meshes, e.g., for skewed elements. If QM = 1.0, it produces accurate coarse bending results for elastic materials. The hourglass stiffness is by default based on elastic properties, hence the QM parameter should be reduced to about 0.1 for plastic materials in order not to stiffen the structure during plastic deformation. For materials 3, 18 and 24 there is the option to use a negative value of QM. With this option, the hourglass stiffness is based on the current material properties, i.e., the plastic tangent modulus, and scaled by |QM|.
9. The default value for IHQ, if not defined on *CONTROL_HOUGRGLASS is as follows:

*HOURGLASS

For shells: viscous type (1 = 2 = 3) for explicit; stiffness type (4=5) for implicit.

For solids: type 2 for explicit; type 6 for implicit.

For tshell formulation 1: type 2.

10. For implicit analysis, hourglass forms 6, 7, 9, and 10 are available for solid elements, and the stiffness form (4 = 5) is available for shells.
11. Tshell formulations 2 and 3 have 2×2 in-plane integration and therefore do not use hourglass control.
12. In the case of tshell formulation 1, there are two viscous hourglass types (IHQ = 1,2) and one stiffness type (IHQ > 2).
13. The hourglass type IHQ has no bearing on tshell formulations 5 and 6 as these formulations are based on an assumed strain field, similar to formulation 1 solids with hourglass type 6. The hourglass coefficient QM does affect the behavior of tshell formulations 5 and 6.

*INCLUDE

Purpose: The keyword *INCLUDE provides a means of reading independent input files containing model data. The file contents are placed directly at the location of the *INCLUDE line.

*INCLUDE_AUTO_OFFSET

*INCLUDE_{*OPTION*}

*INCLUDE_COMPENSATION_OPTION

*INCLUDE_MULTISCALE_SPOTWELD

*INCLUDE_TRIM

*INCLUDE_UNITCELL

***INCLUDE_{OPTION}**

Available options include:

<BLANK>

BINARY

NASTRAN

PATH

PATH_RELATIVE

STAMPED_SET

TRANSFORM

TRANSFORM_BINARY

STAMPED_PART_{*OPTION1*}_{*OPTION2*}_{*OPTION3*}*OPTION1*: SET*OPTION2*: MATRIX*OPTION3*: INVERSE

The BINARY and TRANSFORM_BINARY options specify that the initial stress file, dynain, is written in a binary format. See the keyword *INTERFACE_SPRINGBACK.

The PATH option defines a directory in which to look for the include files. The program always searches the local directory first. If an include file is not found and the filename has no path, the program will search for it in all the directories defined by *INCLUDE_PATH. Multiple paths can be defined with one *INCLUDE_PATH definition, i.e.,

```
*INCLUDE_PATH
Directory_path1
Directory_path2
Directory_path3
```

Directory paths are read until the next "*" card is encountered. A directory path can have up to 236 characters (see [Remark 3](#)).

The PATH_RELATIVE option is like the PATH option, except all directories are relative to the location of the input file. For example, if "i=/home/test/problems/input.k" is given on the command line, and the input contains

```
*INCLUDE_PATH_RELATIVE
Includes
../includes
```

then the two directories /home/test/problems/includes and /home/test/includes will be searched for include files.

The STAMPED_PART option applies only to thin shell elements and allows the plastic strain and thickness distribution of the stamping simulation to be mapped onto a part in the crash model.

1. When option 1, SET is used, the PID will be part set ID. All the parts included in this set will be considered in this mapping.
2. When option 2, MATRIX is used, translation matrix will be read directly and the orientation nodes will be ignored.
3. When option 3, INVERSE (must be used with MATRIX) is used, the matrix will be reversed first.

When STAMPED_SET is used, the target is a part set ID. Between the stamped part and the crash part, note the following points:

1. The outer boundaries of the parts do not need to match since only the regions of the crash part which overlap the stamped part are initialized.
2. Arbitrary mesh patterns are assumed.
3. Element formulations can change.
4. Three nodes on each part are used to reorient the stamped part for the mapping of the strain and thickness distributions. After reorientation, the three nodes on each part should approximately coincide.
5. The number of in plane integrations points can change.
6. The number of through thickness integration points can change. Full interpolation is used.
7. The node and element ID's between the stamped part and the crash part do not need to be unique.

The TRANSFORM option allows for node, element, and set ID's to be offset and for coordinates and constitutive parameters to be transformed and scaled.

*INCLUDE

*INCLUDE_{OPTION}

VARIABLE**DESCRIPTION**

| | |
|----------|---|
| FILENAME | File name of file to be included in this keyword file, 80 characters maximum. If the STAMPED_PART option is active, this is the dynain file containing the results from metal stamping. |
| BEAMDF | LS-DYNA beam element type. Defaults to type 2. |
| SHELLDF | LS-DYNA shell element type. Defaults to type 21. |
| SOLIDDF | LS-DYNA solid element type. Defaults to type 18. |
| PID | Part ID of crash part for remapping. |
| THICK | Thickness remap: EQ.0: map thickness EQ.1: do not map thickness EQ.2: average value inside a circle defined by RMAX |
| PSTRN | Plastic strain remap: EQ.0: map plastic strain EQ.1: do not plastic strain EQ.2: average value inside a circle defined by RMAX |
| STRAIN | Strain remap: EQ.0: map strains EQ.1: do not map strains |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| STRESS | <p>Stress tensor remap:</p> <p>EQ.0: map stress tensor and history variables</p> <p>EQ.1: do not map stress tensor, only history variables</p> <p>EQ.2: neither map stress tensor nor history variables</p> <p>EQ.-1: map stress tensor in an internal large format (binary files)</p> <p>EQ.-3: do not map stress tensor in an internal large format, only history (binary files)</p> |
| INCOUT | <p>EQ.1: to save the mapped data to a file called dyna.inc, which contains the mapped data for the part that is being mapped. This option is useful to do mapping using INCLUDE_STAMPED_PART and then save the mapped data for future use. When INCOUT is set to 2, the output file is in dynain format and the file name is dynain_xx (xx is the part or part set id); and when INCOUT is set to 3, the output file is in NASTRAN format, and the file name is: nastran_xx.</p> <p>EQ.2: to save the mapped data for the specified part (PID) to a file called dynain_PID.</p> <p>EQ.3: to save the mapped data for the specified part (PID) to a file called nastran_PID (in nastran format)</p> |
| RMAX | <p>Search radius. LS-DYNA remaps history variables from the mesh of the stamped part to the mesh of the crash part with a spatial tolerance of RMAX. If an element in the crash part lies within RMAX of the stamped part, data will be mapped to that element. If set less than 0.001, RMAX automatically assumes the default value of 20.</p> |
| N1S | First of 3 nodes needed to reorient the stamped part. |
| N2S | Second of 3 nodes needed to reorient the stamped part. |
| N3S | Third of 3 nodes needed to reorient the stamped part. |
| N1C | First of 3 nodes needed to reorient the crash model part. |
| N2C | Second of 3 nodes needed to reorient the crash model part. |
| N3C | Third of 3 nodes needed to reorient the crash model part. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| TENSOR | Tensor remap: EQ.0: map tensor data from history variables. (See Remark 4.) EQ.1: do not map tensor data from history variables |
| THKSCL | Thickness scale factor. |
| R11, R12, R33 | Components of the transformation matrix. |
| XP, YP, ZP | Translational distance. |
| ISYM | Symmetric switch EQ.0: no symmetric mapping EQ.1: yz plane symmetric mapping EQ.2: zx plane symmetric mapping EQ.3: zx and yz planes symmetric mapping EQ.4: user defined symmetric plane mapping |
| IAFTER | Mirroring sequence switch EQ.0: generate a symmetric part before transformation EQ.1: generate a symmetric part after transformation |
| PERCELE | Percentage of elements that should be mapped to proceed (default = 0); otherwise an error termination occurs. See Remark 6. |
| IORTHO | Location of the material direction cosine in the array of history variables of an orthotropic material. See Remark 5. |
| ISRCOUT | Optional output of stamped part after transformation(s) EQ.0: no output is written NE.0: keyword output file “srcmsh_<ISRCOUT>” is created |
| X01, Y01, Z01 | First point in the symmetric plane (required if ISYM.NE.0) |
| X02, Y02, Z02 | Second point in the symmetric plane |
| X03, Y03, Z03 | Third point in the symmetric plane |
| IDNOFF | Offset to node ID. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| IDEOFF | Offset to element ID. |
| IDPOFF | Offset to part ID, nodal rigid body ID, constrained nodal set ID, Rigidwall ID, and *DATABASE_CROSS_SECTION. |
| IDMOFF | Offset to material ID and equation of state ID. |
| IDSOFF | Offset to set ID. |
| IDFOFF | Offset to function ID, table ID, and curve ID. |
| IDDOFF | Offset to any ID defined through *DEFINE except the FUNCTION, TABLE, and CURVE options (see IDFOFF). |
| IDROFF | Used for all offsets except for those listed above. |
| PREFIX | Prefix added to the beginning of the titles/heads defined in the keywords (like *MAT, *PART, *SECTION, *DEFINE, for examples) of the included file. A dot, ".", is automatically added between the prefix and the existing title. |
| SUFFIX | Suffix added to the end of the titles/heads defined in the keywords of the included file. A dot, ".", is automatically added between the suffix and the existing title. |
| FCTMAS | Mass transformation factor. For example, FCTMAS = 1000. When the original mass units are in tons and the new unit is kg. |
| FCTTIM | Time transformation factor. For example, FCTTIM=.001 when the original time units are in milliseconds and the new time unit is seconds. |
| FCTLEN | Length transformation factor. |
| FCTTEM | Temperature transformation factor consisting of a four character flag: FtoC (Fahrenheit to Centigrade), CtoF, FtoK, KtoF, KtoC, and CtoK. |
| INCOUT1 | Set to 1 for the creation of a file, DYNA.INC, which contains the transformed data. The data in this file can be used in future include files and should be checked to ensure that all the data was transformed correctly. |
| TRANID | Transformation ID, if 0 no transformation will be applied. See the input DEFINE_TRANSFORMATION. |

Remarks:

1. **Scalability.** To make the input file easy to maintain, this keyword allows the input file to be split into subfiles. Each subfile can again be split into sub-subfiles and so on. This option is beneficial when the input data deck is very large. Consider the following example:

```
*TITLE
full car model
*INCLUDE
carfront.k
*INCLUDE
carback.k
*INCLUDE
occupantcompartment.k
*INCLUDE
dummy.k
*INCLUDE
bag.k
*CONTACT
:
*END
```

Note that the command *END terminates the include file.

The carfront.k file can again be subdivided into rightrail.k, leftrail.k, battery.k, wheel-house.k, shotgun.k, etc.. Each *.k file can include nodes, elements, boundary conditions, initial conditions, and so on.

```
*INCLUDE
rightrail.k
*INCLUDE
leftrail.k
*INCLUDE
battery.k
*INCLUDE
wheelhouse.k
*INCLUDE
shotgun.k
:
*END
```

2. **Reorienting the Result of a Stamping Simulation for STAMPED_PART option.** When defining *INCLUDE_STAMPED_PART the target mesh must be read in before the include stamped part.

N1S, N2S, N3S, N1C, N2C, and N3C are used for transforming the stamped part to the crash part, such that it is in the same position as the crash part. If the stamped part is in the same position as the crash part then N1S, N2S, N3S, N1C,

N2C, N3C can all be set to 0. Note: If these 6 nodes are input as 0, LS-DYNA will not transform the stamped part.

When symmetric mapping is used (ISYM is not zero), the three points should not be in one line.

If ISYM = 0, 1, 2, or 3, only the first point (X01,Y01, Z01) is needed

If ISYM = 4, all the three points are needed

3. **Path Length Limitations.** Filenames and pathnames are limited to 236 characters spread over up to three 80 character lines. When 2 or 3 lines are needed to specify the filename or pathname, end the preceding line with "␣+" (space followed by a plus sign) to signal that a continuation line follows. Note that the "␣+" combination is, itself, part of the 80 character line; hence the maximum number of allowed characters is $78 + 78 + 80 = 236$.
4. **Mapping Material Data for Springback for STAMPED_PART option.** Certain material models (notably Material 190) have tensor data stored within the history variables. Within material subroutines this data is typically stored in element local coordinate systems. In order to properly map this information between models it is necessary to have the tensor data present on the *INITIAL_STRESS_SHELL card and have it stored in global coordinates. During mapping the data is then converted into the local coordinate system of the crash mesh. This data can be dumped into the dynain file that is created at termination time if the parameter FTENSR is set to 0 on the *INTERFACE_-SPRINGBACK_DYNA3D card. Currently, the only material model that supports mapping of element history tensor data is Material 190.
5. **IORTHO.** If IORTHO is set, correct mapping between non-matching meshes is invoked for the directions of orthotropic materials. A list of appropriate values for several materials is given here:

IORTHO.EQ.1: materials 23, 122, 157, 234

IORTHO.EQ.3: materials 22, 33, 36, 133, 189, 233, 243

IORTHO.EQ.4: material 59

IORTHO.EQ.6: materials 58, 104, 158

IORTHO.EQ.8: materials 54, 55

IORTHO.EQ.9: material 39

IORTHO.EQ.10: material 82

IORTHO.EQ.13: materials 2, 86, 103

6. **Mapping Mismatch with STAMPED_PART option.** Sometimes during mapping the two meshes (stamp mesh and crash mesh) do not fit exactly and therefore not all elements of the new mesh get results from the old mesh. Information about the total number of crash elements which are / are not mapped is given in the message file. By default (PERCELE=0), the calculation continues even with zero number of mapped elements. With PERCELE>0 the percentage of minimum number of elements can be defined, which have to be mapped. If a percentage less than PERCELE is mapped, calculation stops with an error termination.

7. **NASTRAN Option.** The transformed LS-Dyna deck for *INCLUDE_NASTRAN will be automatically written to file DYNA.INC.

***INCLUDE_AUTO_OFFSET_{OPTION}**

Purpose: This particular *INCLUDE keyword offsets node and element IDs to avoid duplication during stamping simulations. In a single process stamping simulations the rigid tools often undergo several iterations of modifications, and the node or element IDs comprising the new tools sometimes conflict with other parts of the model. In process simulation, the IDs of later tools may overlap the IDs of the earlier tools or the sheet blank, which make it difficult to automate the process simulation. This keyword automatically checks for and offsets consecutively the duplicate IDs. Note without the option USER below, solid element IDs will not be offset. The *CONTROL_FORMING_-MAXID keyword is related.

Available option includes: Available options include:

<BLANK>

USER

The USER option allows user to specify the starting IDs of the nodes and elements for the included file. It works on solid elements, beams, and the sheet blank with stress and strain information.

Card 1. This card is included if and only if the option is <BLANK>.

| | | | | | | | | |
|----------|----------|---|---|---|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | FILENAME | | | | | | | |
| Type | C | | | | | | | |

Card 2. This card is included if and only if the USER option is used.

| | | | | | | | | |
|----------|---------|----------|---|---|---|---|---|---|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | NOFFSET | NEOFFSET | | | | | | |
| Type | I | I | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| FILENAME | File name to be included. |
| NOFFSET | Starting node ID of the include file to be offset. |
| NEOFFSET | Starting element ID of the include file to be offset. |

***INCLUDE_AUTO_OFFSET (without option):**

This keyword can be used to offset element and node IDs of the tooling. *The keyword will not offset IDs of meshes with initial stress and strain information.* As such, sheet blank (including dynain file) should always be included first using the *INCLUDE keyword, followed by *INCLUDE_AUTO_OFFSET to offset tooling mesh IDs which do not have stress and strain information.

Incoming element and node IDs of the tooling mesh files such as the punch, die, and binder, could be overlapped with each other, or overlapped with those on the sheet blank. Multiple *INCLUDE_AUTO_OFFSET can be used to include punch, die, binder separately, if desired. For example, four different components of the tooling, upper die, lower punch, binder and gage pins can be included and their element and node IDs properly offset after those of a gravity-loaded sheet blank:

```
*INCLUDE
gravity.dynain
*INCLUDE_AUTO_OFFSET
upperdie.k
*INCLUDE_AUTO_OFFSET
lowerpunch.k
*INCLUDE_AUTO_OFFSET
binder.k
*INCLUDE_AUTO_OFFSET
pins.k
```

All of the included meshes can have conflicting mesh IDs starting from "1". Mesh IDs will be offset and reordered in the order of the tool inclusion using *INCLUDE_AUTO_OFFSET. Included tool files whose mesh IDs do not overlap with those on either the blank or other tools will not be offset or reordered. In many circumstances this feature allows the user to bypass the metal forming GUI when updating just one or two tooling pieces.

***INCLUDE_AUTO_OFFSET_USER:**

This option gives user more control on the starting mesh IDs of the included file. The following example shows the offsets of included files, upper.k, lower.k, binder.k, pins.k, and formed.dynain (sheet blank), with starting node and element IDs of 1000000, 2000000, 3000000, 4000000, and 5000000, respectively. Note this option allows for offset of the sheet blank with stress and strain information, and of solid and beam elements.

```
*INCLUDE_AUTO_OFFSET_USER
./upper.k
1000000, 1000000
*INCLUDE_AUTO_OFFSET_USER
./lower.k
2000000, 2000000
*INCLUDE_AUTO_OFFSET_USER
./binder.k
3000000, 3000000
*INCLUDE_AUTO_OFFSET_USER
./pins.k
4000000, 4000000
```

```
*INCLUDE_AUTO_OFFSET_USER  
./formed.dynain  
5000000, 5000000
```

Revision information:

This feature is available in SMP and MPP in LS-DYNA Dev 92417. Dev 117818 extends the keyword to beams (used to model draw beads, for example). The option USER is available in Dev 123467, and works on solids and beams.

***INCLUDE_COMPENSATION_{OPTION}**

Purpose: This group of keywords allow for the inclusion of stamping die geometry information for springback compensation. In addition, trim curves from the target geometry can be included for mapping onto the intermediate compensated tool geometry, which can be used for the next compensation iteration. Furthermore, compensation can be done for a localized tool region. These keywords must be used together with *INTERFACE_COMPENSATION_3D, which replaces *INTERFACE_COMPENSATION_NEW as of Revision 115517.

Options available include:

BLANK_BEFORE_SPRINGBACK
BLANK_AFTER_SPRINGBACK
DESIRED_BLANK_SHAPE
COMPENSATED_SHAPE
CURRENT_TOOLS
TRIM_CURVE
CURVE
ORIGINAL_DYNAIN
SPRINGBACK_INPUT
COMPENSATED_SHAPE_NEXT_STEP
SYMMETRIC_LINES
ORIGINAL_RIGID_TOOL
NEW_RIGID_TOOL
ORIGINAL_TOOL
UPDATED_BLANK_SHAPE
UPDATED_RIGID_TOOL
BEFORE_SPRINGBACK

| VARIABLE | DESCRIPTION |
|-----------------|--|
| FILENAME | <p>For options below, input the name of the keyword files containing nodes and elements information, with adaptive constraints if exist. Currently all sheet blanks must have the same numbers of nodes and elements.</p> <p>BLANK_BEFORE_SPRINGBACK, BLANK_AFTER_SPRINGBACK, DESIRED_BLANK_SHAPE, COMPENSATED_SHAPE, CURRENT_TOOLS, COMPENSATED_SHAPE_NEXT_STEP</p> <p>For option ORIGINAL_DYNAIN, input the dynain file name from LS-DYNA simulation (for example, trimmed panel from ITER0 baseline simulation) which contains model information, adaptive constraints, stress and strain tensor information. This keyword is to be used in conjunction with *INTERFACE_COMPENSATION_NEW_ACCELERATOR.</p> <p>For option SPRINGBACK_INPUT, give the file name of springback simulation input deck for the baseline ITER0 simulation. This keyword is to be used in conjunction with *INTERFACE_COMPENSATION_NEW_ACCELERATOR.</p> <p>For option TRIM_CURVE, input the name of the keyword file containing x, y, z coordinates as defined using keyword *DEFINE_CURVE_TRIM_3D (only TCTYPE = 0, or 1 is supported). This option is used to map the trim curve to the new, compensated tooling mesh for next iterative simulation.</p> <p>For option CURVE, input the name of the keyword file containing x, y, z coordinates of two curves defining the compensation zone, using keywords: *DEFINE_CURVE_COMPENSATION_CONSTRAINT_BEGIN, and, *DEFINE_CURVE_COMPENSATION_CONSTRAINT_END. This option is for compensation of localized tooling areas.</p> <p>All foregoing keyword options are used together with *INTERFACE_COMPENSATION_NEW.</p> |

| VARIABLE | DESCRIPTION |
|----------|---|
| | <p>For options ORIGINAL_RIGID_TOOL and NEW_RIGID_TOOL, input the file names of the keyword file containing meshes of the rigid tools. This option is used to smooth distorted meshes of localized tool surfaces. These keyword options are used together with *INTERFACE_COMPENSATION_NEW_LOCAL_SMOOTH.</p> |
| | <p>For option ORIGINAL_TOOL, input the file name of the original tool (without any compensation) mesh containing nodes and elements information in keyword format. This option allow the use of the original tool mesh, which is of higher quality, in the iterative compensation runs, to minimize the tool surface mesh distortion in the addendum and binder areas of the compensated tool (see Remarks). These keyword options are used together with *INTERFACE_COMPENSATION_NEW.</p> |
| | <p>For options UPDATED_BLANK_SHAPE, and UPDATED_RIGID_TOOL, input the respective mesh information in keyword format. The updated blank shape is the blank formed (or trimmed) shape based on the new tool (die) geometry. These options allow for updating of compensated tool shape for small part shape changes, without the need to go through a full-blown iterative compensation loop again (See Remark 13). The options are used together with *INTERFACE_COMPENSATION_NEW_PART_CHANGE, among others.</p> |
| | <p>For option BEFORE_SPRINGBACK, input the “dynain” file from a forming simulation; the varied, non-homogenous thickness of the sheet blank will be used to change the uniform tool gap. It is used together with *INTERFACE_THICKNESS_CHANGE_COMPENSATION. See BEFORE_SPRINGBACK for details.</p> |
| | <p>For option TRIM_NODE, input the file name which includes a list of nodes that forms the trim curves on the rigid tools. This file can be generated from *INTERFACE_COMPENSATION_3D_REFINE_RIGID. See more details in TRIM_NODE.</p> |
| SYMID | ID of the symmetric condition being defined. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| SYMXY | Code defining symmetric boundary conditions: EQ.1: symmetric about y -axis. EQ.2: symmetric about x -axis. |
| X0, Y0 | Coordinates of a point on the symmetric plane. |
| UFLAG | A flag to maintain tangency. Set to 1 to maintain tangency between compensated and uncompensated parts of the tool, and to maintain tangential transition off the rigid tool area at the trim curves to the addendum part of the tool. See Remark 16 . |

Default Filenames:

| Keyword Option | Default Filename |
|---------------------|------------------|
| UPDATED_BLANK_SHAPE | updatedpart.tmp |
| UPDATED_RIGID_TOOL | newrigid.tmp |
| TRIM_NODE | bndnd0.tmp |

About Various Options:

This group of keywords is used in conjunction with *INTERFACE_COMPENSATION_NEW, to compensate stamping tool shapes for springback with an iterative method. The method approaches the final target design intent from two opposite directions from iteration to iteration. A typical successful compensation requires about 4 to 6 iterations.

1. **BLANK_BEFORE_SPRINGBACK.** When the option BLANK_BEFORE_SPRINGBACK is used, the included file is the mesh information in keyword format in the first state (from d3plot) of the springback simulation, or the "dynain" file after trimming (before springback and with no mesh coarsening). The default file name is "blank0.tmp".
2. **BLANK_AFTER_SPRINGBACK.** When the option BLANK_AFTER_SPRINGBACK is used, the included file is the "dynain" file after springback, or the last state mesh (from d3plot) of the springback. The default file name is "spbk.tmp".
3. **DESIRED_BLANK_SHAPE.** When the option DESIRED_BLANK_SHAPE is used, the included file is the "dynain" file after trimming in the first iteration.

This file never changes in all subsequent iterative compensation. The file name default is "reference0.dat".

4. **COMPENSATED_SHAPE.** When the option COMPENSATED_SHAPE is used, the included file for the first iteration, is a "dynain" file, same as in the option DESIRED_BLANK_SHAPE; and for the following compensation iterations, this file is obtained from the file "disp.tmp" generated as an output file during the previous compensation iteration. The default file name is "reference1.dat".
5. **CURRENT_TOOLS.** When the option CURRENT_TOOLS is used, the included file is the file containing the tool mesh in the keyword format. This is the tool mesh from the last compensation run and used for the current forming simulation. The draw bead nodes have to be included in this file so that they will be modified together with the rigid tools. The default file name is "rigid.tmp", and if the file is named as "rigid0.tmp" the elements of the tools get refined along the outline of the part.
6. **TRIM_CURVE.** When the option TRIM_CURVE is used, trim curves off the current tools are mapped onto the compensated tools for the trimming operation in the next iteration.

If the trimming simulation uses the IGES format trim curves, a new file "geocur.trm" will be generated at the end of the trimming simulation. The file basically contains XYZ data of the trim curves in keyword *DEFINE_CURVE_TRIM_{OPTIONS}, which is used for the compensation run. Note that the variable TCTYPE in the keyword must be set to "0" (or "1") for the compensation. Length of lines everywhere in the compensated part are calculated according to springback amounts (including the die expansion factors, therefore no die expansion needs to be included in the NC machining of the compensated tooling). These mapped trim curves can be used for die development on the compensated tools and for laser trimming of stamped panels. Procedures outline in keyword manual pages *INTERFACE_BLANKSIZE can be followed to convert in *LS-PrePost* IGES file of the trim curves to XYZ format (and vice versa) used in this keyword.

In an example keyword input shown below, the file name for this option is trimcurves.k. The format is in XYZ format, written with *LS-PrePost*:

```
*DEFINE_CURVE_TRIM_3D
$#   tcid   tctype   tflg   tdir   tctol   toln   nseed
      1116       1       1       tdir   0.100       1
$#           cx           cy           cz
      178.05170       -326.24771       51.924496
      177.77397       -301.90869       50.288792
      177.29764       -265.39716       48.594341
...

```

7. **CURVE.** When the option CURVE is used, it allows for die face compensation of a local region in a stamping die. This option is used in conjunction with two more keywords defining two enclosed curves that form the compensation zone in position coordinates x, y, z : *DEFINE_CURVE_COMPENSATION_CONSTRAINT_BEGIN, and *DEFINE_CURVE_COMPENSATION_CONSTRAINT_END. Detailed usage of these two keywords is available in the related manual pages.
8. **ORIGINAL_DYNAIN, and SPRINGBACK_INPUT.** These options are used together with keyword *INTERFACE_COMPENSATION_NEW_ACCELERATOR, for a springback compensation with a faster convergence rate and a simplified user interface. For detailed usage, please refer to the manual pages under *INTERFACE_COMPENSTION_{OPTION}. Here a complete keyword input is provided:

```
*KEYWORD
*INTERFACE_COMPENSATION_NEW_ACCELERATOR
$  ISTEPS      TOLX      TOLY      TOLZ      OPTION
   3          0.20      0.20      0.2       1
*INCLUDE_COMPENSATION_ORIGINAL_DYNAIN
./case20trimmed.dynain
*INCLUDE_COMPENSATION_SPRINGBACK_INPUT
./spbk.dyn
*END
```

9. **COMPENSATED_SHAPE_NEXT_STEP.** The option enables compensation of tools for the next die process. It is used in conjunction with keyword *INTERFACE_COMPENSATION_NEW_MULTI_STEPS, which is discussed in the corresponding manual pages. Here a complete input deck is given below:

```
*KEYWORD
*INTERFACE_COMPENSATION_NEW_MULTI_STEPS
$-----1-----2-----3-----4-----5-----6-----7-----8-----
-8

*END
```

10. **SYMMTRIC_LINES.** The option applies to compensation Methods 7 and 8, as discussed in *INTERFACE_COMPENSATION_NEW. In a complete keyword input example below, part set ID 1 is being compensated with symmetric

boundary condition about x -axis. The symmetric plane passes a point with coordinates of $x = 101.5$, and $y = 0.0$.

11. **ORIGINAL_RIGID_TOOL, and NEW_RIGID_TOOL.** These options are used together with `*INTERFACE_COMPENSATION_NEW_LOCAL_SMOOTH`, and `*SET_NODE_LIST_SMOOTH`, to smooth local areas of distorted meshes of a tooling surface. Details can be found in the manual pages for `*INTERFACE_COMPENSATION_NEW_LOCAL_SMOOTH`.
12. **ORIGINAL_TOOL.** The option is used to obtain a smoother mesh for the addendum and binder region for the current compensation, using the original tool mesh (of better quality) instead of the last compensated tool mesh (maybe distorted). This reduces the accumulative error in mesh extrapolation outside of the trim lines. Details can be found in the manual pages for `*INTERFACE_COMPENSATION_NEW`.
13. **UPDATED_BLANK_SHAPE, and UPDATED_RIGID_TOOL.** These options calculate a new compensated tool shape according to the updated blank shape, thus eliminating the need to go through a full-blown iterative compensation loop again. Note that these options are intended only for small part changes that do not substantially affect the amount of springback. More details can be found in the manual pages for `*INTERFACE_COMPENSATION_NEW_PART_CHANGE`.

14. **BEFORE_SPRINGBACK.** This option allows you to input a “dynain” file from a forming simulation; the varied, non-homogeneous thickness of the sheet blank will be used to change the uniform gap of a stamping tool set, which is input using the option CURRENT_TOOLS. This is typically used in hot stamping simulation, where contact is required between all upper/lower tools and the sheet blank. More details can be found in the manual pages under *INTERFACE_THICKNESS_CHANGE_COMPENSATION.
15. **TRIM_NODE.** This option requires a file (default file name “bndnd0.tmp”) containing a list of nodes (in type I10 per line) along the part trim curves to ensure tangency during compensation. The file can be generated using *INTERFACE_COMPENSATION_3D_REFINE_RIGID, where the original tool mesh and trim curves are input to obtain a refined tool mesh, where nodes will also be aligned with the trim curves, which ensures subsequent compensation of the tool to extend all the way to the trim curves. More detailed usage can be found in the manual pages for *INTERFACE_COMPENSATION_3D.
16. **TANGENT_CONSTRAINT.** This option is used to maintain tangency in the part boundary (along trim curves) between compensated and uncompensated areas of the tool, as such, it typically applies to Method 7. The option also makes tangential transition off the rigid tool area at the trim curves to the addendum part of the tool. This keyword was replaced by the TANGENT variable under *INTERFACE_COMPENSATION_3D.

Full Example of a Springback Compensation:

The following example is for compensation of a localized area, defined by the file curves.k. Trim lines are mapped onto the new compensated rigid tool, with trimcurves.k. Both files which were generated by *LS-PrePost* 4.0 are in the “XYZ format”. A detailed explanation of each keyword is given in the manual pages related to *INTERFACE_COMPENSATION_3D.

|----------|----------|---|---|---|---|---|---|---|
| Variable | FILENAME | | | | | | | |
| Type | C | | | | | | | |
| Default | none | | | | | | | |

VARIABLE

DESCRIPTION

TYPE

TYPE for this multiscale spot weld. This type is used in the keyword *DEFINE_SPOTWELD_MULTISCALE. Any unique integer will do.

FILENAME

Name of file from which to read the spot weld definition.

Remarks:

This capability is available *only* in the MPP version of LS-DYNA.

With the multiscale spot weld feature heuristic spot weld models are replaced with zoomed-in geometrically and constitutively correct continuum models, which, in turn are coupled to the large-scale calculation without reducing the time step. In some respects, multiscale models are similar to the "hex spot weld assemblies," capability but more general in terms of their geometry. Because the spot weld models are run in a separate process, they can run at a much smaller time step without slowing down the rest of the simulation. A brief outline of their use looks like this:

- The user creates one (or more) detailed models of their spot welds, and includes these definitions into their model using the keyword `*INCLUDE_MULTISCALE_SPOTWELD`
- The user indicates which beam (or hex assembly) spot welds should be coupled to these models via the keyword `*DEFINE_SPOTWELD_MULTISCALE`
- When MPP-DYNA is started, a special (MPI dependent) invocation is required in order to run in a “multiple program” mode. Effectively, two separate instances of MPP-DYNA are started together, one to run the full model and a separate instance to run the spot welds.
- As the master process runs, each cycle it communicates to the slave process deformation information for the area surrounding each coupled spot weld. The slave process imposes this deformation on the detailed spot welds, computes a failure flag for each, and communicates this back to the master process.
- The coupled spot welds in the master process have their failure determined solely by these failure flags.

The file referred to on the `*INCLUDE_MULTISCALE_SPOTWELD` card should contain one generic instance of a detailed spot weld. For each coupled spot weld in the main model, a specific instance of this spot weld will be generated which is translated, rotated, and scaled to match the spot weld to which it is coupled. In this way, many spot welds can be coupled with only a single `*INCLUDE_MULTISCALE_SPOTWELD`. The included file should contain everything required to define the spot weld, such as `*MAT` and `*PART` definitions, any required `*DEFINE_CURVE`s, etc., as well as `*NODE` and `*ELEMENT` definitions. In order for the translation and scaling to work properly there are some assumptions made about the spot weld model:

- It consists entirely of solid elements.
- The z-axis is aligned with the coupled spot weld in the main model, with $z = 0$ and $z = 1$ at the two ends of the spot weld.
- The cross sectional area of the spot weld in the xy plane is equal to 1.
- That portion of the “top” and “bottom” of the spot weld that are coupled are identified using a single `*SET_NODE_LIST` card.
- One `*BOUNDARY_COUPLED` card referencing the `*SET_NODE_LIST` of the boundary nodes is required. It must specify a coupling type of 2 and a coupling program of 1.
- The spot weld model does not support `*INCLUDE` cards.

Failure of the fine model is determined topologically. Any element of the spot weld having all four nodes of one of its faces belonging to the `*SET_NODE_LIST` of tied nodes is classified as a “tied” element. The “tied” elements are partitioned into two disjoint sets: the “top,” and “bottom”. When there is no longer a complete path from any “top” to any “bottom” element (where a “path” passes through non-failed elements

that share a common face), then the spot weld has failed. Note that this places some restrictions on the *SET_NODE_LIST and element geometry, namely that some “tied” elements exist, and the set of “tied” elements consists of exactly two disjoint subsets.

The specifics of launching a multi-program MPI program are installation dependent. But the idea behind running a coupled model is that you want to run one set of MPI ranks as if you were running a normal MPP-DYNA job, such as:

```
mpirun -np 4 mppdyna i=input.k memory=200m p=pfile
```

and a second set with just the command line argument “slave” (no input file):

```
mpirun -np 4 mppdyna slave memory=100m p=pfile
```

The main instance knows to look for the slave (because of the presence of the *INCLUDE_MULTISCALE_SPOTWELD card), and will run the main model. The “slave” instance will run all the detailed spot weld models. Due to the nature of the coupling, the main model cannot progress when the detailed spot welds are being processed, nor can the detailed spot welds run while the main model is being computed. From a processor efficiency standpoint, it therefore makes sense to run as many slave processes as master processes, and run them on the same CPUs, so that each processing core has one slave and one master process running on it. But you don’t have to – the processes are independent and you can have any number of either.

***INCLUDE_TRIM**

Purpose: The naive procedure to trim a part imported using the *INCLUDE keyword involves: (1) including the part using *INCLUDE; (2) designating the part for trimming using *CONTROL_FORMING_TRIMMING; and (3) defining trim curves using *DEFINE_TRIM_CURVE. By replacing *INCLUDE in step (1) with this keyword, namely, *INCLUDE_TRIM, LS-DYNA is directed to filter the included part while reading in the include file (as opposed to after reading in), thereby saving memory that would otherwise be allocated to store the (immediately) discarded data.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|---|---|---|---|---|---|---|
| Variable | FILENAME | | | | | | | |
| Type | C | | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|----------|--------------------------------------|
| FILENAME | File name of the part to be trimmed. |
|----------|--------------------------------------|

General remarks:

The name of the file to be trimmed should be put into the "FILENAME" field as with the vanilla version of *INCLUDE. All information about the included part (such as stress and strain) should be in the named file (as opposed to split across several files). For example, a drawn panel from a previous simulation can be included in a current simulation for trimming as follows,

```
*INCLUDE_TRIM
Drawnpanel.dynain
*CONTROL_FORMING_TRIMMING
:
*DEFINE_CURVE_TRIM_3D
:
*CONTROL_ADAPTIVE_CURVE
:
```

This feature has been developed in conjunction with the *Ford Motor Company Research and Advanced Engineering Laboratory*, and is implemented in LS-PrePost as of version 4.0 under the metal forming application under eZ-Setup (<http://ftp.lstc.com/anonymous/outgoing/lsprepost/4.0/metalfforming/>).

This keyword, *INCLUDE_TRIM, *cannot* be used unless the included file contains stress and strain information. Namely, the "dynain" file must contain *INITIAL_STRESS_SHELL and *INITIAL_STRAIN_SHELL cards or the *INCLUDE keyword should be used instead.

For solid element trimming, the keyword `*INCLUDE_TRIM` *must* be used. In other words, the dynain file from a previous process (for example, a forming simulation) must be included in a main trim file using `*INCLUDE_TRIM` (not `*INCLUDE`). Refer to `*DEFINE_CURVE_TRIM` section for more details.

Application example:

Referring to the table below (parts courtesy of the *Ford Motor Company*), compared with `*INCLUDE` the `*INCLUDE_TRIM` keyword reduces memory requirements by more than 50%. Levels of CPU time reductions exceed in some cases 50%.

VARIABLE

DESCRIPTION

FILENAME

Name of the file containing the information of unit cell.

INPT

Type of input

EQ.0: read *NODE information from the include file and add periodic boundary conditions to the include file.

EQ.1: create a unit cell mesh with periodic boundary conditions, and output to the include file.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| OUPT | Type of output EQ.1: create a new main keyword file where the keyword *INCLUDE_UNITCELL is replaced by *INCLUDE with the include file name. |
| NEDOF | Number of extra nodal degrees of freedom (DOFs) for user-defined element. In the current implementation, the limit of NEDOF is 15. |
| DX | Defines the x -dimension of unit cell. |
| DY | Defines the y -dimension of unit cell. |
| DZ | Defines the z -dimension of unit cell. |
| NEX | Defines number of elements along x -direction. |
| NEY | Defines number of elements along y -direction. |
| NEZ | Defines number of elements along z -direction. |
| NNPE | Defines number of nodes per element. The current implementation supports only 4-node tetrahedron or 8-node hexahedron elements. |
| NOFF | Defines offset of nodal IDs. |
| EOFF | Defines offset of elemental IDs. |
| PNM | Defines part ID. |
| CNX | Defines nodal ID of the 1 st control point for the constraint in x direction. |
| CNY | Defines nodal ID of the 2 nd control point for the constraint in y direction. |
| CNZ | Defines nodal ID of the 3 rd control point for the constraint in z direction. |
| ECNX | Defines nodal ID of extra control point for the constraint in x direction of 3 extra nodal DOFs. |
| ECNY | Defines nodal ID of extra control point for the constraint in y direction of 3 extra nodal DOFs. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| ECNZ | Defines nodal ID of extra control point for the constraint in z direction of 3 extra nodal DOFs. |

Remarks:

1. **Include File Field.** If $INPT = 0$, the geometry and discretization information for the unit cell are from the include file. In this case, the parameters in Cards 3 and 4 are ignored.
2. **Extra Degrees of Freedom.** The extra degrees of freedom (DOFs) specified by $NEDOF > 0$ are represented by extra nodes with regular x , y and z DOFs. When $NEDOF = 7$, for example, the following chart shows the mapping from the extra DOFs to the regular ones of extra nodes:

| Extra Node # | Extra DOFs | Regular DOFs |
|--------------|------------|--------------|
| 1 | 1 | x |
| | 2 | y |
| | 3 | z |
| 2 | 4 | x |
| | 5 | y |
| | 6 | z |
| 3 | 7 | x |

In this case, 3 control points for x , y , and z directions, respectively, need to be defined for each extra node.

*INITIAL

The keyword *INITIAL provides a way of initializing velocities and detonation points. The keyword control cards in this section are defined in alphabetical order:

- *INITIAL_AIRBAG_PARTICLE_POSITION
- *INITIAL_ALE_MAPPING
- *INITIAL_AXIAL_FORCE_BEAM
- *INITIAL_DETONATION
- *INITIAL_EOS_ALE
- *INITIAL_FATIGUE_DAMAGE_RATIO
- *INITIAL_FOAM_REFERENCE_GEOMETRY
- *INITIAL_GAS_MIXTURE
- *INITIAL_INTERNAL_DOF_SOLID_{*OPTION*}
- *INITIAL_LAG_MAPPING
- *INITIAL_MOMENTUM
- *INITIAL_PWP_DEPTH
- *INITIAL_STRAIN_SHELL_{*OPTION*}
- *INITIAL_STRAIN_SOLID_{*OPTION*}
- *INITIAL_STRESS_BEAM
- *INITIAL_STRESS_DEPTH
- *INITIAL_STRESS_SECTION
- *INITIAL_STRESS_SHELL_{*OPTION*}
- *INITIAL_STRESS_SOLID
- *INITIAL_STRESS_TSHELL
- *INITIAL_TEMPERATURE_{*OPTION*}
- *INITIAL_VEHICLE_KINEMATICS

*INITIAL

There are two alternative sets of keywords for setting initial velocities. Cards from one set cannot be combined with cards from the other. **Standard velocity cards:**

*INITIAL_VELOCITY

*INITIAL_VELOCITY_NODE

*INITIAL_VELOCITY_RIGID_BODY

Alternative initial velocity cards supporting initial rotational about arbitrary axes and start times. **Alternative velocity cards:**

*INITIAL_VELOCITY_GENERATION

*INITIAL_VELOCITY_GENERATION_START_TIME

*INITIAL_VOID_{*OPTION*}

*INITIAL_VOLUME_FRACTION

*INITIAL_VOLUME_FRACTION_GEOMETRY

***INITIAL_AIRBAG_PARTICLE_POSITION**

Purpose: This card initializes the position of CPM initial air particle to the location specified.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|---|---|---|---|---|---|---|
| Variable | Bag_ID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

Particle Cards. The i^{th} card specifies the location of the i^{th} particle. LS-DYNA expects one card for each particle, if fewer cards are supplied the coordinates will be reused and particles may share the same location at the beginning of the simulation.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|---|---|---|---|---|---|---|
| Variable | | X | Y | Z | | | | |
| Type | 8x | F | F | F | | | | |
| Default | | | | | | | | |

VARIABLE

DESCRIPTION

| | |
|--------|---|
| Bag_ID | Airbag ID defined in *AIRBAG_PARTICLE_ID card |
| X | x coordinate |
| Y | y coordinate |
| Z | z coordinate |

***INITIAL_ALE_MAPPING**

Purpose: This card initializes the current ALE run with data from the last cycle of a previous ALE run. Data are read from a mapping file specified by “map=” on the command line (see [Remark 6](#)). To map data histories (not just the last cycle) to a region of selected elements, see *BOUNDARY_ALE_MAPPING.

The following transitions are allowed:

| | | |
|---------|---------|---------|
| 1D → 2D | 2D → 2D | 3D → 3D |
| 1D → 3D | 2D → 3D | 3D → 2D |

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|--------|---|---|---|---|---|
| Variable | PID | TYP | AMMSID | | | | | |
| Type | I | I | I | | | | | |
| Default | none | none | none | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-------|-------|---|---|---|
| Variable | X0 | Y0 | Z0 | VECID | ANGLE | | | |
| Type | F | F | F | I | F | | | |
| Default | 0.0 | 0.0 | 0.0 | none | none | | | |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| PID | Part ID or part set ID. |
| TYP | Type of “PID” (see Remark 1): EQ.0: part set ID (PSID). EQ.1: part ID (PID). |
| AMMSID | Set ID of ALE multi-material groups defined in *SET_MULTI-MATERIAL_GROUP. See Remark 1 . |
| X0 | Origin position in global <i>x</i> -direction. See Remarks 2 and 5 . |

| VARIABLE | DESCRIPTION |
|----------|--|
| YO | Origin position in global y -direction. See Remarks 2 and 5 . |
| ZO | Origin position in global z -direction. See Remarks 2 and 5 . |
| VECID | ID of the symmetric axis defined by *DEFINE_VECTOR. See Remarks 3 and 5 . |
| ANGLE | Angle of rotation in degrees around an axis defined by *DEFINE_VECTOR for the 3D to 3D mapping. See Remark 4 . |

Remarks:

- Mapping of Ale Multi-Material Groups.** The routines of this card need to know which mesh will be initialized with the mapping data, and more specifically, which multi-material groups. The first two fields, PID, and TYP, define the mesh. The third field, AMMSID, refers to a multi-material group list ID; see the *SET_MULTI-MATERIAL_GROUP_LIST card. The group list AMMSID should have as many elements as there are groups in the previous calculation (see *ALE_MULTI-MATERIAL_GROUP).

Example: If the previous model has 3 groups, the current one has 5 groups and the following mapping is wanted.

Group 1 from the previous run → Group 3 in the current run
 Group 2 from the previous run → Group 5 in the current run
 Group 3 from the previous run → Group 4 in the current run

The *SET_MULTI-MATERIAL_GROUP_LIST card should be set as follows:

```
*SET_MULTI-MATERIAL_GROUP_LIST
300
3,5,4
```

In special cases, a group can be replaced by another. If Group 4 in the previous example should be replaced by Group 3, the keyword setup would be modified to have -3 instead of 4. The minus sign is a way for the code to know that the replacing group (-3 replaces 4) is a complement of the group 3:

```
*SET_MULTI-MATERIAL_GROUP_LIST
300
3,5,-3
```

- Coordinate System Origin.** The location to which the data is mapped is controlled by the origin of the coordinate system (XO, YO, ZO).

3. **Symmetry Axis.** For a mapping file created by a previous asymmetric model, the symmetric axis orientation in the current model is specified by VECID. For a mapping file created by a 3D or 1D spherical model, the vector VECID is read but ignored. For a 3D to 3D mapping the vector is used if the parameter ANGLE is defined (see [Remark 4](#)).
4. **Rotating 3D Data Onto a 3D calculation.** For a mapping from a previous 3D run to a current 3D model the previous 3D data will be rotated about the vector, VECID, through an angle specified in the ANGLE field.
5. **Plain Strain, and 3D to 2D.** The definitions of X0, Y0, Z0 and VECID change in the case of the following mappings:
 - a) plain strain 2D (ELFORM = 13 in *SECTION_ALE2D) to plain strain 2D
 - b) plain strain 2D to 3D
 - c) 3D to 2D

While, VECID still defines the y -axis in the 2D domain, the 3 first parameters in *DEFINE_VECTOR, additionally, define the location of the origin. The 3 last parameters define a position along the y -axis. For this case when 2D data is used in a 3D calculation the point X0, Y0, Z0 together with the vector, VECID, define the plane.

6. **Mapping File.** Including the command line argument "map=" will invoke the creation of a mapping file. When the keyword INITIAL_ALE_MAPPING is not in the input deck, but the argument "map=" is present on the command line, the ALE data from the last cycle is written in the mapping file. This file contains the following nodal and element data:
 - nodal coordinates (last step)
 - nodal velocities
 - part ids
 - element connectivities
 - element centers
 - densities
 - volume fractions
 - stresses
 - plastic strains
 - internal energies
 - bulk viscosities

- relative volumes

Chained Mappings. To chain mapping operations so that LS-DYNA both reads and writes a mapping file the command line argument “map1=” is necessary. If the keyword INITIAL_ALE_MAPPING is in the input deck and the prompt “map=” is in the command line, the ALE data is read from the mapping file defined by “map=” to initialize the run. Data from the last cycle are written in the mapping file defined by “map1=”.

***INITIAL_AXIAL_FORCE_BEAM**

Purpose: Initialize the axial force resultants in beam elements that are used to model bolts. This option works with *MAT_SPOTWELD with beam type 9, a Hughes-Liu type beam.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-------|-------|---|---|---|---|
| Variable | BSID | LCID | SCALE | KBEND | | | | |
| Type | I | I | F | I | | | | |
| Default | none | none | 1.0 | 0 | | | | |

VARIABLE**DESCRIPTION**

| | |
|-------|---|
| BSID | Beam set ID. |
| LCID | Load curve ID defining preload force versus time. When the load curve ends or goes to zero, the initialization is assumed to be completed. See Remark 2 below. |
| SCALE | Scale factor on load curve. |
| KBEND | Bending stiffness flag EQ.0: Bending stiffness is negligible since all integration points are assigned the same axial stress EQ.1: Bending stiffness is retained by keeping the axial stress gradient |

Remarks:

- Damping.** To achieve convergence during explicit dynamic relaxation, the application of the damping options is very important. If contact is active, contact damping is recommended with a value between 10-20 percent. Additional damping, via the option DAMPING_PART_STIFFNESS also speeds convergence where a coefficient of 0.10 is effective. If damping is not used, convergence may not be possible.
- Ramping.** When defining the load curve, LCID, a ramp starting at the origin should be used to increase the force to the desired value. The time duration of the ramp should produce a quasistatic response. When the end of the load

curve is reached, or when the value of the load decreases from its maximum value, the initialization stops. If the load curve begins at the desired force value, i.e., no ramp, convergence will take much longer, since the impulsive like load created by the initial force can excite nearly every frequency in the structural system where force is initialized.

***INITIAL_CONTACT_WEAR**

Purpose: Initialize contact wear for simulation of wear processes. Define as many cards as desired. See Remarks.

Note that this card is not supposed to be manually inserted; rather it is supposed to be generated by LS-DYNA during wear processes.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|--------|------|------|------|------|------|
| Variable | CID | NID | WDEPTH | NX | NY | NZ | ISEQ | NCYC |
| Type | I | I | F | F | F | F | I | I |
| Default | none | none | none | none | none | none | none | none |

VARIABLE**DESCRIPTION**

| | |
|------------|--|
| CID | Contact Interface ID. |
| NID | Node ID. |
| WDEPTH | Wear depth, in units of length. |
| NX, NY, NZ | Direction vector for wear, internally normalized. |
| ISEQ | Simulation sequence number for the entire process. |
| NCYC | The wear on this card will be processed NCYC times to modify the worn geometry. This means that <i>one</i> LS-DYNA simulation is used to predict the wear for NCYC repetitions of the process to save simulation time. This number should be chosen with care; a negative number means that LS-DYNA will not apply this card. See Remarks below. |

Remarks:

This card is not supposed to be manually inserted, but is automatically generated by LS-DYNA when simulating wear processes; see *CONTACT_ADD_WEAR and parameters NCYC on *INTERFACE_SPRINGBACK_LSDYNA and SPR/MPR on *CONTACT. A sequence of identical simulations, except for perturbation of the geometry of certain components due to wear, is undertaken. For a given contact interface and node ID, the corresponding node is perturbed by the wear depth in the

direction of wear. If the cycle number NCYC is negative, the geometry has been already processed in LS-PrePost and the card is ignored by LS-DYNA. If a node appears multiple times, the wear from the individual sequences is accumulated.

***INITIAL_CRASHFRONT**

Purpose: For some composite materials, the strength of an element is reduced if one of its neighboring elements fails due to damage. The damaged nodes are considered crashfront. In general, all nodes are initially perfect and there are no initial crashfront nodes. However, this card allows the user to initialize crashfront nodes for damage that may occur prior to the simulation, such as during the manufacturing process. Any elements connected to these crashfront nodes are initialized with reduced strength.

The crashfront node set can be initialized using the nodes that are in a set of segments, shell elements, parts, or nodes. This keyword works with material models 17, 54, 55, 58, 169, 261, and 262.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|---|---|---|---|---|---|
| Variable | SID | STYPE | | | | | | |
| Type | I | I | | | | | | |
| Default | none | 0 | | | | | | |

VARIABLE**DESCRIPTION**

SID

Set ID from which the initial crashfront nodes are defined.

STYPE

ID type of SID:

EQ.0: segment set ID,

EQ.1: shell element set ID,

EQ.2: part set ID,

EQ.3: part ID,

EQ.4: node set ID.

***INITIAL_DETONATION**

Purpose: Define points to initiate the location of high explosive detonations in part ID's that use *MAT_HIGH_EXPLOSIVE_BURN (*MAT_008). Also see *CONTROL_EXPLOSIVE_SHADOW. If no *INITIAL_DETONATION is defined, detonation occurs in all the high explosive elements at time = 0.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|----|----|----|----|---|---|---|
| Variable | PID | X | Y | Z | LT | | | |
| Type | I | F | F | F | F | | | |
| Default | all HE | 0. | 0. | 0. | 0. | | | |

Acoustic Boundary Card. Additional card for PID = -1.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|----|----|----|-----|---|---|
| Variable | PEAK | DECAY | XS | YS | ZS | NID | | |
| Type | F | F | F | F | F | I | | |

VARIABLE**DESCRIPTION**

| | |
|-----|--|
| PID | Part ID of the high explosive to be lit, except in the case where the high explosive is modeled using an ALE formulation, in which case PID is the part ID of the mesh where the high explosive material to be lit initially resides. However, two other options are available: EQ.-1: an acoustic boundary, also, *BOUNDARY_USA_SURFACE, EQ.0: all high explosive materials are considered. |
| X | x-coordinate of detonation point, see Figure 24-1 . |
| Y | y-coordinate of detonation point. |
| Z | z-coordinate of detonation point. |

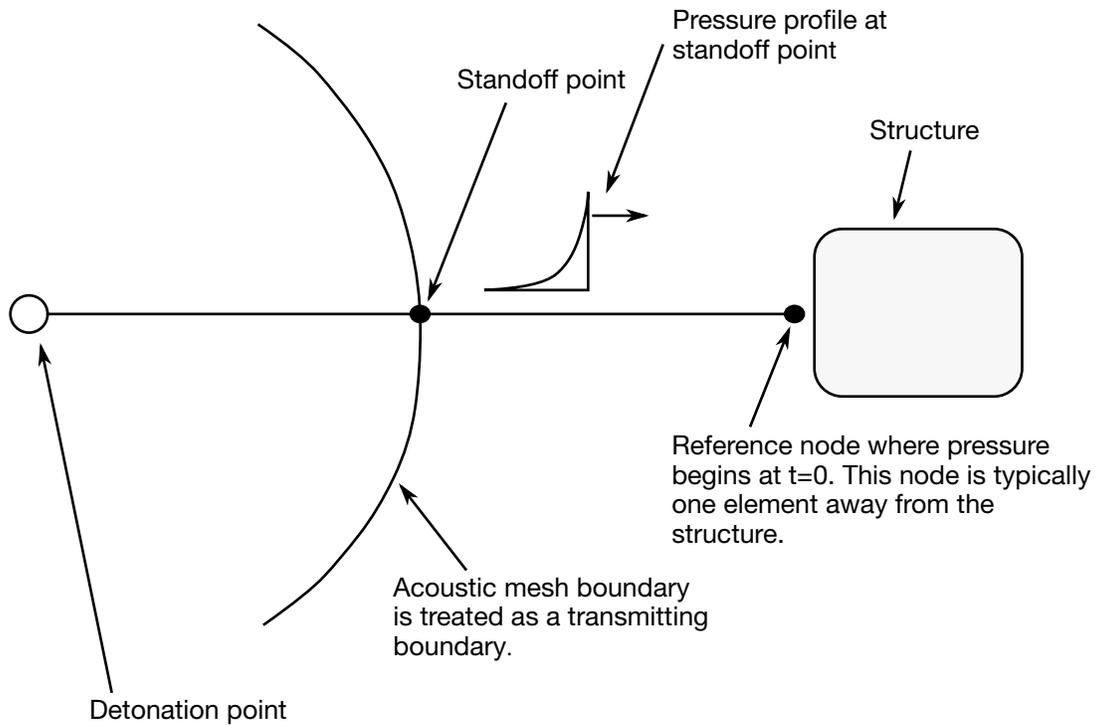

Figure 24-1. Initialization of the initial pressures due to an explosive disturbance is performed in the acoustic media. LS-DYNA automatically determines the acoustic mesh boundary and applies the pressure time history to the boundary. This option is only applicable to the acoustic element formulation, see *SECTION_SOLID.

| VARIABLE | DESCRIPTION |
|----------|--|
| LT | Lighting time for detonation point. This time is ignored for an acoustic boundary. |
| PEAK | Peak pressure, p_o , of incident pressure pulse. See Remark 3. |
| DECAY | Decay constant, τ . See Remark 3. |
| XS | x -coordinate of standoff point; see Figure 24-1. |
| YS | y -coordinate of standoff point |
| ZS | z -coordinate of standoff point |
| NID | Reference node ID near structure |

Remarks:

1. **Lighting Time.** For solid elements (not acoustic) two options are available. If the control card option, *CONTROL_EXPLOSIVE_SHADOW, is not used the

lighting time for an explosive element is computed using the distance from the center of the element to the nearest detonation point, L_d ; the detonation velocity, D ; and the lighting time for the detonator, t_d :

$$t_L = t_d + \frac{L_d}{D}.$$

The detonation velocity for this default option is taken from the element whose lighting time is computed and does not account for the possibilities that the detonation wave may travel through other explosives with different detonation velocities or that the line of sight may pass outside of the explosive material.

If the control card option, ***CONTROL_EXPLOSIVE_SHADOW**, is defined, the lighting time is based on the shortest distance through the explosive material. If inert obstacles exist within the explosive material, the lighting time will account for the extra time required for the detonation wave to travel around the obstacles. The lighting times also automatically accounts for variations in the detonation velocity if different explosives are used. No additional input is required for this option, but care must be taken when setting up the input. This option works for two and three-dimensional solid elements. It is recommended that for best results:

- a) Keep the explosive mesh as uniform as possible with elements of roughly the same dimensions.
 - b) Inert obstacle such as wave shapers within the explosive must be somewhat larger than the characteristic element dimension for the automatic tracking to function properly. Generally, a factor of two should suffice. The characteristic element dimension is found by checking all explosive elements for the largest diagonal.
 - c) The detonation points should be either within or on the boundary of the explosive. Offset points may fail to initiate the explosive. When LT is nonzero, the detonation point is fixed to the explosive material at $t = 0$ and moves as the explosive material moves prior to detonation.
 - d) Check the computed lighting times in the post processor LS-PrePost. The lighting times may be displayed at time = 0., state 1, by plotting component 7 (a component normally reserved for plastic strain) for the explosive material. The lighting times are stored as negative numbers. The negative lighting time is replaced by the burn fraction when the element ignites.
2. **Line Detonations.** Line detonations may be approximated by using a sufficient number of detonation points to define the line. Too many detonation points may result in significant initialization cost.

3. **Acoustic Boundary.** The pressure as a function of time curve for the acoustic boundary is defined by:

$$p(t) = p_o e^{-\frac{t}{\tau}}.$$

*INITIAL_EOS_ALE

Purpose: This card initializes the pressure in ALE elements that have materials with *EOS.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|-----|-----|-----|---|---|
| Variable | ID | TYP | MMG | E0 | V0 | P0 | | |
| Type | I | I | I | F | F | F | | |
| Default | none | none | none | 0.0 | 0.0 | 0.0 | | |

VARIABLE**DESCRIPTION**

| | |
|-----|--|
| ID | Part ID or part set ID or element set ID. |
| TYP | Type of "ID": EQ.0: part set ID. EQ.1: part ID. EQ.2: element set ID (*SET_BEAM in 1D, *SET_SHELL in 2D, *SET_SOLID in 3D). |
| MMG | Specifies the multi-material group. GT.0: ALE multi-material group. LT.0: Set ID of ALE multi-material groups defined in *SET_-MULTI-MATERIAL_GROUP. |
| E0 | Initial internal energy per reference volume unit (as defined in *EOS). See Remark 1 . |
| V0 | Initial relative volume (as defined in *EOS). See Remark 1 . |
| P0 | Initial pressure. See Remark 2 . |

Remarks:

- Initialization with Volume and Energy.** For most *EOS, E0 and V0 should be used to initialize the pressure. If only the internal energy is initialized, V0 should be 1.0 (If V0 = 0.0, E0 will not be applied).

2. **Initial Pressure with Derived Volume and Energy.** For *EOS_001, *EOS_004 and *EOS_006, the initial pressure P0 can be input directly. An iterative method will compute the initial internal energy and relative volume. This approach is applied if E0 = 0.0 and V0 = 0.0.

***INITIAL_FATIGUE_DAMAGE_RATIO_{OPTION}**

Available options include:

<BLANK>

BINARY

Purpose: This card sets the initial damage ratio for fatigue analysis. The initial damage ratio may come from the previous loading cases. The initial damage ratio can be defined by user directly, or can be extracted from an existing binary database like D3FTG (using the option BINARY).

Card 1 for no option, <BLANK>.

| | | | | | | | | |
|----------|---------|------|--------|---|---|---|---|---|
| Card 1a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | PID/SID | PTYP | DRATIO | | | | | |
| Type | I | I | F | | | | | |
| Default | none | 0 | 0.0 | | | | | |

Card 1 for option BINARY.

| | | | | | | | | |
|----------|----------|---|---|---|---|---|---|---|
| Card 1b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | FILENAME | | | | | | | |
| Type | C | | | | | | | |
| Default | d3ftg | | | | | | | |

VARIABLE

DESCRIPTION

| | |
|---------|---|
| PID/SID | Part ID or part set ID for which the initial damage ratio is defined. |
| PTYP | Type of PID/SID: EQ.0: part ID. EQ.1: part set ID. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| DRATIO | Initial damage ratio. |
| FILENAME | Path and name of existing binary database for fatigue information. |

Remarks:

1. **Fatigue Problem Types.** This card works for both time domain fatigue and frequency domain fatigue problems.
2. **Multiple Loading Cases.** Card 1 can be repeated if the model has an initial damage ratio coming from multiple loading cases.

*INITIAL_FIELD_SOLID

Purpose: This keyword is a simplified version of *INITIAL_STRESS_SOLID which can be used with hyperelastic materials. The keyword is used for history variable input. Data is usually in the form of the eigenvalues of diffusion tensor data. These are expressed in the global coordinate system.

NOTE: As of LS-DYNA R5 in all contexts, other than *MAT_TISSUE_DISPERSSED, this keyword is deprecated (and disabled). For all other materials this keyword has been superceded by *INITIAL_STRESS_SOLID.

Card Sets: Include as many pairs of Cards 1 and 2 as necessary. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-------|---|---|---|---|---|
| Variable | EID | NINT | NHISV | | | | | |
| Type | I | I | I | | | | | |
| Default | none | none | 0 | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | FLD1 | FLD2 | FLD3 | FLD4 | FLD5 | FLD6 | FLD7 | FLD8 |
| Type | F | F | F | F | F | F | F | F |

| VARIABLE | DESCRIPTION |
|----------|--|
| EID | Element ID |
| NINT | Number of integration points (should correspond to the solid element formulation). |
| NHISV | Number of field variables. If NHISV exceeds the number of integration point field variables required by the constitutive model, only the number required is output; therefore, if in doubt, set NHISV to a large number. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| FLD n | Data for the n^{th} field (history) variable. NOTE that *MAT_TISSUE_DISPERSED only use FLD1 to FLD3 since NHISV = 3. |

Remarks:

Add as many cards as necessary. The keyword input ends at the next keyword ("**") card. For example for two elements it can look as:

```
*INITIAL_FIELD_SOLID
$EID      NINT      NHISV
   1         1         3
$FLD1     FLD2      FLD3
   0.1      0.8      0.1
$EID      NINT      NHISV
   2         1         3
$FLD1     FLD2      FLD3
   0.3      0.2      0.5
```

*INITIAL_FOAM_REFERENCE_GEOMETRY_{OPTION}

Available options include:

<BLANK>

RAMP

Purpose: The reference configuration allows stresses to be initialized (via REF in *MAT) for the following hyperelastic material models: 2, 5, 7, 21, 23, 27, 31, 38, 57, 73, 77, 83, 132, 179, 181, 183, and 189. Supported solid elements are the constant stress hexahedron (#1), the fully integrated S/R hexahedron (#2), the tetrahedron (#10), and the pentahedron (#15).

To use this option, the geometry of the foam material is defined in a deformed configuration. The stresses in the low density foam then depend only on the deformation gradient matrix F_{ij} :

$$F_{ij} = \frac{\partial x_i}{\partial X_j}$$

where x_i is the deformed configuration and X_j is the undeformed configuration. By using this option, dynamic relaxation can be avoided once a deformed configuration is obtained usually on the first run of a particular problem.

Card Summary:

Card 1. This card is included if and only if the RAMP option is used.

| | | | | | | | |
|--------|--|--|--|--|--|--|--|
| NDTRRG | | | | | | | |
|--------|--|--|--|--|--|--|--|

Card 2. Include as many of this card as necessary. This input ends at the next keyword ("*") card.

| | | | | | | |
|-----|---|---|---|--|--|--|
| NID | X | Y | Z | | | |
|-----|---|---|---|--|--|--|

Data Cards:**RAMP Card.** Additional card for the option of RAMP.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|---|---|---|---|---|---|---|
| Variable | NDTRRG | | | | | | | |
| Type | I | | | | | | | |

| Default | none | 0. | 0. | 0. | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| NDTRRG | Number of time steps taken for an element to restore its reference geometry. Definition of NDTRRG allows an element to ramp up to its reference shape in NDTRRG time steps. Currently LS-Dyna uses only one value of NDTRRG and applies it to all foam materials with reference geometries. If more than one NDTRRG is defined, the one defined last will be used. |
| NID | Node number |
| X | <i>x</i> -coordinate in reference configuration |
| Y | <i>y</i> -coordinate in reference configuration |
| Z | <i>z</i> -coordinate in reference configuration |

***INITIAL_GAS_MIXTURE**

Purpose: This command is used to specify (a) which ALE multi-material groups may be present inside an ALE mesh set at time zero, and (b) the corresponding reference gas temperature and density which define the initial thermodynamic state of the gases. The order of the species in the gas mixture corresponds to the order of different gas species defined in the associated *MAT_GAS_MIXTURE card. This card must be used together with a *MAT_GAS_MIXTURE card or, equivalently, a *MAT_ALE_GAS_MIXTURE card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|-------|------|---|---|---|---|
| Variable | SID | STYPE | MMGID | TEMP | | | | |
| Type | I | I | I | F | | | | |
| Default | none | 0 | none | none | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-----|-----|-----|-----|

| Default | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 |

VARIABLE**DESCRIPTION**

SID

Set ID for initialization. This SID defines the ALE mesh within which certain ALE multi-material group(s) may be present at $t = 0$.

STYPE

Set type for the SID above:

EQ.0: SID is a part set ID

EQ.1: SID is a part ID

MMGID

ALE Multi-material group ID of the material that may be present at $t = 0$ in the ALE mesh set defined by SID.

| VARIABLE | DESCRIPTION |
|----------|---|
| TEMP | Initial static temperature of the gas species occupying the ALE mesh. Note that all species in the mixture are assumed to be in thermal equilibrium (having the same T). |
| RO1-RO8 | Initial densities of the ALE material(s) which may be occupying some region (or all) of the aforementioned ALE mesh, for up to eight different gas species. The order of the density input corresponds to the order of the materials defined in associated *MAT_GAS_MIXTURE card. |

Remarks:

- Example.** Please see the example under the *MAT_GAS_MIXTURE card definition for an application of the *INITIAL_GAS_MIXTURE card.
- Initial Pressure.** The temperature is assumed to be the initial temperature which together with the gas density, will define the initial pressure of the gas species using the perfect gas law,

$$P|_{t=0} = \rho|_{t=0}(C_P - C_V)T|_{t=0} .$$

The user should manually check the initial pressure for consistency.

- ALE Multi-Material Groups.** Given an ALE mesh, this mesh may initially be occupied by one or more ALE multi-material groups (AMMG). For example, a background ALE mesh (H1) containing AMMG 1 may be partially filled with AMMG 2 using the volume filling command *INITIAL_VOLUME_FRACTION_GEOMETRY. Then there are 2 AMMGs to be initialized for this mesh H1. The commands look like the following.

```

$-----
$ One card is defined for each AMMG that will occupy some elements of a mesh
set
*INITIAL_GAS_MIXTURE

```

*INITIAL_HYDROSTATIC_ALE

Purpose: When an ALE model contains one or more regular (not reservoir-type) ALE parts (ELFORM = 11 and AET = 0), this command may be used to initialize the hydrostatic pressure field in the regular ALE domain due to gravity. The *LOAD_BODY_(OPTION) keyword must be defined.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|-------|-------|------|-------|---|---|---|
| Variable | ALESID | STYPE | VECID | GRAV | PBASE | | | |
| Type | I | I | I | F | F | | | |
| Default | none | 0 | none | 0.0 | 0.0 | | | |

Multi-material Layers Group Cards. Repeat card 2 as many times as the number of AMMG layers present in the model.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|---|---|---|---|---|---|
| Variable | NID | MMGBLO | | | | | | |
| Type | I | I | | | | | | |
| Default | none | none | | | | | | |

VARIABLE

DESCRIPTION

- ALESID ALESID is a set ID defining the ALE domain/mesh whose hydrostatic pressure field due to gravity is being initialized by this keyword. See [Remark 2](#) and [4](#).
- STYPE ALESID set type. See [Remark 4](#).
EQ.0: Part set ID (PSID),
EQ.1: Part ID (PID),
EQ.2: Solid set ID (SSID).
- VECID Vector ID of a vector defining the direction of gravity.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| GRAV | Magnitude of the Gravitational acceleration. For example, in metric units the value is usually set to 9.80665 m/s ² . |
| PBASE | Nominal or reference pressure at the top surface of all fluid layers. By convention, the gravity direction points from the top layer to the bottom layer. Each fluid layer must be represented by an ALE multi-material group ID (AMMGID or MMG). See Remark 1 . |
| NID | Node ID defining the top of an ALE fluid (AMMG) layer. |
| MMGBLO | AMMG ID of the fluid layer immediately below this NID. Each node is defined in association with one AMMG layer below it. See Remark 3 . |

Remarks:

1. **Pressure in Multi-Layer Fluids.** For models using multi-layer ALE Fluids the pressure at the top surface of the top fluid layer is set to PBASE and the hydrostatic pressure is computed as following

$$P = P_{\text{base}} + \sum_{i=1}^{N_{\text{layers}}} \rho_i g h_i .$$

2. **Limitations on Element Formulation.** This keyword applies only to the regular ALE parts with ELFORM = 11 and AET = 0 on the *SECTION_SOLID and *SECTION_ALE2D cards (not reservoir-type). This keyword cannot be used to initialize reservoir-type ALE parts (AET = 4). Also, ramping functions are not supported, so the loading is done in one step at $t = 0$. For initializing reservoir-type ALE domain, please review the *ALE_AMBIENT_HYDROSTATIC keyword.
3. **Limitation on EOS Model.** The keyword only supports *EOS_GRUNEISEN and *EOS_LINEAR_POLYNOMIAL, but only in the following two cases:

$$\begin{aligned} c_3 = c_4 = c_5 = c_6 = 0, & \quad E_0 = 0 \\ c_4 = c_5 > 0, & \quad c_1 = c_2 = c_3 = c_6 = 0, \quad V_0 = 0. \end{aligned}$$

4. **Structured ALE usage.** When used with structured ALE, the PART and PART set options might not make too much sense. This is because all elements inside a structured ALE mesh are assigned to one single PART ID. If we want to prescribe initial hydrostatic pressure for all the elements inside the structured mesh, we can certainly use that PART ID. But if we only want to do that to some elements, we must generate a solid set which contains those structured

ALE elements. This is done by using the *SET_SOLID_GENERAL keyword with SALECPT option and STYPE = 2 (solid element set ID) on this keyword.

Example:

Model Summary: Consider a model consisting of 2 ALE parts, air on top of water.

H1 = AMMG1 = Air part above.

H2 = AMMG2 = Water part below.

```

```

***INITIAL_IMPULSE_MINE**

Purpose: Apply initial velocities to the nodes of a three-dimensional structure due to the impulse imparted by the detonation of a buried land mine. This keyword cannot be used with 2D models or with rigid parts. It is also not supported by MPP (see workaround in [Remark 3](#)). This feature is based on the empirical model developed by [Tremblay 1998].

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------------------|-------------------|------|-------|------|-------|----------|------|
| Variable | SSID | MTNT | RHOS | DEPTH | AREA | SCALE | not used | UNIT |
| Type | I | F | F | F | F | F | | I |
| Default | none | 0.0 | 0.0 | 0.0 | 0.0 | 1.0 | | 1 |
| Remarks | 1 | 4 | | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-------|------|--------|------|--------|
| Variable | X | Y | Z | NIDMC | GVID | TBIRTH | PSID | SEARCH |
| Type | F | F | F | I | I | F | I | F |
| Default | 0.0 | 0.0 | 0.0 | 0 | none | 0.0 | 0 | 0.0 |

VARIABLE**DESCRIPTION**

| | |
|-------|--|
| SSID | Segment set ID. See *SET_SEGMENT and Remark 1 . |
| MTNT | Equivalent mass of TNT. See Remark 4 . |
| RHOS | Density of overburden soil. |
| DEPTH | Burial depth from the ground surface to the center of the mine. This value must be positive. |
| AREA | Cross sectional area of the mine. |
| SCALE | Scale factor for the impulse. |

| VARIABLE | DESCRIPTION |
|----------|---|
| UNIT | Unit system. This must match the units used by finite element model. EQ.1: inch, dozen slugs (i.e., lbf × s ² /in), second, PSI (default) EQ.2: meter, kilogram, second, Pascal EQ.3: centimeter, gram, microsecond, megabar EQ.4: millimeter, kilogram, millisecond, GPa EQ.5: millimeter, metric ton, second, MPa EQ.6: millimeter, gram, millisecond, MPa |
| X, Y, Z | x-, y-, and z- coordinates of mine center. |
| NIDMC | Optional node ID representing the mine center (see *NODE). If defined then X, Y and Z are ignored. |
| GVID | Vector ID representing the vertically upward direction, that is, the normal to the ground surface. See *DEFINE_VECTOR. |
| TBIRTH | Birth time. Impulse is activated at this time. |
| PSID | Part set ID identifying the parts affected by the mine. See *SET_PART. If PSID is set to zero, the part affected by the mine defaults to the part comprised by the nodes of the segment set. |
| SEARCH | Limit the search depth into the structure. Initial nodal velocity is distributed from the segment to a depth equal to the SEARCH value. The value must be positive. If set to zero, the search depth is unlimited and extends through the part(s) identified by PSID. |

Remarks:

1. **Orientation.** Segment normals should nominally point toward the mine.
2. **Element Types.** The segments should belong to 3D thin shell, solid, or thick shell elements. This keyword cannot be used with 2D geometries.
3. **Workaround to Use MPP.** Although this feature is unavailable in MPP, there is a simple workaround which involves performing the initialization in SMP, then using that initial velocity field in MPP.
4. **Equivalent Mass of TNT.** Several methods can be used to approximate the equivalent mass of TNT for a given explosive. One method involves scaling

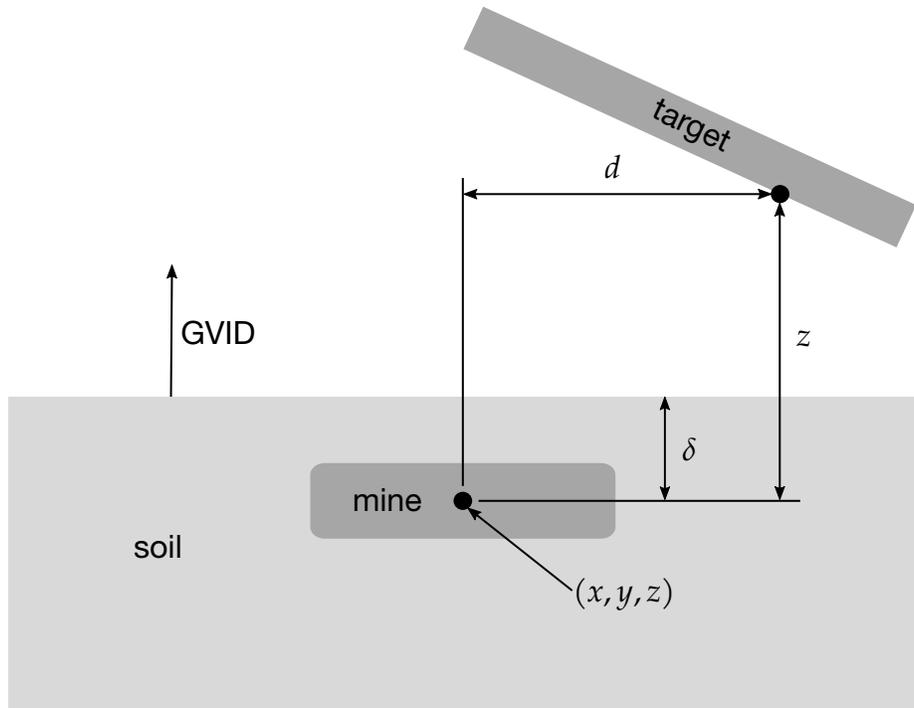

Figure 24-2. Schematic of the buried mine parameters.

the mass by the ratio of the squares of the Chapman-Jouguet detonation velocities given by:

$$M_{TNT} = M_e \frac{v_e^2}{v_{TNT}^2}$$

where M_{TNT} is the equivalent TNT mass and v_{TNT} is the Chapman-Jouguet detonation velocity of TNT. M_e and v_e are, respectively, the mass and C-J velocity of the explosive under investigation. LS-DYNA takes the density of "Standard" TNT to be $1.57 \frac{g}{cm^3}$ and v_{TNT} to be $0.693 \frac{cm}{\mu s}$

5. **Energy Release.** This implementation assumes the energy release (heat of detonation) for 1 kilogram of TNT is 4.516 MJ.
6. **Error Bounds.** Prediction of the impulse relies on an empirical approach which involves fitting curves to experimental results. The upper error bound is 1.8 times the predicted value and the lower is the predicted value divided by 1.8. Thus, if the predicted impulse is 10 kN-seconds, then the solution space ranges from 5.6 kN-sec to 18 kN-sec.
7. **Limits of Model's Validity.** The computed impulse is valid when the following criteria are met:

$$0.106 \leq \frac{\delta}{z} \leq 1$$

$$6.35 \leq \frac{E/A}{\rho c^2 z} \leq 150$$
$$0.154 \leq \frac{\sqrt{A}}{z} \leq 4.48$$
$$0 \leq \frac{d}{z} \leq 19.3$$

where,

δ = the distance from the mine center to the ground surface (DEPTH)

z = the vertical distance from the mine center to the target point

E = the energy release of the explosive

A = the cross-sectional area of the mine (AREA)

ρ = the soil density (RHOS)

c = the wave speed in the soil

d = the lateral distance from the mine center to the target point.

See [Figure 24-2](#).

***INITIAL_INTERNAL_DOF_SOLID_OPTION**

Available Options include:

TYPE3

TYPE4

Purpose: Initialize the internal degrees of freedom for solid element types 3 and 4.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | LID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

Value Cards. Include 12 cards for type 3 and 6 cards for type 4.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|---|---|---|---|---|
| Variable | VALX | VALY | VALZ | | | | | |
| Type | F | F | F | | | | | |
| Default | none | none | none | | | | | |

VARIABLE**DESCRIPTION**

| | |
|------|--|
| LID | Element ID. |
| VALX | x component of internal degree of freedom. |
| VALY | y component of internal degree of freedom. |
| VALZ | z component of internal degree of freedom. |

Remarks:

1. **Internal DOF.** The internal degrees of freedom are specified in terms of the displacements of the corresponding mid-side nodes of the 20 node hex and the

10 node tetrahedron that are the basis of the type 3 and 4 solid elements, respectively.

***INITIAL_LAG_MAPPING_{OPTION}**

The available options are

<BLANK>

WRITE

Purpose: This card initializes a 3D Lagrangian calculation with data from the last cycle of a preceding 2D or 3D Lagrangian calculation.

In its *INITIAL_LAG_MAPPING form (<BLANK> option), this keyword causes data to be read in from a *mapping file*; while, with the WRITE active this card is used to set which parts are written to the mapping file. The mapping file's filename is specified using the "lagmap=" command line argument (see [Remarks 1](#) and [2](#)).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|---|---|---|---|---|---|
| Variable | SETID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

Card 2. Additional card for <BLANK> keyword option.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-------|-------|---------|---|---|
| Variable | XP | YP | ZP | VECID | ANGLE | NELANGL | | |
| Type | F | F | F | I | F | I | | |
| Default | 0.0 | 0.0 | 0.0 | none | none | 0 | | |

VARIABLE**DESCRIPTION**

SETID

part set ID. See [Remarks 3](#) and [4](#).

XP

x-position of a point belonging to the plane from which the 3D mesh is generated (only for a 2D to 3D mapping). See [Remark 5](#).

| VARIABLE | DESCRIPTION |
|-----------------|--|
| YP | <i>y</i> -position of a point belonging to the plane from which the 3D mesh is generated (only for a 2D to 3D mapping). See Remark 5 . |
| ZP | <i>z</i> -position of a point belonging to the plane from which the 3D mesh is generated (only for a 2D to 3D mapping). See Remark 5 . |
| VECID | ID of the rotation axis (symmetric axis for a 2D to 3D mapping) defined by *DEFINE_VECTOR. See Remark 5 . |
| ANGLE | Angle of rotation around an axis defined by *DEFINE_VECTOR. See Remark 5 . |
| NELANGL | Number of elements to create in the azimuthal direction for ANGLE (only for a 2D to 3D mapping). See Remark 5 . EQ.-1:No mesh is generated or projected. See Remark 5 . |

Remarks:

1. **The Mapping File as Output.** In the absence of a *INITIAL_LAG_MAPPING card, adding a "lagmap=" argument to the command line will cause LS-DYNA to write a mapping file. This file contains the following nodal and element data:
 - nodal coordinates (initial and last steps)
 - nodal velocities
 - nodal temperatures (if *CONTROL_THERMAL_SOLVER is used)
 - part ids
 - element connectivities
 - element centers
 - densities
 - volume fractions
 - stresses
 - plastic strains
 - internal energies
 - bulk viscosities
 - relative volumes

2. **The Mapping File as Input.** If the keyword INITIAL_LAG_MAPPING is in the input deck and the "lagmap=" argument is in the command line, then Lagrangian data is read from the mapping file defined by "lagmap=" to initialize the run.
3. **Part Sets (Write).** The part set, SETID, defines which parts are involved in the mapping. The WRITE option can be used to write data in the mapping file for ONLY the parts specified by the set. If the keyword INITIAL_LAG_MAPPING_WRITE is not included in the input deck then ALL Lagrangian parts are written in the mapping file during the last cycle. Similarly, for reading
4. **Part Sets (Read).** The mapping initializes the data for every node and element defined by SETID within the domain swept by the 2D mesh or the region initially occupied by the previous 3D mesh. For nodes and elements outside of SETID it has no effect.
5. **Embedding.** The first point in the definition of the rotation axis VECID specifies the origin location for the previous run in the current 3D space. The 2D to 3D mapping depends on whether or not a 3D mesh has already been defined. The 3D to 3D mapping needs a pre-existing mesh.
 - a) *No Mesh Case for a 2D to 3D mapping.* If there is no 3D mesh (no solid and shell with parts in SETID), the point (XP, YP, ZP) together with the symmetry axis (VECID) are used to generate a mesh. The point defines the plane in which the 2D is embedded. The 3D mesh is generated by rotating the 2D mesh around the axis. The point (XP, YP, ZP) must not be on the symmetry axis. ANGLE defines the angle of rotation in degrees. The rotation is counterclockwise when viewed from the axis head. NELANGL is the number of elements to generate in the azimuthal direction.
 - b) *Pre-existing Mesh Case for a 2D to 3D mapping.* If there is a 3D mesh (solids or shells with parts in SETID), the nodes should be within the domain swept by the initial positions of the 2D mesh. Then, the nodes are projected to new locations based on the last mesh positions of the previous run. If NELANGL = -1, the nodes should be within the domain swept by the final positions of the 2D mesh and the mesh location is not modified.
 - c) *Pre-existing Mesh Case for a 3D to 3D mapping.* If there is a 3D mesh (solids or shells with parts in SETID), the nodes should be in the region initially occupied by the previous 3D mesh. Then, the nodes are mapped to new locations based on the last mesh positions of the previous run. VECID is an axis of rotation of the pre-existing mesh if ANGLE is defined. If this latter is not defined, the first point in VECID is still the previous origin location and it can be used to translate the pre-existing mesh. If

NELANGL = -1, the nodes should be in the region finally occupied by the previous 3D mesh and the mesh location is not modified.

*INITIAL

*INITIAL_MOMENTUM

*INITIAL_MOMENTUM

Purpose: Define initial momentum to be deposited in solid elements. This keyword crudely simulates an impulsive type of loading.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|----|----|----|------|---|---|---|
| Variable | EID | MX | MY | MZ | DEPT | | | |
| Type | I | F | F | F | F | | | |
| Default | none | 0. | 0. | 0. | 0. | | | |

VARIABLE

DESCRIPTION

| | |
|------|-----------------------|
| EID | Element ID |
| MX | Initial x -momentum |
| MY | Initial y -momentum |
| MZ | Initial z -momentum |
| DEPT | Deposition time |

Remarks:

Assuming an 8-noded brick element, the specified momentum is distributed equally to each node of the element, and the change in velocity due to this deposited momentum is added to the nodal velocity at the specified deposition time.

***INITIAL_PWP_DEPTH_{OPTION}**

The available options include:

<BLANK>

SET

Purpose: Initialize pore water pressure in solid elements where a non-hydrostatic profile is required.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|------|---|---|---|---|---|---|
| Variable | PID/PSID | LC | | | | | | |
| Type | I | I | | | | | | |
| Default | none | none | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| PID | Part ID or Part Set ID for the SET keyword option |
| LC | Curve of pore water pressure head (length units) as a function of z-coordinate |

Remarks:

This feature overrides the automatically calculated hydrostatic pressure profile; the hydrostatic pressure profile is the default behavior for a part with pore fluid. The points in the curve must be ordered with the most negative z-coordinate first – this order looks “upside-down” on the page.

***INITIAL_PWP_NODAL_DATA**

Purpose: Initialize nodal pore pressure data. This keyword is written by LS-DYNA to the dynain file if *CONTROL_PORE_FLUID is present, to enable subsequent analyses beginning from a state reached in a previous analysis. It is not expected that users will create or modify this keyword.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|-----|---|---|---|---|---|
| Variable | NID | NHISV | PID | | | | | |
| Type | I | I | I | | | | | |
| Default | none | 0 | 0 | | | | | |

History Variable Cards. Define as many cards as necessary to define the NHISV variables. For example, if NHISV = 25, then 5 cards are required.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|-------|---|-------|---|-------|---|-------|---|-------|----|
| Variable | HISV1 | | HISV2 | | HISV3 | | HISV4 | | HISV5 | |
| Type | F | | F | | F | | F | | F | |

VARIABLE**DESCRIPTION**

| | |
|--------------------------|--|
| NID | Node ID |
| NHISV | Number of nodal pore pressure history variables. |
| PID | Part ID with which this node is associated for purposes of evaluating pore fluid related properties. |
| HISV _{<i>i</i>} | Define NHISV history variables. |

*INITIAL_STRAIN_SHELL_{OPTION}

The available options include:

<BLANK>

SET

Purpose: Initialize strain tensor for shell element. This option is primarily for multi-stage metal forming operations where the accumulated strain is of interest.

These strain tensors are defined at the inner and outer integration points and are used for post-processing only. There is no interpolation with this option and the strains are defined in the global Cartesian coordinate system. The *DATABASE_EXTENT_BINARY flag STRFLG must be set to unity for this option to work. When OPTION is blank, users have the option to define strains at all integration points by providing nonzero NPLANE, NTHICK and setting INTOUT flag of *DATABASE_EXTENT_BINARY to either "STRAIN" or "ALL".

Card Sets. Define as many shell elements in this section as desired, one set of cards per element. The input is assumed to terminate when a new keyword is detected.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|--------|-------|---|---|---|--------|
| Variable | EID | NPLANE | NTHICK | LARGE | | | | ILOCAL |
| Type | I | I | I | I | | | | I |
| Default | none | none | none | 0 | | | | 0 |

Ordering of Integration Points

When NPLANE and NTHICK are defined, include NPLANE x NTHICK cards below. For each through thickness point define NPLANE points. NPLANE should be either 1 or 4 corresponding to either 1 or 4 Gauss integration points. If four integration points are specified, they should be ordered such that their in plane parametric coordinates are at:

$$\left(-\frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}\right), \quad \left(\frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}\right), \quad \left(\frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3}\right), \quad \left(-\frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3}\right)$$

respectively.

Strain Cards for LARGE = 0.

When NPLANE and NTHICK are not defined or when the SET option is used, define two cards below, one for the inner integration point and the other for the outer integration point, respectively. Otherwise define NPLANE x NTHICK cards, one card for each integration point.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|-------|-------|-------|----|---|
| Variable | EPSxx | EPSyy | EPSzz | EPSxy | EPSyz | EPSzx | T | |
| Type | F | F | F | F | F | F | F | |
| Default | none | none | none | 0. | | | 0. | |

Strain Cards for LARGE = 1.

When NPLANE and NTHICK are not defined or when the SET option is used, define two pairs of cards below, one pair for the inner integration point and the other pair for the outer integration point, respectively. Otherwise define NPLANE x NTHICK pairs of cards; one pair for each integration point.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|-------|---|-------|---|-------|---|-------|---|-------|----|
| Variable | EPSxx | | EPSyy | | EPSzz | | EPSxy | | EPSyz | |
| Type | F | | F | | F | | F | | F | |

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|-------|---|---|---|---|---|---|---|---|----|
| Variable | EPSzx | | T | | | | | | | |
| Type | F | | F | | | | | | | |

VARIABLE**DESCRIPTION**

EID

Element ID or shell element set ID when the SET option is used.

| VARIABLE | DESCRIPTION |
|-------------------|--|
| NPLANE | Number of in-plane integration points being output (not read when the SET option is used). |
| NTHICK | Number of integration points through the thickness (not read when the SET option is used). |
| LARGE | Large format flag: EQ.0: off, EQ.1: on. Each strain field is twice as long for higher precision. |
| ILOCAL | Flag for coordinate system of strain components: EQ.0: global, EQ.1: local (not supported). |
| EPS _{ij} | Define the <i>ij</i> strain component. The strains are defined in the GLOBAL Cartesian system. |
| T | Parametric coordinate of through thickness integration point between -1 and 1 inclusive. |

***INITIAL_STRAIN_SHELL_NURBS_PATCH**

Purpose: Initialize strain tensor and thicknesses at in-plane integration points for isogeometric shell elements. This option is primarily for multi-stage metal forming operations where the accumulated strain and the thickness change is of interest.

The strain tensors are defined at the inner and outer integration points and are used for post-processing only. There is no interpolation with this option and the strains are defined in the global Cartesian coordinate system.

Card Sets. Define as many NURBS shell elements in this section as desired, *one set of cards per element*. The input is assumed to terminate when a new keyword is detected.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

| Variable | EPSZZ | | EPSXY | | EPSYZ | | EPSZX | | THKI | |
| Type | F | | F | | F | | F | | F | |

| <u>VARIABLE</u> | <u>DESCRIPTION</u> |
|-----------------|--|
| EID | NURBS Element ID |
| NPLANE | Number of in-plane integration points being output |
| ITHK | Flag for initialization of thicknesses at in-plane IPs EQ.0: off EQ.1: on. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| LARGE | Large format flag: EQ.0: off, EQ.1: on. Each strain field is twice as long for higher precision. |
| R | Parametric r -coordinate of location of in-plane integration point (with respect to NURBS patch definition) |
| S | Parametric s -coordinate of location of in-plane integration point (with respect to NURBS patch definition) |
| T | Parametric coordinate of through thickness integration point between -1 and 1 inclusive. |
| EPS $_{ij}$ | Define the ij strain component. The strains are defined in the GLOBAL Cartesian system. |
| THKI | Thickness value at in-plane integration point |

***INITIAL_STRAIN_SOLID_{OPTION}**

The available options include:

<BLANK>

SET

Purpose: Initialize strain tensor at element center. This keyword can be used for multi-stage metal forming operations where the accumulated strain is of interest.

These strain tensors are defined at the element center and are used for post-processing only. The strains are defined in the global Cartesian coordinate system. The *DATABASE_EXTENT_BINARY flag STRFLG must be set to unity for this keyword to work. This capability is not available for the cohesive element since it is based on displacements, not strains.

Card Sets. Define as many solid elements in this section as desired: *one pair of cards per element*. The input is assumed to terminate when a new keyword ("*") card is detected.

Element ID Cards.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | EID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

Strain Cards.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|-------|-------|-------|---|---|
| Variable | EPSxx | EPSyy | EPSzz | EPSxy | EPSyz | EPSzx | | |
| Type | F | F | F | F | F | F | | |

VARIABLE**DESCRIPTION**

EID

Element ID or solid element set ID when the SET keyword option is used.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| EPS_{ij} | Define the ij^{th} strain component. The strains are defined in the global cartesian system. |

*INITIAL_STRAIN_SOLID_NURBS_PATCH

Purpose: Initialize strain at integration points for isogeometric solid elements.

These strain tensors are used for post-processing only. There is no interpolation with this option and the strains are defined in the global Cartesian coordinate system.

Card Sets. Define as many NURBs solid elements in this section as desired, *one set of cards per element*. The input is assumed to terminate when a new keyword ("**") card is detected.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-------|---|---|---|---|---|
| Variable | EID | NIP | LARGE | | | | | |
| Type | I | I | I | | | | | |
| Default | none | none | 0 | | | | | |

Strain Cards for LARGE = 0.

For each NIP integration points, define a pair of cards below.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|---|---|---|---|---|
| Variable | R | S | T | | | | | |

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|-------|---|-------|---|-------|---|-------|---|---|----|
| Variable | EPSZZ | | EPSXY | | EPSYZ | | EPSZX | | | |
| Type | F | | F | | F | | F | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| EID | NURBS element ID |
| NIP | Number of integration points being output |
| LARGE | Large format flag: EQ.0: off, EQ.1: on. Each strain field is twice as long for higher precision. |
| R | Parametric r -coordinate of location of in-plane integration point (with respect to NURBS patch definition) |
| S | Parametric s -coordinate of location of in-plane integration point (with respect to NURBS patch definition) |
| T | Parametric t -coordinate of location of in-plane integration point (with respect to NURBS patch definition) |
| EPS $_{ij}$ | Define the ij strain component. The strains are defined in the GLOBAL Cartesian system. |

*INITIAL_STRAIN_TSHELL

Purpose: Initialize the strain tensors for thick shell elements.

Strain tensors are defined at the inner and outer integration points and are used for post-processing only. Strain tensors are defined in the global Cartesian coordinate system. The STRFLG flag on *DATABASE_EXTENT_BINARY must be set to unity for this keyword to work. Initialize as many elements as needed.

Card Sets. For each element, include a set of Cards 1, 2, and 3, where Card 2 is for the inner layer and Card 3 is for the outer layer. The input is assumed to terminate when a new keyword (*) card is detected.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | EID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

Strain Cards. Card 2 is the strain at the inner layer. Card 3 is the strain at the outer layer.

| Cards 2, 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|------------|-------|-------|-------|-------|-------|-------|---|---|
| Variable | EPSxx | EPSyy | EPSzz | EPSxy | EPSyz | EPSzx | | |
| Type | F | F | F | F | F | F | | |
| Default | 0 | 0 | 0 | 0 | 0 | 0 | . | |

| VARIABLE | DESCRIPTION |
|-------------------|--|
| EID | Element ID. |
| EPS _{ij} | Define the <i>ij</i> th strain component. The strains are defined in the global cartesian system. |

***INITIAL_STRESS_BEAM**

Purpose: Initialize stresses, plastic strains and history variables for Hughes-Liu beam elements, or the axial force, moment resultants and history variables for Belytschko-Schwer beam elements and discrete beams.

Card Summary:

Card Sets. Define as many beams in this section as desired. Each set consists of one Card 1 and several additional cards depending on variables NPTS, LARGE, NHISV, and NAXES. The input terminates when a new keyword ("*") card is detected.

Card 1. This card is required.

| | | | | | | | |
|-----|------|------|-------|-------|-------|-------|--|
| EID | RULE | NPTS | LOCAL | LARGE | NHISV | NAXES | |
|-----|------|------|-------|-------|-------|-------|--|

Card 2a. This card is included for Belytschko-Schwer beams if LARGE = 0.

| | | | | | | | |
|-----|-----|-----|-----|-----|-----|------|--|
| F11 | T11 | M12 | M13 | M22 | M23 | PARM | |
|-----|-----|-----|-----|-----|-----|------|--|

Card2b.1. This card is included for Belytschko-Schwer beams if LARGE = 1.

| | | | | | | | |
|-----|-----|-----|-----|-----|--|--|--|
| F11 | T11 | M12 | M13 | M22 | | | |
|-----|-----|-----|-----|-----|--|--|--|

Card2b.2. This card is included for Belytschko-Schwer beams if LARGE = 1. Include additional cards of this format to include all of the history variables.

| | | | | | | | |
|-----|------|-------|-------|-------|--|--|--|
| M23 | PARM | HISV1 | HISV2 | HISV3 | | | |
|-----|------|-------|-------|-------|--|--|--|

Card 2c. Include this card NPTS times for Hughes-Liu beams if LARGE = 0.

| | | | | | | | |
|-------|-------|-------|-------|-------|-------|-----|--|
| SIG11 | SIG22 | SIG33 | SIG12 | SIG23 | SIG31 | EPS | |
|-------|-------|-------|-------|-------|-------|-----|--|

Card 2d.1. Include NPTS sets of this card and Card 2d.2 for Hughes-Liu beams if LARGE = 1.

| | | | | | | | |
|-------|-------|-------|-------|-------|--|--|--|
| SIG11 | SIG22 | SIG33 | SIG12 | SIG23 | | | |
|-------|-------|-------|-------|-------|--|--|--|

Card 2d.2. For each of the NPTS sets include additional cards of this format to include all of the history variables.

| | | | | | | | |
|-------|-----|-------|-------|-------|--|--|--|
| SIG31 | EPS | HISV1 | HISV2 | HISV3 | | | |
|-------|-----|-------|-------|-------|--|--|--|

Card 3.1. This card is included if and only if NAXES = 12.

| | | | | | | | |
|-----|-----|-----|-----|-----|--|--|--|
| AX1 | AX2 | AX3 | AX4 | AX5 | | | |
|-----|-----|-----|-----|-----|--|--|--|

Card 3.2. This card is included if and only if NAXES = 12.

| | | | | |
|-----|-----|-----|-----|------|
| AX6 | AX7 | AX8 | AX9 | AX10 |
|-----|-----|-----|-----|------|

Card 3.3. This card is included if and only if NAXES = 12.

| | | | | |
|------|------|--|--|--|
| AX11 | AX12 | | | |
|------|------|--|--|--|

| | | | | | | | | |
|----------|------|------|------|-------|-------|-------|-------|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | EID | RULE | NPTS | LOCAL | LARGE | NHISV | NAXES | |
| Type | I | I | I | I | I | I | I | |
| Default | none | 2 | none | 0 | 0 | 0 | 0 | |

VARIABLE

DESCRIPTION

EID

Element ID

RULE

Integration rule type number:

EQ.1: 1 × 1 Gauss quadrature,

EQ.2: 2 × 2 Gauss quadrature (default beam),

EQ.3: 3 × 3 Gauss quadrature,

EQ.4: 3 × 3 Lobatto quadrature,

EQ.5: 4 × 4 Gauss quadrature.

NPTS

Number of integration points. For the Belytschko-Schwer resultant beam element, NPTS = 1.

LOCAL

Coordinate system for stresses:

EQ.0: Stress components are defined in the global coordinate system.

EQ.1: Stress components are defined in the local beam system. In the local system components SIG22, SIG33, and SIG23 are set to 0.0.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| LARGE | Format size: EQ.0: off, EQ.1: on. Each field is twice as long for higher precision. |
| NHISV | Number of additional history variables. Only available for LARGE = 1. |
| NAXES | Number of variables giving beam local axes (0 or 12) |

Belytschko-Schwer Card for LARGE = 0. Additional card for the Belytschko-Schwer beam.

| Card 2a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-----|-----|------|---|
| Variable | F11 | T11 | M12 | M13 | M22 | M23 | PARM | |
| Type | F | F | F | F | F | F | F | |

Belytschko-Schwer Cards for LARGE = 1. Additional cards for the Belytschko-Schwer beam. Include as many cards as necessary to collect NHISV (see Card 1) history variables.

| Card 2b.1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|-----------|-----|---|-----|---|-----|---|-----|---|-----|----|
| Variable | F11 | | T11 | | M12 | | M13 | | M22 | |
| Type | F | | F | | F | | F | | F | |

| Card 2b.2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|-----------|-----|---|------|---|-------|---|-------|---|-------|----|
| Variable | M23 | | PARM | | HISV1 | | HISV2 | | HISV3 | |
| Type | F | | F | | F | | F | | F | |

Hughes-Liu Cards for LARGE = 0. Additional cards for the Hughes-Liu beam. Include NPTS additional cards, one per integration point.

| Card 2c | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|-------|-------|-------|-----|---|
| Variable | SIG11 | SIG22 | SIG33 | SIG12 | SIG23 | SIG31 | EPS | |
| Type | F | F | F | F | F | F | F | |

Hughes-Liu Cards for LARGE = 1. Additional cards for the Hughes-Liu beam. Include NPTS additional card sets, one per integration point. Include as many cards in one card set as necessary to collect NHISV (see Card 1) history variables.

| Card 2d.1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|-----------|-------|---|-------|---|-------|---|-------|---|-------|----|
| Variable | SIG11 | | SIG22 | | SIG33 | | SIG12 | | SIG23 | |
| Type | F | | F | | F | | F | | F | |

| Card 2d.2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|-----------|-------|---|-----|---|-------|---|-------|---|-------|----|
| Variable | SIG31 | | EPS | | HISV1 | | HISV2 | | HISV3 | |
| Type | F | | F | | F | | F | | F | |

VARIABLE**DESCRIPTION**

| | |
|----------|--|
| F11 | Axial force resultant along local beam axis 1 |
| T11 | Torsional moment resultant about local beam axis 1 |
| M12 | Moment resultant at node 1 about local beam axis 2 |
| M13 | Moment resultant at node 1 about local beam axis 3 |
| M22 | Moment resultant at node 2 about local beam axis 2 |
| M23 | Moment resultant at node 2 about local beam axis 3 |
| PARM | Generally not used. |
| SIG ij | Define the ij stress component |

| VARIABLE | DESCRIPTION |
|-----------------|------------------------------------|
| EPS | Effective plastic strain |
| HISV n | Define the n th history variable |

Optional Local Axes Cards for NAXES = 12. Additional cards for definition of local axes values. These 12 values are internally used by LS-DYNA for the mapping between local beam element system and global coordinate system. They are automatically written to the dynain file if *INTERFACE_SPRINGBACK_LSDYNA or *CONTROL_-STAGED_CONSTRUCTION is used.

| Card 3.1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|-----|---|-----|---|-----|---|-----|---|-----|----|
| Variable | AX1 | | AX2 | | AX3 | | AX4 | | AX5 | |
| Type | F | | F | | F | | F | | F | |

| Variable | AX11 | | AX12 | | | | | | | |
| Type | F | | F | | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|-----------------------------|
| AX n | The n th local axes value |

*INITIAL_STRESS_DEPTH_{OPTION}

Available options include:

<BLANK>

SET

Purpose: Initialize solid element stresses where stress is a function of depth.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|------|--------|-------|-----|-----|------|---|
| Variable | PID/PSID | RO_G | ZDATUM | KFACT | LC | LCH | LCK0 | |
| Type | I | F | F | F | I | I | I | |
| Default | none | none | none | 0.0 | opt | opt | opt | |

VARIABLE

DESCRIPTION

| | |
|----------|---|
| PID/PSID | Part ID or Part Set ID for the SET option |
| RO_G | Stress per unit elevation above datum, which is usually $\rho_g = \text{density} \times \text{gravity}$. |
| ZDATUM | z-coordinate of datum |
| KFACT | x and y-stresses = KFACT × z-stress |
| LC | Optional curve of stress as a function of the z-coordinate (ZDATUM is ignored with this option) |
| LCH | Optional curve of horizontal stress as function of the z-coordinate (KFACT is ignored with this option) |
| LCK0 | Optional curve of K0 (ratio of horizontal stress to vertical stress) as a function z-coordinate. KFACT and LCH are ignored with this option. The x-axis of the curve is the z-coordinate, the y-axis is K0. |

Remarks:

- Model Description.** With this keyword stress is calculated according to,

$$\sigma_z = RO_G \times (Z_{\text{element}} - Z_{\text{DATUM}}) ,$$

where Z_{element} is the z -coordinate of the centroid of the element. It is assumed that the z -axis points vertically upwards. For a 2D problem (axisymmetric or plane strain), replace z in this documentation with y . To generate compressive stresses, the datum should be above the highest element, that is, the datum should have a more positive z -coordinate. For instance, this is at the surface of the soil in geotechnics simulations. If the curve, LC , is defined, it overrides RO_G and Z_{DATUM} . Note that the points in the curve should be ordered with most negative z -coordinate first.

2. **Pore Water.** If pore water is present, the stresses input here are effective (soil skeleton stresses only). The pore water pressures will automatically be initialized to hydrostatic or by `*INITIAL_PWP_DEPTH` or `*BOUNDARY_PWP_TABLE` if those cards are present.
3. **Stress at Integration Points.** For fully-integrated elements, the stress calculated for the element centroid is applied at all the integration points. There is no stress gradation up the height of the element. This is to ensure equilibrium with gravity loading, which is applied at the nodes and therefore results in stress that is uniformly distributed up the height of the element.

***INITIAL_STRESS_SECTION**

Purpose: Initialize (pre-load) the stress normal to a plane intersecting the model using a curve ([*DEFINE_CURVE](#)). The initialization is applied to a set of solid elements that are specified using the [*DATABASE_CROSS_SECTION](#) card. This option is compatible only with those material models that are incrementally updated (such as elastic, viscoelastic, and elastoplastic). Except as noted in [Remark 3](#), rubbers, foams, and materials that are combined with equations-of-state cannot be initialized with this card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|------|------|------|------|---------|---|---|
| Variable | ISSID | CSID | LCID | PSID | VID | IZSHEAR | | |
| Type | I | I | I | I | I | I | | |
| Default | none | none | none | none | none | 0 | | |

VARIABLE**DESCRIPTION**

| | |
|-------|--|
| ISSID | ID for this card. |
| CSID | Cross-section ID. See *DATABASE_CROSS_SECTION . |
| LCID | Load curve ID defining preload stress as a function of time. When the load curve ends or goes to zero, the initialization is assumed to be completed. See Remark 2 . |
| PSID | Part set ID. Stress is initialized on only those parts included in <i>both</i> PSID from this card and the PSID field from the associated *DATABASE_CROSS_SECTION card. |
| VID | Vector ID (see *DEFINE_VECTOR) specifies the direction normal to the cross section (CSID). VID <i>must</i> be set when the "SET" variant of *DATABASE_CROSS_SECTION (*DATABASE_CROSS_SECTION_SET) is used. If the cross section is defined using the PLANE option, the normal used in the definition of the plane is used when VID is left undefined. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| IZSHEAR | Shear stress flag: EQ.0: Shear stresses are prescribed as zero during the time the curve is acting to prescribe normal stress. EQ.1: Shear stresses are allowed to develop during the time the curve is acting to prescribe normal stress. For implicit the section can also take bending and is the same as 2, see remarks. EQ.2: Shear and bending stresses are allowed to develop during the time the curve is acting to prescribe normal stress, see remarks. |

Remarks:

1. **Dynamic Relaxation Issues.** To achieve convergence during explicit dynamic relaxation, the application of the damping options is very important. If contact is active, contact damping is recommended with a value between 10-20 percent. Additional damping, via the option [*DAMPING_PART_STIFFNESS](#) also speeds convergence where a coefficient of 0.10 is effective. If damping is not used, convergence may not be possible.
2. **Best Practices for Quasi-Static Load Ramp-up.** When defining the load curve, LCID, a ramp starting at the origin should be used to increase the stress to the desired value. The time duration of the ramp should produce a quasi-static response. When the end of the load curve is reached, or when the value of the load decreases from its maximum value, the initialization stops. If the load curve begins at the desired stress value, i.e., no ramp, convergence will take much longer, since the impulsive like load created by the initial stress can excite nearly every frequency in the structural system where stress is initialized.
3. **Supported Materials.** This option currently applies only to materials that are incrementally updated. Hyperelastic materials and materials that require an equation-of-state are not currently supported. However, materials 57, 73, and 83 can be initialized with this approach.
4. **Supported Elements.** Solid elements types 1, 2, 3, 4, 9, 10, 13, 15, 16, 17, and 18 are supported. ALE elements are not supported.
5. **IZSHEAR for Solid Elements.** By default, IZSHEAR=0, and *only* the stress normal to the section is prescribed while *all* other stress components are set to zero. That is, the stress tensor components with respect to a local system

aligned with the section would have $\sigma_{xx} = \sigma$ (the prescribed value) and $\sigma_{yy} = \sigma_{zz} = \sigma_{xy} = \sigma_{xz} = \sigma_{yz} = 0$, which holds for each integration point of each element in the section. This in turn means that these elements, thus the entire section, are infinitely weak in bending and shear and a potential side effect might be unexpected and nonsensical deformations if loading conditions and surrounding geometry allow this. Turning on IZSHEAR=1 will for *explicit analysis* essentially relax the zero constraint on the shear stresses, resulting in a stress tensor where σ_{xy} , σ_{xz} and σ_{yz} are updated according to the laws of the material model, thus adding some shear stiffness to the section to avoid spurious deformations.

For *implicit analysis*, and currently only the low order element formulations -1, -2, 1, 2, 10, 13, 15 and 115, the following approach is taken for IZSHEAR=1. Each collection of elements in a section (*e.g.*, of a bolt) is identified and seen as an entity for which only the *mean normal stress* of the section is prescribed, in contrast to imposing constraints on each integration point. For example, if a goal is to pre-stress say 10 bolts modeled with solid elements, LS-DYNA will based on element connectivity identify the 10 unique sections (10 clusters of elements) corresponding to each bolt, and subsequently prescribe the mean stress in each of these sections independently. The advantage with this approach is that the section can globally resist bending and shear, and thus preserve the structural integrity of the bolt more adequately.

For explicit analysis, this latter approach is available through IZSHEAR=2.

***INITIAL_STRESS_SHELL_{OPTION}**

Available options include:

<BLANK>

SET

Purpose: Initialize stresses, history variables, and the effective plastic strain for shell elements. Materials that do not use an incremental formulation for the stress update may not be initializable with this card.

Card Sets per Element. Define as many shell elements or shell element sets in this section as desired. The input is assumed to terminate when a new keyword ("**") card is detected.

Element Card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---------|--------|--------|-------|--------|-------|--------|--------|
| Variable | EID/SID | NPLANE | NTHICK | NHISV | NTENSR | LARGE | NTHINT | NTHHSV |
| Type | I | I | I | I | I | I | I | I |
| Default | none | none | none | 0 | 0 | 0 | 0 | 0 |

Ordering of Integration Points.

For each through thickness point define NPLANE points. NPLANE should be either 1 or 4 corresponding to either 1 or 4 Gauss integration points. If four integration points are specified, they should be ordered such that their in-plane parametric coordinates are at:

$$\left(-\frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}\right), \quad \left(\frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}\right), \quad \left(\frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3}\right), \quad \left(-\frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3}\right),$$

respectively. It is not necessary for the location of the through thickness integration points to match those used in the elements which are initialized. The data will be interpolated by LS DYNA.

Solid Mechanics Data Card for LARGE = 0.

The following set of cards, "Stress Card" through "Tensor Cards," should be included NPLANE × NTHICK times (one set for each integration point).

Stress Card. Additional Card for LARGE = 0.

| | | | | | | | | |
|----------|---|-------|-------|-------|-------|-------|-------|-----|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | T | SIGXX | SIGYY | SIGZZ | SIGXY | SIGYZ | SIGZX | EPS |
| Type | F | F | F | F | F | F | F | F |

History Variable Cards. Additional Cards for LARGE = 0. Include as many cards as necessary to collect NHISV (see Card 1) history variables.

| | | | | | | | | |
|----------|-------|-------|-------|-------|-------|-------|-------|-------|
| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | HISV1 | HISV2 | HISV3 | HISV4 | HISV5 | HISV6 | HISV7 | HISV8 |
| Type | F | F | F | F | F | F | F | F |

Tensor Cards. Additional card for LARGE = 0. Include as many cards as necessary to collect NTENSR (see Card 1) entries. Tensor cards contain only 6 entries per card.

| | | | | | | | | |
|----------|-------|-------|-------|-------|-------|-------|---|---|
| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | TENXX | TENYY | TENZZ | TENXY | TENYZ | TENZX | | |
| Type | F | F | F | F | F | F | | |

Solid Mechanics Data Card for LARGE = 1.

The following set of cards, "Stress Card 1" through "Tensor Cards," should be included NPLANE × NTHICK times (one set for each integration point).

Stress Card 1. Additional Card for LARGE = 1.

| | | | | | | | | | | |
|----------|---|---|-------|---|-------|---|-------|---|-------|----|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| Variable | T | | SIGXX | | SIGYY | | SIGZZ | | SIGXY | |
| Type | F | | F | | F | | F | | F | |

Stress Card 2. Additional Card for LARGE = 1.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|-------|---|-------|---|-----|---|---|---|---|----|
| Variable | SIGYZ | | SIGZX | | EPS | | | | | |
| Type | F | | F | | F | | | | | |

History Variable Cards. Additional Cards for LARGE = 1. Include as many cards as necessary to collect NHISV (see Card 1) history variables.

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|-------|---|-------|---|-------|---|-------|---|-------|----|
| Variable | HISV1 | | HISV2 | | HISV3 | | HISV4 | | HISV5 | |
| Type | F | | F | | F | | F | | F | |

Tensor Cards. Include as many pairs of Cards 5 and 6 as necessary to collect NTENSR entries. Note that Cards 5 and 6 must appear as pairs, and that Card 6 may include at most one value, as indicated below.

| Card 5 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|-------|---|-------|---|-------|---|-------|---|-------|----|
| Variable | TENXX | | TENYY | | TENZZ | | TENXY | | TENYZ | |
| Type | F | | F | | F | | F | | F | |

| Card 6 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|-------|---|---|---|---|---|---|---|---|----|
| Variable | TENZX | | | | | | | | | |
| Type | F | | | | | | | | | |

Thermal Data Cards for LARGE = 1.

For each element, thermal data cards come after the *entire* set of mechanical data cards. For each of the NTHINT thermal integration points, include the following set of cards.

Thermal Time History Cards. Additional cards for LARGE = 1. Include as many cards as needed to collect all the of NTHHSV time history variables per thermal integration point.

| Card 7 | 1 | 2 | 3 | 4 | 5 |
|----------|--------|--------|--------|--------|--------|
| Variable | THHSV1 | THHSV2 | THHSV3 | THHSV4 | THHSV5 |
| Type | F | F | F | F | F |

VARIABLE**DESCRIPTION**

| | |
|----------|--|
| EID/SID | Element ID or shell set ID, see *SET_SHELL_... |
| NPLANE | Number of in plane integration points being output. |
| NTHICK | Number of integration points through the thickness. |
| NHISV | Number of additional history variables. |
| NTENSR | Number of components of tensor data taken from the element history variables stored. |
| LARGE | Format size. See cards above. EQ.0: off EQ.1: on |
| T | Parametric coordinate of through thickness integration point between -1 and 1 inclusive. |
| SIG ij | Define the ij stress component. The stresses are defined in the GLOBAL cartesian system. |
| EPS | Effective plastic strain. |
| HISV n | Define the n^{th} history variable. |
| TEN ij | Define the ij^{th} component of the tensor taken from the history variables. The tensor is defined in the GLOBAL Cartesian system. Define enough lines to provide a total of NTENSOR components, stored six components per line. This applies to material 190 only. |
| NTHINT | Number of thermal integration points. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| NTHHSV | Number of thermal history variables per thermal integration point. |
| THHSV n | n^{th} history variable at the thermal integration point. |

*INITIAL_STRESS_SHELL_NURBS_PATCH

Purpose: Initialize stresses, history variables, and the effective plastic strain for isogeometric shell elements. Materials that do not use an incremental formulation for the stress update may not be initializable with this card.

Card Sets per Element. Define as many NURBS shell elements in this section as desired. The input is assumed to terminate when a new keyword ("**") card is detected.

Element Card.

| | | | | | | | | |
|----------|------|--------|--------|-------|-------|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | EID | NPLANE | NTHICK | NHISV | LARGE | | | |
| Type | I | I | I | I | I | | | |
| Default | none | none | none | 0 | 0 | | | |

Solid Mechanics Data Card for LARGE = 0.

The following set of cards: "Stress Cards" and "History Variable Cards" should be included NPLANE x NTHICK times (one set for each integration point).

Stress Card1. Additional Card for LARGE = 0.

| | | | | | | | | |
|----------|---|---|---|---|---|---|---|---|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | R | S | T | | | | | |
| Type | F | F | F | | | | | |

Stress Card2. Additional Card for LARGE = 0.

| | | | | | | | | |
|----------|-------|-------|-------|-------|-------|-------|------|---|
| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | SIGXX | SIGYY | SIGZZ | SIGXY | SIGYZ | SIGZX | EPSP | |
| Type | F | F | F | F | F | F | F | |

History Variable Cards. Additional Cards for LARGE = 0. Include as many cards as necessary to collect NHISV (see Card 1) history variables.

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|-------|-------|-------|-------|-------|
| Variable | HISV1 | HISV2 | HISV3 | HISV4 | HISV5 | HISV6 | HISV7 | HISV8 |
| Type | F | F | F | F | F | F | F | F |

Solid Mechanics Data Card for LARGE = 1.

The following set of cards: "Stress Cards" and "History Variable Cards" should be included NPLANE × NTHICK times (one set for each integration point).

Stress Card 1. Additional Card for LARGE = 1.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|---|---|---|---|---|---|-------|---|-------|----|
| Variable | R | | S | | T | | SIGXX | | SIGYY | |
| Type | F | | F | | F | | F | | F | |

Stress Card 2. Additional Card for LARGE = 1.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|-------|---|-------|---|-------|---|-------|---|-----|----|
| Variable | SIGZZ | | SIGXY | | SIGYZ | | SIGZX | | EPS | |
| Type | F | | F | | F | | F | | F | |

History Variable Cards. Additional Cards for LARGE = 1. Include as many cards as necessary to collect NHISV (see Card 1) history variables.

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|-------|---|-------|---|-------|---|-------|---|-------|----|
| Variable | HISV1 | | HISV2 | | HISV3 | | HISV4 | | HISV5 | |
| Type | F | | F | | F | | F | | F | |

| VARIABLE | DESCRIPTION |
|-------------|---|
| EID | NURBS Element ID |
| NPLANE | Number of in plane integration points being output. |
| NTHICK | Number of integration points through the thickness. |
| NHISV | Number of additional history variables. |
| LARGE | Format size. See cards above. EQ.0: off EQ.1: on |
| R | Parametric r -coordinate of location of in-plane integration point (with respect to NURBS-patch definition) |
| S | Parametric s -coordinate of location of in-plane integration point (with respect to NURBS-patch definition) |
| T | Parametric coordinate of through thickness integration point between -1 and 1 inclusive. |
| SIG $_{ij}$ | Define the ij stress component. The stresses are defined in the GLOBAL cartesian system. |
| EPS | Effective plastic strain. |
| HISV $_n$ | Define the n^{th} history variable. |

***INITIAL_STRESS_SOLID_{OPTION}**

Available options include:

<BLANK>

SET

Purpose: Initialize stresses and plastic strains for solid elements. This command is not applicable to hyperelastic materials or any material model based on a Total Lagrangian formulation. Furthermore, for *MAT_014 and any material that requires an equation-of-state (*EOS), the specified initial stresses are adjusted to be in accordance with the initial pressure calculated from the equation of state.

Card Sets per Element or Element Set. For this keyword, each data card set consists of an element or element set card and all of its corresponding data cards, both thermal and mechanical. For LARGE = 1, this can involve several (even tens of) cards per set. Include cards for as many solid elements or solid element sets as desired. The input is assumed to terminate when a new keyword ("*") card is detected.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---------|------|-------|-------|--------|--------|--------|--------|
| Variable | EID/SID | NINT | NHISV | LARGE | IVEFLG | IALEGP | NTHINT | NTHHSV |
| Type | I | I | I | I | I | I | I | I |
| Default | none | none | 0 | 0 | 0 | 0 | 0 | 0 |

Ordering of Integration Points.

NINT may be 1, 8, or 14 for hexahedral solid elements, depending on the element formulation. If eight Gauss integration points are specified, they should be ordered such that their parametric coordinates are located at:

$$\left(-\frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}\right), \left(\frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}\right), \left(\frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}\right), \left(-\frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}\right),$$

$$\left(-\frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3}\right), \left(\frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3}\right), \left(\frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3}\right), \left(-\frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3}\right),$$

respectively. If eight points are defined for 1 point LS-DYNA solid elements, the average value will be taken.

NINT may be 1, 4, or 5 for tetrahedral solid elements, depending on the element formulation and NIP TETS in *CONTROL_SOLID. NINT may be 1 or 2 for pentahedral solid elements, depending on the element formulation.

Solid Mechanics Data Card for LARGE = 0.

Stress Card. Additional Card for LARGE = 0. This card should be included NINT times (one for each integration point).

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|-------|-------|-------|-----|---|
| Variable | SIGXX | SIGYY | SIGZZ | SIGXY | SIGYZ | SIGZX | EPS | |
| Type | F | F | F | F | F | F | F | |

Mechanical Data Cards for LARGE = 1.

The following set of cards "Stress Card 1" through "Additional History Cards." Should be included NINT times (one set for each integration point).

Stress Card 1. Additional cards for LARGE = 1.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|-------|---|-------|---|-------|---|-------|---|-------|----|
| Variable | SIGXX | | SIGYY | | SIGZZ | | SIGXY | | SIGYZ | |
| Type | F | | F | | F | | F | | F | |

Stress Card 2. Additional cards for LARGE = 1.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|-------|---|-----|---|-------|---|-------|---|-------|----|
| Variable | SIGZX | | EPS | | HISV1 | | HISV2 | | HISV3 | |
| Type | F | | F | | F | | F | | F | |

Additional History Cards. Additional cards for LARGE = 1. If NHISV > 3 define as many additional cards as necessary. NOTE: the value of IVEFLG (see Card 1) can affect the number of history variables on these cards.

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|-------|---|-------|---|-------|---|-------|---|-------|----|
| Variable | HISV4 | | HISV5 | | HISV6 | | HISV7 | | HISV8 | |
| Type | F | | F | | F | | F | | F | |

Thermal Data Cards for LARGE = 1.

For each element, thermal data cards come after the *entire* set of mechanical data cards. For each of the NTHINT thermal integration points, include the following set of cards.

Thermal Time History Cards. Additional cards for LARGE = 1. Include as many cards as needed to capture all the of NTHHSV time history variables per thermal integration point.

| Card 5 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|--------|---|--------|---|--------|---|--------|---|--------|----|
| Variable | THHSV1 | | THHSV2 | | THHSV3 | | THHSV4 | | THHSV5 | |
| Type | F | | F | | F | | F | | F | |

VARIABLE

DESCRIPTION

| | |
|---------|--|
| EID/SID | Element ID or solid set ID; see *SET_SOLID_... |
| NINT | Number of integration points (should correspond to the solid element formulation). |
| NHISV | Number of additional history variables, which is typically equal to the number of history variables stored at the integration point + IVEFLG. |
| LARGE | Format size. If zero, NHISV must also be set to zero (this is the format used by LS-DYNA versions 970 and earlier), and, if set to 1, a larger format is used and NHISV is used. |

| VARIABLE | DESCRIPTION |
|--------------------|---|
| IVEFLG | <p>Initial Volume/energy flag (only used in large format):</p> <p>EQ.0: Last history variable is used as normal.</p> <p>EQ.1: Last history variable is used as the initial volume of the element. One additional history variable is required if IVEFLG = 1.</p> <p>EQ.2: Last two history variables are used to define the initial volume and the internal energy per unit initial volume. Two additional history variables must be allocated; see NHISV above, if IVEFLG = 2. If the initial volume is set to zero, the actual element volume is used.</p> |
| IALEGP | <p>The ALE multi-material group (AMMG) ID; only if the element is of ALE multi-material formulation (ELFORM = 11). In this case, each AMMG has its own sets of stress and history variables, so we must specify to which AMMG the stress data are assigned. For mixed elements, multiple cards are needed to complete the stress initialization in this element as each AMMG needs to have its own set of stress data.</p> <p>EQ.0: Assuming the element is fully filled by the AMMG that the element part belongs to. Please refer to *ALE_MULTI-MATERIAL_GROUP card.</p> <p>EQ.n: Assigning the stress to nth AMMG in that element.</p> |
| SIG _{ij} | <p>Define the <i>ij</i>th stress component. Stresses are defined in the GLOBAL Cartesian system.</p> |
| EPS | <p>Effective plastic strain</p> |
| HISV _i | <p>Define NHISV history variables.</p> |
| NTHINT | <p>Number of thermal integration points</p> |
| NTHHSV | <p>Number of thermal history variables per thermal integration point</p> |
| THHSV _n | <p><i>n</i>th thermal time history variable</p> |

Remarks:

1. **Cohesive Elements.** The elastic material model for cohesive elements is a total Lagrangian formulation, and the initial stress will therefore be ignored for it.

*INITIAL_STRESS_SOLID_NURBS_PATCH

Purpose: Initialize stresses, effective plastic strain and history variables for isogeometric solid elements. This command is not applicable to hyperelastic materials or any material model based on a Total Lagrangian formulation.

Card Sets. Define as many NURBS solid elements in this section as desired, one set of cards per element. The input is assumed to terminate when a new keyword ("*") card is detected.

| | | | | | | | | |
|----------|------|------|-------|-------|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | EID | NINT | NHISV | LARGE | | | | |
| Type | I | I | I | I | | | | |
| Default | none | none | 0 | 0 | | | | |

Solid Mechanics Data Card for LARGE = 0.

The following set of cards, "Stress Cards" and "History Variable Cards" should be included NINT times (one set for each integration point).

Stress Card1. Additional card for LARGE = 0.

| | | | | | | | | |
|----------|---|---|---|---|---|---|---|---|

| VARIABLE | DESCRIPTION |
|-----------------|---|
| EID | NURBS Element ID |
| NINT | Number of in integration points being output. |
| NHISV | Number of additional history variables. |
| LARGE | Format size: EQ.0: off EQ.1: on |
| R | Parametric r -coordinate of location of in-plane integration point (with respect to NURBS patch definition) |
| S | Parametric s -coordinate of location of in-plane integration point (with respect to NURBS patch definition) |
| T | Parametric t -coordinate of location of in-plane integration point (with respect to NURBS patch definition) |
| SIG $_{ij}$ | Define the ij stress component. The stresses are defined in the GLOBAL cartesian system. |
| EPS | Effective plastic strain. |
| HISV $_n$ | Define the n^{th} history variable. |

***INITIAL_STRESS_SPH**

Purpose: Initialize stresses and plastic strains for SPH elements. This command is not applicable to hyperelastic materials or any material model based on a Total Lagrangian formulation. For *MAT_005, *MAT_014, and any material that requires an equation-of-state (*EOS), the initialized stresses are deviatoric stresses, not total stresses.

Element Cards. Define as many SPH elements in this section as desired. The input is assumed to terminate when a new keyword is detected.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|-------|-------|-------|-------|-------|------|
| Variable | EID | SIGXX | SIGYY | SIGZZ | SIGXY | SIGYZ | SIGZX | EPS |
| Type | I | F | F | F | F | F | F | F |
| Default | none | none | none | none | none | none | none | none |

VARIABLE**DESCRIPTION**

| | |
|----------|--|
| EID | SPH particle ID |
| SIG ij | Define the ij^{th} stress component. Stresses are defined in the GLOBAL Cartesian system. |
| EPS | Effective plastic strain. |

*INITIAL_STRESS_TSHELL

Purpose: Initialize stresses and plastic strains for thick shell elements.

Card Sets per Element. Define as many thick shell elements in this section as desired. The input is assumed to terminate when a new keyword is detected.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|--------|-------|-------|---|---|---|

| Default | none | none | none | 0 | 0 | | | |

Ordering of Integration Points.

For each through thickness point define NPLANE points. NPLANE should be either 1 or 4 corresponding to either 1 or 4 Gauss integration points. If four integration points are specified, they should be ordered such that their in plane parametric coordinates are at:

$$\left(-\frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}\right), \quad \left(\frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}\right), \quad \left(\frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3}\right), \quad \left(-\frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3}\right)$$

respectively. It is not necessary for the location of the through thickness integration points to match those used in the elements which are initialized. The data will be interpolated by LS DYNA.

Data Card for LARGE = 0.

The following set of cards "Stress Card" and "History Cards." Should be included NPLANE x NTHICK times (one set for each integration point).

Stress Card. Additional card for LARGE = 0.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---|-------|-------|-------|-------|-------|-------|-----|
| Variable | T | SIGXX | SIGYY | SIGZZ | SIGXY | SIGYZ | SIGZX | EPS |
| Type | F | F | F | F | F | F | F | F |

History Cards. Additional Card for LARGE = 0. Include as many History Cards as needed to define all NHIST history variables.

| Optional | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|-------|-------|-------|-------|-------|
| Variable | HISV1 | HSIV2 | HSIV3 | HSIV4 | HSIV5 | HSIV6 | HSIV7 | HSIV8 |
| Type | F | F | F | F | F | F | F | F |

Data Card for LARGE = 1.

The following set of cards “Stress Cards” and “History Cards.” Should be included NPLANE × NTHICK times (one set for each integration point).

Stress Card 1. Additional card for LARGE = 1.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|---|-------|---|-------|---|-------|---|-------|---|----|
| Variable | T | SIGXX | | SIGYY | | SIGZZ | | SIGXY | | |

| Variable | SIGYZ | | SIGZX | | EPS | | | | | |
| Type | F | | F | | F | | | | | |

History Cards. Additional Card for LARGE = 1. Include as many History Cards as needed to define all NHIST history variables.

| Optional | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|-------|---|-------|---|-------|---|-------|---|-------|----|
| Variable | HISV1 | | HISV2 | | HISV3 | | HISV4 | | HISV5 | |
| Type | F | | F | | F | | F | | F | |

| VARIABLE | DESCRIPTION |
|-------------------|---|
| EID | Element ID |
| NPLANE | Number of in plane integration points. |
| NTHICK | Number of integration points through the thickness. |
| T | Parametric coordinate of through thickness integration point between -1 and 1 inclusive. |
| NHISV | Number of additional history variables. |
| LARGE | Format size. See keywords above. EQ.0: off EQ.1: on |
| SIG _{ij} | Define the <i>ij</i> stress component. The stresses are defined in the GLOBAL Cartesian system. |
| EPS | Effective plastic strain |

***INITIAL_TEMPERATURE_OPTION**

Available options include:

NODE

SET

Purpose: Define initial nodal point temperatures using nodal set IDs or node numbers. These initial temperatures are used in a thermal only analysis or a coupled thermal/structural analysis. See also *CONTROL_THERMAL_SOLVER, *CONTROL_THERMAL_TIMESTEP, and CONTROL_THERMAL_NONLINEAR.

For thermal loading in a structural only analysis, see *LOAD_THERMAL_OPTION.

Node/Node set Cards. Include one card for each node or node set. This input ends at the next keyword ("*") keyword.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|------|-----|---|---|---|---|---|
| Variable | NSID/NID | TEMP | LOC | | | | | |
| Type | I | I | I | | | | | |
| Default | ↓ | 0. | 0 | | | | | |
| Remarks | 1 | | | | | | | |

VARIABLE**DESCRIPTION**

NSID/NID

Nodal set ID or nodal point ID, see also *SET_NODES:

EQ.0: all nodes are included (set option only).

TEMP

Temperature at node or node set.

LOC

For a thick thermal shell, the temperature will be applied to the surface identified by LOC. See parameter, THSHEL, on the *CONTROL_SHELL keyword.

EQ.-1: lower surface of thermal shell element

EQ.0: middle surface of thermal shell element

EQ.1: upper surface of thermal shell element

Remarks:

1. **SPH Particles.** This keyword can be used to define initial nodal point temperatures for SPH particles by using nodal set IDs or node numbers from SPH particles.

*INITIAL

*INITIAL_TEMPERATURE

*INITIAL_VAPOR_PART

Purpose: Initialization of a part as a vapor material for *PART using *MAT_NULL and *EOS_PHASE_CHANGE. All elements in the part are initialized as a vapor material.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | PID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

VARIABLE

DESCRIPTION

PID

Part ID of the part to be initialized as a vapor material

***INITIAL_VEHICLE_KINEMATICS**

Purpose: Define initial kinematical information for a vehicle. In its initial orientation, the vehicle's yaw, pitch, and roll axes must be aligned with the global axes. Successive simple rotations are taken about these body fixed axes.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|----|----|----|----|----|----|
| Variable | GRAV | PSID | X0 | Y0 | Z0 | XF | YF | ZF |

| Type | F | F | F | F | F | F | | |
| Default | 0. | 0. | 0. | 0. | 0. | 0. | | |

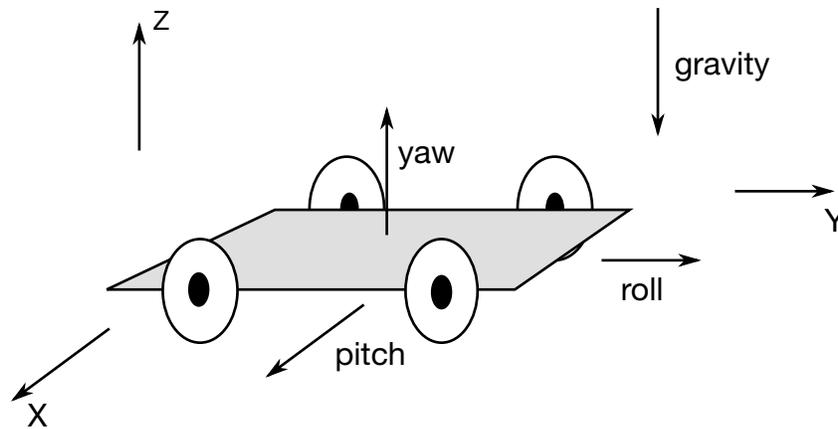

Figure 24-3. The vehicle pictured is to be oriented with a successive rotation sequence about the yaw, pitch, and roll axes, respectively. Accordingly, AAXIS = 3, BAXIS = 1, and CAXIS = 2. The direction of gravity is given by GRAV = -3.

| VARIABLE | DESCRIPTION |
|----------|--|
| GRAV | Gravity direction code. EQ.1: Global + x direction. EQ.-1: Global - x direction. EQ.2: Global + y direction. EQ.-2: Global - y direction. EQ.3: Global + z direction. EQ.-3: Global - z direction. Note: this must be the same for all vehicles present in the model. |
| PSID | Part set ID. |
| XO | x -coordinate of initial position of mass center. |
| YO | y -coordinate of initial position of mass center. |
| ZO | z -coordinate of initial position of mass center. |
| XF | x -coordinate of final position of mass center. |
| YF | y -coordinate of final position of mass center. |
| ZF | z -coordinate of final position of mass center. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| VX | global x -component of mass center velocity. |
| VY | global y -component of mass center velocity. |
| VZ | global z -component of mass center velocity. |
| AAXIS | First rotation axis code. EQ.1: Initially aligned with global x -axis. EQ.2: Initially aligned with global y -axis. EQ.3: Initially aligned with global z -axis. |
| BAXIS | Second rotation axis code. |
| CAXIS | Third rotation axis code. |
| IVADD | Flag for velocity overwrite / add: EQ.1: Add to pre-defined velocities. EQ.2: Overwrite pre-defined velocities (default). |
| AANG | Rotation angle about the first rotation axis (degrees). |
| BANG | Rotation angle about the second rotation axis (degrees). |
| CANG | Rotation angle about the third rotation axis (degrees). |
| WA | Angular velocity component for the x body-fixed axis (radian/second). |
| WB | Angular velocity component for the y body-fixed axis (radian/second). |
| WC | Angular velocity component for the z body-fixed axis (radian/second). |

*INITIAL

*INITIAL_VELOCITY

*INITIAL_VELOCITY

Purpose: Define initial nodal point velocities using nodal set ID's. This may also be used for sets in which some nodes have other velocities. See NSIDEX below.

VARIABLE

DESCRIPTION

NSID

Nodal set ID, see *SET_NODES, containing nodes for initial velocity. If NSID = 0, the initial velocity is applied to all nodes.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| NSIDEX | Nodal set ID, see *SET_NODES, containing nodes that are exempted from the imposed velocities and may have other initial velocities. |
| BOXID | All nodes in box which belong to NSID are initialized. Nodes outside the box are not initialized. Exempted nodes are initialized to velocities defined by VXE, VYE, and VZE below, regardless of their location relative to the box. |
| IRIGID | <p>Option to overwrite rigid body velocities defined on *PART_INERTIA or *CONSTRAINED_NODAL_RIGID_BODY_INERTIA cards.</p> <p>GE.1: part set ID, containing ID of parts to overwrite. Center of gravity of part must lie within box BOXID. If BOXID is not defined, then all parts defined in the set are overwritten.</p> <p>EQ.-1: Overwrite velocities for all rigid bodies defined with *PART_INERTIA or *CONSTRAINED_NODAL_RIGID_BODY_INERTIA that have a center of gravity within box BOXID. If BOXID is not defined, then all are overwritten.</p> <p>EQ.-2: Overwrite velocities for all rigid bodies defined with *PART_INERTIA or *CONSTRAINED_NODAL_RIGID_BODY_INERTIA.</p> |
| ICID | Local coordinate system ID. The initial velocity is specified in the local coordinate system if ICID is greater than zero. Furthermore, if ICID is greater than zero, *INCLUDE_TRANSFORM does not rotate the initial velocity values specified by VX, VY, ..., VZRE. |
| VX | Initial translational velocity in x -direction |
| VY | Initial translational velocity in y -direction |
| VZ | Initial translational velocity in z -direction |
| VXR | Initial rotational velocity about the x -axis |
| VYR | Initial rotational velocity about the y -axis |
| VZR | Initial rotational velocity about the z -axis |
| VXE | Initial velocity in x -direction of exempted nodes |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| VYE | Initial velocity in y -direction of exempted nodes |
| VZE | Initial velocity in z -direction of exempted nodes |
| VXRE | Initial rotational velocity in x -direction of exempted nodes |
| VYRE | Initial rotational velocity in y -direction of exempted nodes |
| VZRE | Initial rotational velocity in z -direction of exempted nodes |

Remarks:

1. **Deck Restrictions.** This generation input must not be used with *INITIAL_VELOCITY_GENERATION keyword.
2. **Multiple Nodal Velocity Initializations.** If a node velocity is initialized on more than one input card set, then the last set input will determine its velocity. However, if the nodal velocity is also specified on a *INITIAL_VELOCITY_NODE card, then the velocity specification on this card will be used.
3. **Overwriting Rigid Body Velocities.** Unless the option IRIGID is specified, initial velocities for rigid bodies given by *PART_INERTIA will overwrite generated initial velocities. The IRIGID option will cause the rigid body velocities specified on the *PART_INERTIA input to be overwritten. To directly specify the motion of a rigid body without using the keyword, *PART_INERTIA, which also requires the definition of the mass properties, use the keyword option, *INITIAL_VELOCITY_RIGID_BODY.
4. **Rigid Body Motion Consistency.** Nodes which belong to rigid bodies must have motion consistent with the translational and rotational velocity of the center of gravity (c.g.) of the rigid body. During initialization the rigid body translational and rotational rigid body momentum's are computed based on the prescribed nodal velocity field. From this rigid body momentum, the translational and rotational velocities of the nodal points are computed and reset to the new values. These new values may or may not be the same as the values prescribed for the nodes that make up the rigid body. Sometimes this occurs in single precision due to numerical round-off. If a problem like this occurs, specify the velocity using the keyword *INITIAL_VELOCITY_RIGID_BODY.
5. **Mid-Side Nodes.** Mid-side nodes generated by *ELEMENT_SOLID_TET4-TO10 will not be initialized since the node numbers are not known a priori to the user. Instead use *INITIAL_VELOCITY_GENERATION if you intend to initialize the velocities of the mid-side nodes.

***INITIAL_VELOCITY_NODE**

Purpose: Define initial nodal point velocities for a node.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|----|----|----|-----|-----|-----|------|
| Variable | NID | VX | VY | VZ | VXR | VYR | VZR | ICID |
| Type | I | F | F | F | F | F | F | I |
| Default | none | 0. | 0. | 0. | 0. | 0. | 0. | 0 |

VARIABLE**DESCRIPTION**

| | |
|------|---|
| NID | Node ID |
| VX | Initial translational velocity in x -direction |
| VY | Initial translational velocity in y -direction |
| VZ | Initial translational velocity in z -direction |
| VXR | Initial rotational velocity about the x -axis |
| VYR | Initial rotational velocity about the y -axis |
| VZR | Initial rotational velocity about the z -axis |
| ICID | Local coordinate system ID. The specified velocities are in the local system if ICID is greater than zero. Furthermore, if ICID is greater than zero, *INCLUDE_TRANSFORM does not rotate the initial velocity values specified by VX, VY, ..., VZR. |

See Remarks on *INITIAL_VELOCITY card.

***INITIAL_VELOCITY_RIGID_BODY**

Purpose: Define the initial translational and rotational velocities at the center of gravity (c.g.) for a rigid body or a nodal rigid body. This input overrides all other velocity input for the rigid body and the nodes which define the rigid body.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|----|----|----|-----|-----|-----|------|
| Variable | PID | VX | VY | VZ | VXR | VYR | VZR | ICID |
| Type | I | F | F | F | F | F | F | I |
| Default | none | 0. | 0. | 0. | 0. | 0. | 0. | 0 |

VARIABLE**DESCRIPTION**

| | |
|------|--|
| PID | Part ID of the rigid body or the nodal rigid body. |
| VX | Initial translational velocity at the c.g. in global x -direction. |
| VY | Initial translational velocity at the c.g. in global y -direction. |
| VZ | Initial translational velocity at the c.g. in global z -direction. |
| VXR | Initial rotational velocity at the c.g. about the global x -axis. |
| VYR | Initial rotational velocity at the c.g. about the global y -axis. |
| VZR | Initial rotational velocity at the c.g. about the global z -axis. |
| ICID | Local coordinate system ID. The specified velocities are in the local system if ICID is greater than zero. Furthermore, if ICID is greater than zero, *INCLUDE_TRANSFORM does not transform the initial velocity values specified by VX, VY, ..., VZR. |

See Remarks 3 and 4 of the *INITIAL_VELOCITY input description.

*INITIAL_VELOCITY_GENERATION

Purpose: Define initial velocities for rotating and translating bodies.

NOTE: Rigid body velocities cannot be reinitialized after dynamic relaxation by setting PHASE = 1 since rigid body velocities are always restored to the values that existed prior to dynamic relaxation. Reinitialization of velocities after dynamic relaxation is only available for nodal points of deformable bodies; therefore, if rigid bodies are present in the part set ID, this input should be defined twice, once for PHASE = 0 and again for PHASE = 1.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|------|-------|----|----|----|-------|--------|
| Variable | ID | STYP | OMEGA | VX | VY | VZ | IVATN | ICID |
| Type | I | I | F | F | F | F | I | I |
| Default | {all} | ↓ | 0. | 0. | 0. | 0. | 0 | global |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|----|----|----|----|-------|--------|
| Variable | XC | YC | ZC | NX | NY | NZ | PHASE | IRIGID |
| Type | F | F | F | F | F | F | I | I |
| Default | 0. | 0. | 0. | 0. | 0. | 0. | 0 | 0 |

VARIABLE**DESCRIPTION**

ID

Part ID, part set ID, or node set ID. If zero, STYP is ignored, and all velocities are set. WARNING for if IVATN = 0: If a part ID of a rigid body is specified, only the nodes that belong to elements of the rigid body are initialized. Nodes defined under the keyword. *CONSTRAINED_EXTRA_NODES are not initialized. Set IVATN = 1 to initialize velocities of slave nodes and parts.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| STYP | Set type. See Remark 5 . EQ.1: part set ID, see *SET_PART, EQ.2: part ID, see *PART, EQ.3: node set ID, see *SET_NODE. |
| OMEGA | Angular velocity about the rotational axis. |
| VX | Initial translational velocity in x -direction (see ICID below). |
| VY | Initial translational velocity in y -direction (see ICID below). |
| VZ | Initial translational velocity in z -direction (see ICID below). |
| IVATN | Flag for setting the initial velocities of slave nodes and parts: EQ.0: slave parts are ignored. EQ.1: slave parts and slave nodes of the master parts will be assigned initial velocities like the master part. |
| ICID | Local coordinate system ID. If ICID = 0, the specified translational velocities (VX,VY,VZ) and the direction cosines of the rotation axis (NX,NY,NZ) are in the global system; otherwise they are in the local system specified by ICID. Therefore, if ICID is defined, *INCLUDE_TRANSFORM does not transform (VX,VY,VZ) and (NX,NY,NZ). |
| XC | Global x -coordinate on rotational axis. |
| YC | Global y -coordinate on rotational axis. |
| ZC | Global z -coordinate on rotational axis. |
| NX | x -direction cosine. If set to -999, NY and NZ are interpreted as the 1 st and 2 nd nodes defining the rotational axis, in which case the coordinates of node NY are used as XC, YC, ZC. If ICID is defined, the direction cosine, (NX,NY,NZ), is projected along coordinate system ICID to yield the direction cosines of the rotation axis only if NX \neq -999. |
| NY | y -direction cosine or the 1 st node of the rotational axis when NX = -999. |

| VARIABLE | DESCRIPTION |
|----------|---|
| NZ | z-direction cosine or the 2 nd node of the rotational axis when NX = -999. |
| PHASE | Flag specifying phase of the analysis the velocities apply to: EQ.0: Velocities are applied immediately, EQ.1: Velocities are applied after reaching the start time, STIME, which is after dynamic relaxation, if active, is completed. See the keyword: *INITIAL_VELOCITY_GENERATION_START_TIME. STIME defaults to zero. |
| IRIGID | Controls hierarchy of initial velocities set with *INITIAL_VELOCITY_GENERATION versus those set with *PART_INERTIA / *CONSTRAINED_NODAL_RIGID_BODY_INERTIA when the commands conflict. EQ.0: *PART_INERTIA / *CONSTRAINED_NODAL_RIGID_BODY_INERTIA controls initial velocities. EQ.1: *INITIAL_VELOCITY_GENERATION controls initial velocities. This option does not apply if STYP = 3. |

Remarks:

1. **Exclusions.** This generation input must not be used with *INITIAL_VELOCITY or *INITIAL_VELOCITY_NODE options.
2. **Order Dependence.** The velocities are initialized in the order the *INITIAL_VELOCITY_GENERATION input is defined. Later input via the *INITIAL_VELOCITY_GENERATION keyword may overwrite the velocities previously set.
3. **Consistency for Rigid Body Nodes.** Nodes which belong to rigid bodies must have motion consistent with the translational and rotational velocity of the rigid body. During initialization the rigid body translational and rotational rigid body momentum's are computed based on the prescribed nodal velocities. From this rigid body motion the velocities of the nodal points are computed and reset to the new values. These new values may or may not be the same as the values prescribed for the node.
4. **SPH.** SPH elements can be initialized using the STYP = 3 option only.
5. **Constrained Nodal Rigid Bodies.** Part IDs of *CONSTRAINED_NODAL_RIGID_BODYs that do not include the INERTIA option are not recognized by

the code in the case of STYP = 1 or 2. Use STYP = 3 (a node set ID) when initializing velocity of such nodal rigid bodies.

*INITIAL_VELOCITY_GENERATION_START_TIME

Purpose: Define a time to initialize velocities after time zero. Time zero starts after dynamic relaxation if used for initialization.

| | | | | | | | | |
|----------|-------|---|---|---|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | STIME | | | | | | | |
| Type | F | | | | | | | |
| Default | 0.0 | | | | | | | |

VARIABLE

DESCRIPTION

| | |
|-------|-------------|
| STIME | Start time. |
|-------|-------------|

Remarks:

- One Start Time.** Only one *INITIAL_VELOCITY_GENERATION_START_TIME can be specified. Multiple start times are not allowed.
- Using Start Time.** All *INITIAL_VELOCITY_GENERATION commands adhere to the start time provided the requirement is met that at least one of those commands has PHASE set to 1.
- Velocities of Other Nodes.** When *INITIAL_VELOCITY_GENERATION_START_TIME is active, nodes that are not part of the initial velocity generation definitions will be re-initialized with velocities as they were at $t = 0$.

***INITIAL_VOID_OPTION**

Available options include:

PART

SET

Purpose: Define initial voided part set IDs or part numbers. This command can be used only when ELFORM = 12 in *SECTION_SOLID. Void materials cannot be created during the calculation. Fluid elements which are evacuated, such as by a projectile moving through the fluid, during the calculation are approximated as fluid elements with very low densities. The constitutive properties of fluid materials used as voids must be identical to those of the materials which will fill the voided elements during the calculation. Mixing of two fluids with different properties is not permitted with this option.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|---|---|---|---|---|---|---|
| Variable | PSID/PID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

VARIABLE**DESCRIPTION**

PSID/PID

Part set ID or part ID, see also *SET_PART:

Remarks:

This void option and multiple materials per element, see *ALE_MULTI-MATERIAL_-GROUP are incompatible and cannot be used together in the same run.

*INITIAL_VOLUME_FRACTION_{OPTION}

Available option:

<BLANK>

NALEGP

Purpose: Define initial volume fractions of different materials in multi-material ALE elements. Without the NALEGP option, the keyword allows up to 7 ALE multi-material groups. The NALEGP option adds in an additional card immediately after the keyword to let users input the number of ALE multi-material groups to be read in for each element.

Card Summary:

Card 1a. This card is included if and only if there is no option. Repeat this card as many times as desired (one card for each element volume fraction to be defined). This input ends at the next keyword ("*") card.

| | | | | | | | |
|-----|-----|-----|-----|-----|-----|-----|-----|
| EID | VF1 | VF2 | VF3 | VF4 | VF5 | VF6 | VF7 |
|-----|-----|-----|-----|-----|-----|-----|-----|

Card 1b. This card is included if and only if the option is NALEGP. This card set (Card 1b, 1b.1, and 1b.2) is repeated as many times as desired (one set for each element volume fraction to be defined).

| | | | | | | | |
|--------|--|--|--|--|--|--|--|
| NALEGP | | | | | | | |
|--------|--|--|--|--|--|--|--|

Card 1b.1. This card is included if and only if the option is NALEGP.

| | | | | | | | |
|-----|-----|-----|-----|-----|-----|-----|-----|
| EID | VF1 | VF2 | VF3 | VF4 | VF5 | VF6 | VF7 |
|-----|-----|-----|-----|-----|-----|-----|-----|

Card 1b.2. This card is included if and only if the option is NALEGP and NALEGP > 7. Repeat this card in each set enough times to define NALEGP volume fractions.

VARIABLE**DESCRIPTION**

| | |
|-------|--|
| EID | Element ID. |
| VF1 | Volume fraction of multi-material group 1, AMMGID = 1. |
| VF2 | Volume fraction of multi-material group 2. Only needed in simulations with at least 3 material groups. Otherwise $VF2 = 1 - VF1$. |
| VF3 | Volume fraction of multi-material group 3, AMMGID = 3. |
| VF4 | Volume fraction of multi-material group 4, AMMGID = 4. |
| VF5 | Volume fraction of multi-material group 5, AMMGID = 5. |
| VF6 | Volume fraction of multi-material group 6, AMMGID = 6. |
| VF7 | Volume fraction of multi-material group 7, AMMGID = 7. |
| VF(N) | Volume fraction of multi-material group N, AMMGID = N. Define NALEGP volume fractions. |

***INITIAL_VOLUME_FRACTION_GEOMETRY**

Purpose: This is a volume-filling command for defining the volume fractions of various ALE multi-material groups (AMMG) that initially occupy several spatial regions in an ALE mesh. This applies only to ELFORMs 11 and 12 in *SECTION_SOLID and ALEFORM 11 in *SECTION_ALE2D. For ELFORM 12, AMMGID 2 is void. See [Remark 2](#).

Card Summary:

Card 1. This card is required.

Data Cards:

Background ALE Mesh Card. Defines the background ALE mesh set & an AMMGID that initially fills it.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---------|-------|--------|---|---|---|---|
| Variable | FMSID | FMIDTYP | BAMMG | NTRACE | | | | |
| Type | I | I | I | I | | | | |
| Default | none | 0 | none | 3 | | | | |

VARIABLE**DESCRIPTION**

FMSID

A background ALE (fluid) mesh SID to be initialized or filled with various AMMG's. This set ID refers to one or more ALE parts.

FMIDTYP

ALE mesh set ID type:

EQ.0: FMSID is an ALE part set ID (PSID).

EQ.1: FMSID is an ALE part ID (PID).

BAMMG

The background fluid group ID or ALE Multi-Material group ID (AMMGID) that initially fills all ALE mesh region defined by FMSID.

NTRACE

Number of sampling points for volume filling detection. Typically, NTRACE ranges from 3 to maybe 10 (or more). The higher it is, the finer the ALE element is divided so that small gaps between 2 Lagrangian shells may be filled in. See [Remark 4](#).

Container Card. Defines the container type and the AMMGID that fills the region defined by the container type.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|---------|-------|----|----|----|---|---|
| Variable | CNTTYP | FILLOPT | FAMMG | VX | VY | VZ | | |
| Type | I | I | I | F | F | F | | |
| Default | none | 0 | none | 0 | 0 | 0 | | |

VARIABLE**DESCRIPTION****CNTTYP**

A “container” defines a Lagrangian surface boundary of a spatial region, inside (or outside) of which, an AMMG would fill up. CNTTYP defines the container geometry type of this surface boundary (or shell structure).

EQ.1: The container geometry is defined by a part ID (PID) or a part set ID (PSID), where the parts should be defined by shell elements (see *PART or *SET_PART).

EQ.2: The container geometry is defined by a segment set (SGSID).

EQ.3: The container geometry is defined by a plane: a point and a normal vector.

EQ.4: The container geometry is defined by a conical surface: 2 end points and 2 corresponding radii (in 2D see [Remark 6](#)).

EQ.5: The container geometry is defined by a cuboid or rectangular box: 2 opposing end points, minimum to maximum coordinates.

EQ.6: The container geometry is defined by a sphere: 1 center point, and a radius.

FILLOPT

A flag to indicate which side of the container surface the AMMG is supposed to fill. The “head” side of a container surface/segment is defined as the side pointed to by the heads of the normal vectors of the segments (“tail” side refers to opposite direction to “head”). See [Remark 5](#).

EQ.0: The “head” side of the geometry defined above will be filled with fluid (default).

| VARIABLE | DESCRIPTION |
|----------|--|
| | EQ.1: The “tail” side of the geometry defined above will be filled with fluid. |
| FAMMG | This defines the fluid group ID or ALE Multi-Material group ID (AMMGID) which will fill up the interior (or exterior) of the space defined by the “container”. <i>The order of AMMGIDs is determined by the order in which they are listed under *ALE_MULTI-MATERIAL_GROUP card.</i> For example, the first data card under the *ALE_MULTI-MATERIAL_GROUP keyword defines the multi-material group with ID (AMMGID) 1, the second data card defined AMMGID = 2, and so on. LT.0: FAMMG is a *SET_MULTI-MATERIAL_GROUP_LIST ID listing pairs of group IDs. For each pair, the 2 nd group replaces the first one in the “container”. |
| VX | Initial velocity in the global <i>x</i> -direction for this AMMGID. |
| VY | Initial velocity in the global <i>y</i> -direction for this AMMGID. |
| VZ | Initial velocity in the global <i>z</i> -direction for this AMMGID. |

Part/Part Set Container Card. Additional card for CNTTYP = 1.

| Card 3a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|----------|--------|---|---|---|---|
| Variable | SID | STYPE | NORMDIR | XOFFST | | | | |
| Type | I | I | I | F | | | | |
| Default | none | 0 | 0 | 0.0 | | | | |
| Remark | | | obsolete | | | | | |

| VARIABLE | DESCRIPTION |
|----------|---|
| SID | A set ID pointing to a part ID (PID) or part set ID (PSID) of the Lagrangian shell element structure defining the “container” geometry to be filled (see *PART or *SET_PART). |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| SSTYPE | Set ID type: EQ.0: Container SID is a Lagrangian part set ID (PSID). EQ.1: Container SID is a Lagrangian part ID (PID). |
| NORMDIR | Obsolete (see Remark 5). |
| XOFFST | Absolute length unit for offsetting the fluid interface from the nominal fluid interface LS-DYNA would otherwise define by default. This field only applies to GEOTYP = 1 and GEOTYP = 2 (see *CONTACT_ENTITY). This is applicable to cases in which high pressure fluid is contained within a container. The offset allows LS-DYNA time to prevent leakage. In general, this may be set to roughly 5-10% of the ALE elm width. It may be important only for when ILEAK is turned ON to give the code time to "catch" the leakage (see *CONSTRAINED_LAGRANGE_IN_SOLID). If ILEAK is not ON, this may not be necessary. |

Segment Set Container Card. Additional card for CNTTYP = 2.

| Card 3b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|----------|--------|---|---|---|---|---|
| Variable | SGSID | NORMDIR | XOFFST | | | | | |
| Type | I | I | F | | | | | |
| Default | none | 0 | 0.0 | | | | | |
| Remark | | obsolete | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| SGSID | Segment Set ID defining the "container", see *SET_SEGMENT. |
| NORMDIR | Obsolete (see Remark 5). |

| VARIABLE | DESCRIPTION |
|----------|---|
| XOFFST | Absolute length unit for offsetting the fluid interface from the nominal fluid interface LSDYNA would otherwise define by default. This field only applies to GEOTYP = 1 and GEOTYP = 2 (see *CONTACT_ENTITY). This is applicable to cases in which high pressure fluid is contained within a container. The offset allows LS-DYNA time to prevent leakage. In general, this may be set to roughly 5-10% of the ALE element width. It may be important only for when ILEAK is turned ON to give the code time to "catch" the leakage (see *CONSTRAINED_LAGRANGE_IN_SOLID). If ILEAK is not ON, this may not be necessary. |

Plane Card. Additional card for CNTTYP = 3.

| Card 3c | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|---|---|
| Variable | X0 | Y0 | Z0 | XCOS | YCOS | ZCOS | | |
| Type | F | F | F | F | F | F | | |
| Default | none | none | none | none | none | none | | |

| VARIABLE | DESCRIPTION |
|------------------|--|
| X0, Y0, Z0 | x , y and z coordinate of a spatial point on the plane. |
| XCOS, YCOS, ZCOS | x , y and z direction cosines of the plane normal vector. The filling will occur on the side pointed to by the plane normal vector (or "head" side). |

Cylinder/Cone Container Card. Additional Card for CNTTYP = 4 (see [Remark 6](#) for 2D).

| Card 3d | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | X0 | Y0 | Z0 | X1 | Y1 | Z1 | R1 | R2 |
| Type | F | F | F | F | F | F | F | F |
| Default | none |

INITIAL**INITIAL_VOLUME_FRACTION_GEOMETRY**

| VARIABLE | DESCRIPTION |
|-----------------|--|
| X0, Y0, Z0 | x, y and z coordinate of the center of the 1 st base of the cone. |
| X1, Y1, Z1 | x, y and z coordinate of the center of the 2 nd base of the cone. |
| R1 | Radius of the 1 st base of the cone |
| R2 | Radius of the 2 nd base of the cone |

Rectangular Box Container Card. Additional Card for CNTTYP = 5.

| Card 3e | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|-------|---|
| Variable | X0 | Y0 | Z0 | X1 | Y1 | Z1 | LCSID | |
| Type | F | F | F | F | F | F | I | |
| Default | none | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| X0, Y0, Z0 | Minimum x, y and z coordinates of the box. |
| X1, Y1, Z1 | Maximum x, y and z coordinates of the box. |
| LCSID | Local coordinate system ID, if defined, the box is aligned with the local coordinate system instead of global coordinate system. Please see *DEFINE_COORDINATE_for details. |

Sphere Container Card. Additional card for CNTTYP = 6.

| Card b6 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|---|---|---|---|
| Variable | X0 | Y0 | Z0 | R0 | | | | |
| Type | F | F | F | F | | | | |
| Default | none | none | none | none | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| X0, Y0, Z0 | x, y and z coordinate of the center of the sphere. |

| VARIABLE | DESCRIPTION |
|----------|----------------------|
| R0 | Radius of the sphere |

Remarks:

1. **Structure of Data Cards.** After Card 1 which defines the basic mesh filled by a certain fluid group (AMMGID), each “filling action” will require 2 additional lines of input: Cards 2 and 3 α , where α depends on the CNTTYP value. At the minimum there will be 3 cards required for this command (1, 2, and 3 α) for 1 “filling action”.

There can be one or more “filling actions” prescribed for each instance of this command. The “filling actions” take place in the prescribed order and the effects are cumulative. Later “filling actions” will over-write the previous ones. Therefore, any complex filling logic will require some planning. For example, the following card sequence with 2 “filling actions” is allowable:

```
*INITIAL_VOLUME_FRACTION_GEOMETRY
[Card 1]
[Card 2, CNTTYP = 1]
[Card 3a]
[Card 2, CNTTYP = 3]
[Card 3c]
```

This sequence of cards prescribes a background ALE mesh with 2 “filling actions” to be executed. The 1st is a filling of a CNTTYP = 1 and the 2nd of CNTTYP = 3.

2. **Group IDs for ELFORM 12.** If ELFORM = 12, the single-material-and-void element formulation, is used in *SECTION_SOLID, then the non-void material defaults to AMMG = 1 and the void to AMMG = 2. These multi-material groups are implied even though no *ALE_MULTI-MATERIAL_GROUP card is required.
3. **Using Shells to Divide Space.** A simple ALE background mesh (for example, a cuboid mesh) can be constructed enveloping some Lagrangian shell structure (or container). The ALE region inside this Lagrangian shell container may be filled with one multi-material group (AMMG1), and the outside region with another (AMMG2). This approach simplifies the mesh generation requirements for ALE material parts with complex geometries.
4. **NTRACE.** The default number of sampling points is NTRACE = 3 in which case the total number is

$$(2 \times \text{NTRACE} + 1)^3 = 7^3$$

This means an ALE element is subdivided into $7 \times 7 \times 7$ regions. Each is to be filled in with the appropriate AMMG. An example of this application would be the filling of initial gas between multiple layers of Lagrangian airbag shell elements sharing the same ALE element.

5. **Interior/Exterior Fill Setting.** To set which side of a container is to be filled: (1) define the shell (or segment) container with inward normal vectors; then (2) set the FILLOPT field on "Card 2" to 0, corresponding to the head of the normal, for the interior, and to 1, corresponding to the tail of the normal, for the exterior.
6. **Two Dimensional Geometry.** If the ALE model is 2D (*SECTION_ALE2D instead of *SECTION_SOLID), CNTTYP = 4 defines a quadrilateral. In this case the fields which, in the 3D case define a cone, are interpreted as the corner coordinates of a clockwise defined (inward normal) quadrilateral having the vertices: (X1, Y1), (X2, Y2), (X3, Y3), and (X4, Y4). The CNTTYPE = 4 input fields X0, Y0, Z0, X1, Y1, Z1, R1, and R2 becomes X1, Y1, X2, Y2, X3, Y3, X4, and Y4 respectively. CNTTYP = 6 should be used to fill a circle.

Example:

Consider a simple ALE model with ALE parts H1-H5 (5 AMMGs possible) and 1 Lagrangian shell (container) part S6. Only parts H1 and S6 initially have their meshes defined. We will perform 4 "filling actions". The volume filling results after each step will be shown below to clarify the concept used. The input for the volume filling looks like this.

```

$...|...1...|...2...|...3...|...4...|...5...|...6...|...7...|...8
$ H1 = AMMG 1 = fluid 1 initially occupying whole ALE mesh= background mesh
$ H5 = AMMG 5 = fluid 5 fills below a plane = filling action 1 = CNTTYP=3

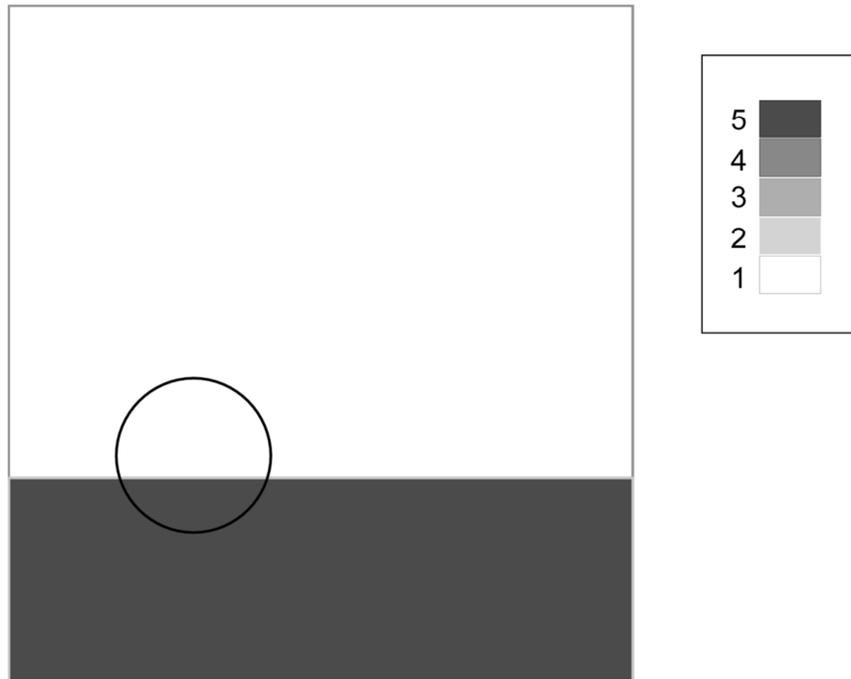

Figure 24-4. Before the 1st “filling action” the whole ALE mesh of part H1 is filled with AMMG 1 (white). After the 1st “filling action”, AMMG 5 fills below the specified plane.

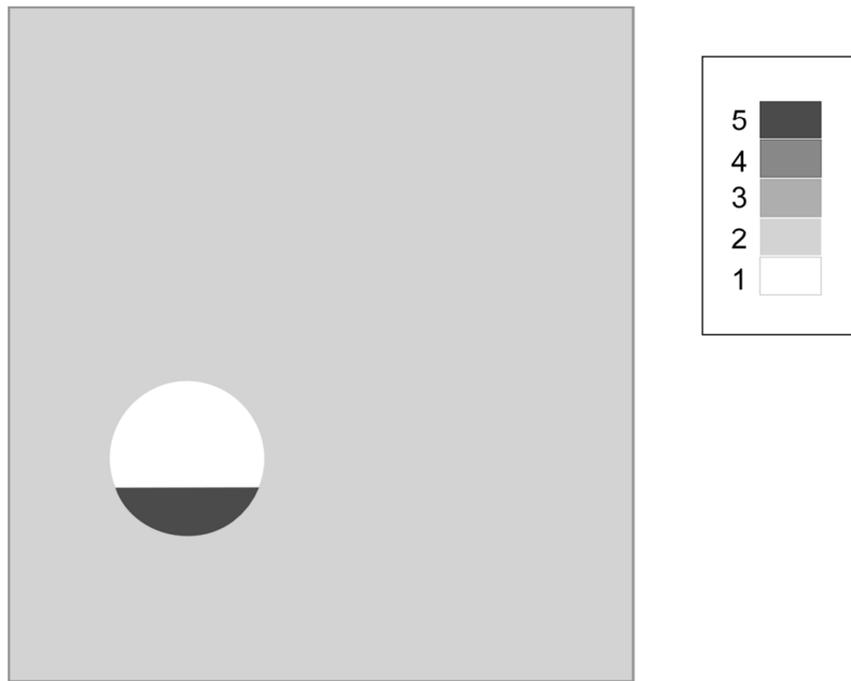

Figure 24-5. After the 1st and 2nd “filling actions”, outside the shell (S6) is filled with AMMG 2.

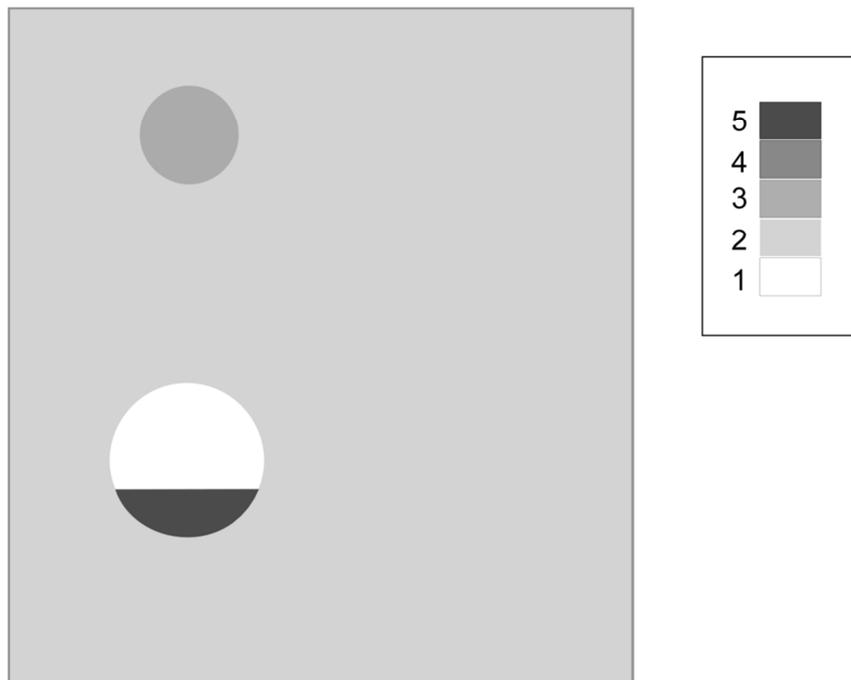

Figure 24-6. After the 1st, 2nd and 3rd “filling actions”, it fills in the analytical sphere with AMMG 3.

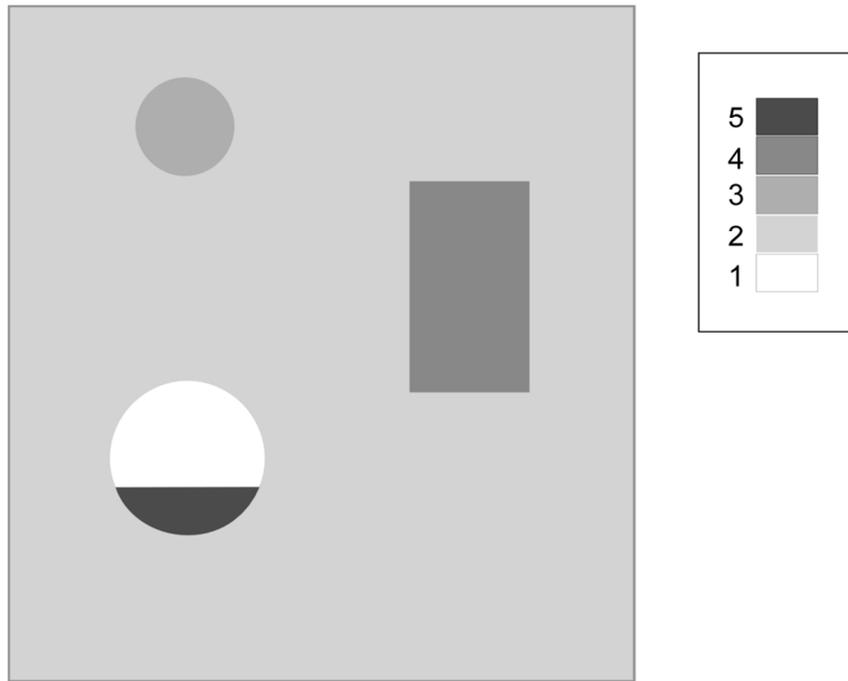

Figure 24-7. After the 1st, 2nd, 3rd and 4th “filling actions”, the analytical box is filled with AMMG 4.

***INTEGRATION**

In this section the user defined integration rules for beam and shell elements are specified. IRID refers to integration rule identification number on *SECTION_BEAM and *SECTION_SHELL cards respectively. Quadrature rules in the *SECTION_SHELL and *SECTION_BEAM cards need to be specified as a negative number. The absolute value of the negative number refers to user defined integration rule number. Positive rule numbers refer to the built in quadrature rules within LS-DYNA. The keyword cards in this section are:

*INTEGRATION_BEAM

*INTEGRATION_SHELL

*INTEGRATION

*INTEGRATION_BEAM

*INTEGRATION_BEAM

Purpose: To support user defined through the thickness integration rules for the beam element.

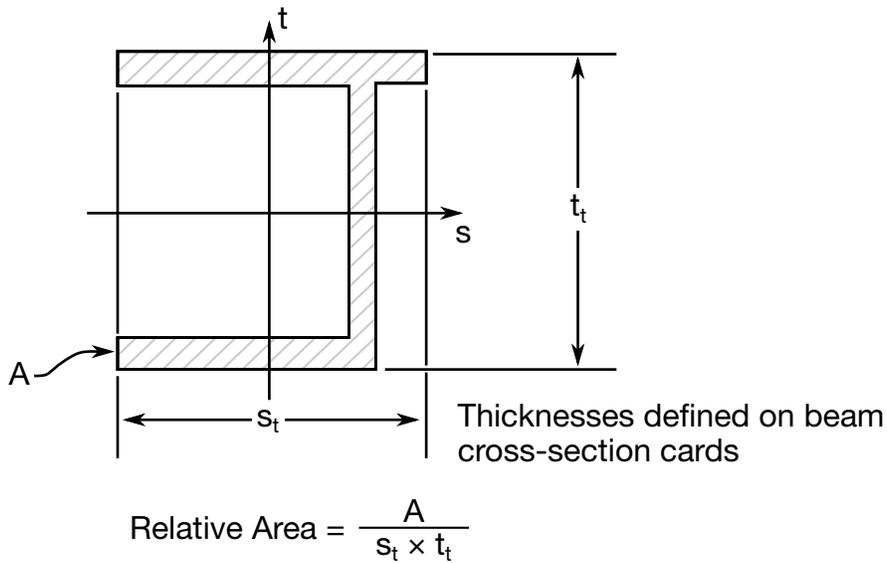

Figure 25-1. Definition of relative area for user defined integration rule.

| VARIABLE | DESCRIPTION |
|----------|---|
| IRID | Integration rule ID. IRID refers to IRID on *SECTION_BEAM card. |
| NIP | Number of integration points; see also ICST. |
| RA | Relative area of cross section, that is, the actual cross-sectional area divided by the area defined by the product of the specified thickness in the <i>s</i> -direction and the thickness in the <i>t</i> -direction. See also ICST below and Figure 25-1 . |
| ICST | Standard cross section type. If this type is nonzero, then NIP and the relative area above should be input as zero. See shapes in Figures 25-3 through 25-24 . |
| | EQ.01: I-Shape |
| | EQ.02: Channel |
| | EQ.03: L-shape |
| | EQ.04: T-shape |
| | EQ.05: Tubular box |
| | EQ.06: Z-Shape |
| | EQ.07: Trapezoidal |
| | EQ.08: Circular |
| | EQ.12: Cross |
| | EQ.13: H-Shape |
| | EQ.14: T-Shape 2 |
| | EQ.15: I-Shape 3 |
| | EQ.16: Channel 2 |
| | EQ.17: Channel 3 |
| | EQ.18: T-Shape 3 |
| | EQ.19: Box-Shape 2 |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | EQ.09: Tubular EQ.20: Hexagon EQ.10: I-Shape 2 EQ.21: Hat-Shape EQ.11: Solid Box EQ.22: Hat-Shape 2 |
| K | Integration refinement parameter, k , for standard cross section types. Select an integer ≥ 0 . See Figures 25-3 through 25-24 . |
| D1-D6 | Cross-section dimensions. See Figures 25-3 through 25-24 . |
| SREF | s_{ref} , location of reference surface normal to s , for the Hughes-Liu beam only. This option is only useful if the beam is connected to a shell or another beam on its outer surface. Overrides NSLOC in *SECTION_BEAM, even if SREF = 0. |
| TREF | t_{ref} , location of reference surface normal to t , for the Hughes-Liu beam only. This option is only useful if the beam is connected to a shell or another beam on its outer surface. Overrides NTLOC in *SECTION_BEAM, even if TREF = 0. |
| S | Normalized s -coordinate of integration point, $-1 \leq s \leq 1$. |
| T | Normalized t -coordinate of integration point, $-1 \leq t \leq 1$. |
| WF | Weighting factor, A_{ri} , that is the area associated with the integration point divided by actual cross sectional area $A_{ri} = A_i/A$; see Figure 25-2 . |
| PID | Optional PID, used to identify material properties for this integration point. If zero, the "master" PID (referenced on *ELEMENT) will be used. This feature is available as of release 3 of version 971. |

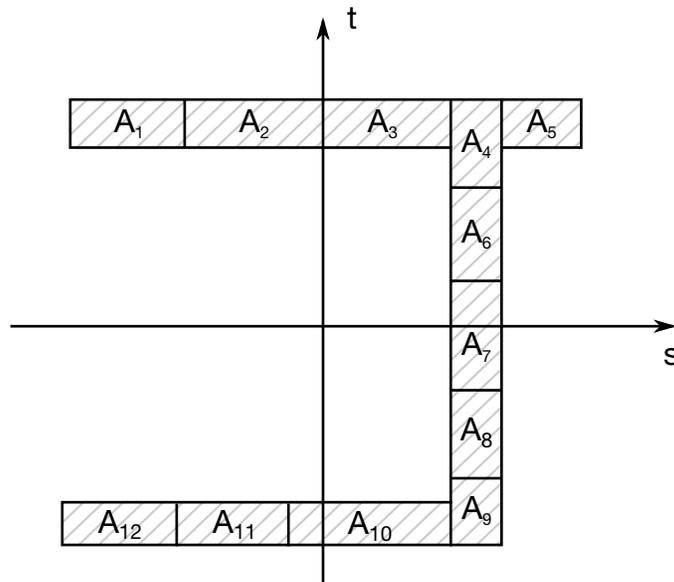

Figure 25-2. Definition of integration points for user defined integration rule.

Remarks:

The input for standard beam section types is defined below. In the following figures the dimensions are shown on the left and the location of the integration points are shown on the right. If a quantity is not defined in the sketch, then it should be set to zero in the input. The input quantities include:

- D1 - D6 = Dimensions of section
- k = Integration refinement parameter (an integer ≥ 0)
- s_{ref} = location of reference surface normal to s , Hughes-Liu beam only
- t_{ref} = location of reference surface normal to t , Hughes-Liu beam only

***INTEGRATION_SHELL**

Purpose: Define user defined through the thickness integration rules for the shell element. This option applies to three dimensional shell elements with three or four nodes (*ELEMENT_SHELL types 1-11 and 16) and to the eight node thick shell (*ELEMENT_TSHELL). See *PART_COMPOSITE for a simpler alternative to *PART + *SECTION_SHELL + *INTEGRATION_SHELL.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|------|---------|---|---|---|---|
| Variable | IRID | NIP | ESOP | FAILOPT | | | | |
| Type | I | I | I | I | | | | |

Define NIP cards below if ESOP = 0.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---|----|-----|---|---|---|---|---|
| Variable | S | WF | PID | | | | | |
| Type | F | F | I | | | | | |

VARIABLE**DESCRIPTION**

| | |
|---------|--|
| IRID | Integration rule ID (IRID refers to IRID on *SECTION_SHELL card). |
| NIP | Number of integration points |
| ESOP | Equal spacing of integration points option: EQ.0: integration points are defined below, EQ.1: integration points are equally spaced through thickness such that the shell is subdivided into NIP layers of equal thickness. |
| FAILOPT | Treatment of failure when mixing different constitutive types, which do and do not include failure models, through the shell thickness. For example, consider the case where a linear viscoelastic material model, which does not have a failure option, is mixed with a composite model, which does have a failure option. Note: If the failure option includes failure based on the time step size of the element, element deletion will occur |

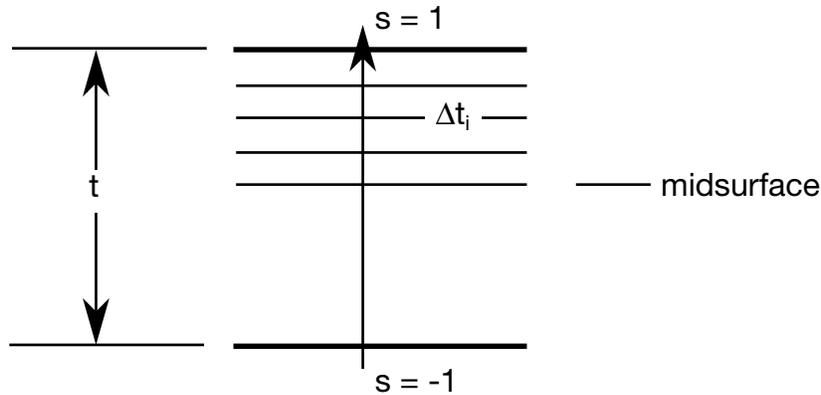

Figure 25-25. In the user defined shell integration rule the ordering of the integration points is arbitrary.

| VARIABLE | DESCRIPTION |
|----------|--|
| | regardless of the value of FAILOPT. |
| | EQ.0: Element is deleted when the layers which include failure, fail. |
| | EQ.1: Element failure cannot occur since some layers do not have a failure option. |
| S | Coordinate of integration point in range -1 to 1. |
| WF | Weighting factor. This is typically the thickness associated with the integration point divided by actual shell thickness, that is, the weighting factor for the i^{th} integration point = $\Delta t_i / t$ as seen in Figure 25-25 . |
| PID | Optional part ID if different from the PID specified on the element card. The average mass density for the shell element is based on a weighted average of the density of each layer that is used through the thickness. When modifying the constitutive constants through the thickness, it is often necessary to defined unique part IDs without elements that are referenced only by the user integration rule. These additional part IDs only provide a density and constitutive constants with local material axes (if used) and orientation angles taken from the PID referenced on the element card. In defining a PID for an integration point, it is okay to reference a solid element PID. The material type through the thickness can vary. |

***INTERFACE**

Interface definitions may be used to define surfaces, nodal lines, and nodal points for which the displacement and velocity time histories are saved at some user specified frequency. This data may then be used in subsequent analyses as an interface ID in the **INTERFACE_LINKING_DISCRETE_NODE* as master nodes, in **INTERFACE_LINKING_SEGMENT* as master segments and in **INTERFACE_LINKING_EDGE* as the master edge for a series of nodes. This capability is especially useful for studying the detailed response of a small member in a large structure.

For the first analysis, the member of interest need only be discretized sufficiently that the displacements and velocities on its boundaries are reasonably accurate. After the first analysis is completed, the member can be finely discretized in the region bounded by the interfaces. Finally, the second analysis is performed to obtain highly detailed information in the local region of interest. When beginning the first analysis, specify a name for the interface segment file using the *Z =* parameter on the LS-DYNA execution line. When starting the second analysis, the name of the interface segment file created in the first run should be specified using the *L =* parameter on the LS-DYNA command line. Following the above procedure, multiple levels of sub-modeling are easily accommodated. The interface file may contain a multitude of interface definitions so that a single run of a full model can provide enough interface data for many component analyses. The interface feature represents a powerful extension of LS-DYNA's analysis capabilities. The keyword cards for this purpose are:

- *INTERFACE_COMPENSATION_3D*
- *INTERFACE_COMPONENT_FILE*
- *INTERFACE_COMPONENT_OPTION*
- *INTERFACE_LINKING_DISCRETE_NODE_OPTION*
- *INTERFACE_LINKING_EDGE*
- *INTERFACE_LINKING_FILE*
- *INTERFACE_LINKING_NODE*
- *INTERFACE_LINKING_SEGMENT*
- *INTERFACE_SPRINGBACK_OPTION1_OPTION2*

Interface definitions may also be employed to define soil-structure interfaces in earthquake analysis involving non-linear soil-structure interaction where the structure may be non-linear, but the soil outside the soil-structure interface is assumed to be

***INTERFACE**

linear. Free-field earthquake ground motions are required only at the soil-structure interface for such analysis. The keyword cards for this purpose are:

*INTERFACE_SSI

*INTERFACE_SSI_AUX

*INTERFACE_SSI_AUX_EMBEDDED

*INTERFACE_SSI_STATIC

***INTERFACE_BLANKSIZE_OPTION**

Available options include:

DEVELOPMENT

INITIAL_TRIM

INITIAL_ADAPTIVE

SCALE_FACTOR

SYMMETRIC_PLANE

Purpose: This keyword causes LS-DYNA to run a blank-size development calculation instead of a finite element calculation. The input for this feature consists of (1) the result of a completed metal forming simulation, (2) the corresponding initial blank, and (3) the desired result from the simulation in the form of a boundary curve or full mesh. From these inputs the *INTERFACE_BLANKSIZE method adjusts the initial blank so that the resulting formed piece more closely matches the target. The blank's starting geometry may be systematically improved by iterating. A GUI for using this available in LS-PrePost as of version 4.2 under *APPLICATION* → *Metal Forming* → *Blank Size/Trim line*.

| |
|--|
| <p>NOTE: When this card is present, LS-DYNA <i>does not</i> proceed to the finite element simulation.</p> |
|--|

This keyword requires one or all three keyword options in the input deck, each corresponding to a different kind of forming operation:

1. **DEVELOPMENT.** This option takes as its target either a full mesh or a minimum boundary. It adjusts the blank so that the product more closely approximates the target. The computed blank-boundary is written to a file called *trimcurves.ibo*, which contains a *DEFINE_CURVE_TRIM_3D keyword.
2. **INITIAL_TRIM.** This option adjusts the blank so that trimming and mesh-refinement are mapped back onto the initial blank.
3. **INITIAL_ADAPTIVE.** This option reads in (1) the input mesh for a flanging simulation as well as (2) the adapted mesh calculated during flanging simulation. It maps the refinement back to the initial blank.

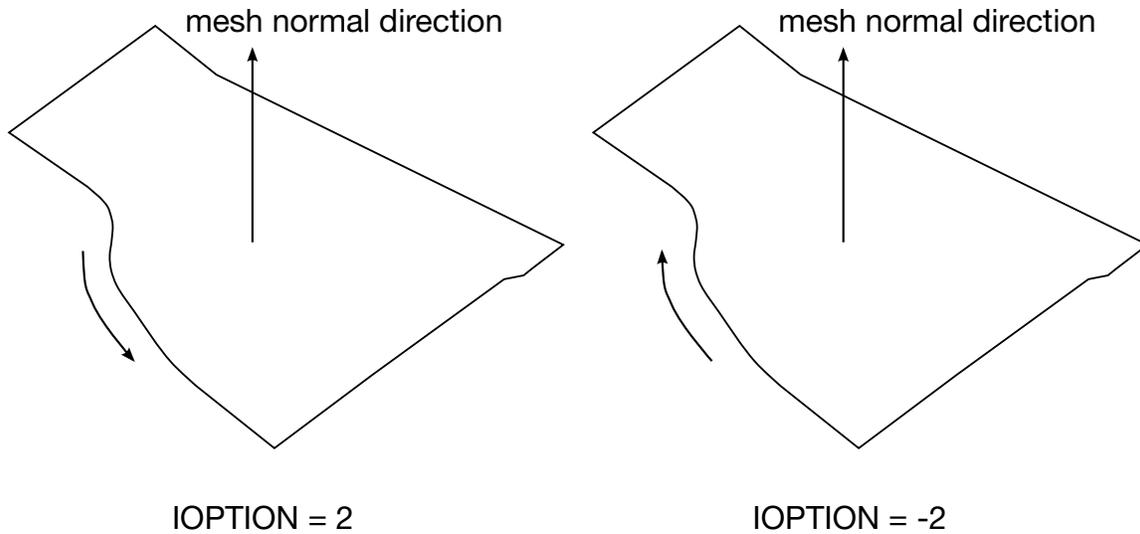

Figure 26-2. Differences between IOPTION 2 and -2.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| IOPTION | <p>Target curve definition input type:</p> <p>EQ.1: (entire) blank mesh in keyword format.</p> <p>EQ.2: consecutive position coordinates of blank boundary loop curve in XYZ format, defined by *DEFINE_TARGET_BOUNDARY. The blank mesh's normal vector and the closed boundary curve are consistently oriented according to the right-hand rule, see Figure 26-2. Note the target boundary curves must have enough points for a successful prediction of the initial blank size.</p> <p>EQ.-2: consecutive position coordinates of blank boundary loop curve in XYZ format, defined by *DEFINE_TARGET_BOUNDARY. The blank mesh's normal vector and the closed boundary curve are consistently oriented according to the left-hand rule, see Figure 26-2. Note the target boundary curves must have enough points for a successful prediction of the initial blank size.</p> <div data-bbox="641 1701 1274 1917" style="border: 1px solid black; padding: 5px;"><p>NOTE: Starting with Revision 100589, curve direction is desensitized, meaning <i>both</i> IOPTION = 2 and IOPTION = -2 will give the same results.</p></div> |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | In LS-PrePost 4.0, menu option <i>GeoTol</i> → <i>ID Measure</i> can be used to show the flow direction of a boundary curve. <i>Curve</i> → <i>Rever(se)</i> can be used to reverse the curve direction. |
| IADAPT | Adaptive mesh control flag. If IADAPT = 1, the number of elements in the meshes initial (FILENAME3) and simulated blank (FILENAME2) can be different, so it is not necessary to use the sheet blank from the file <i>adapt.msh</i> (created by setting IOFLAG = 1 in *CONTROL_ADAPTIVE) for the initial blank mesh. |
| MAXSIZE | The maximum change in initial blank size in each iteration. It is used to limit the blank size change in each iteration during mapping to avoid convergence problems when the initial blank is curved. |
| REF | Flag to indicate trim curve projection to a reference surface (mesh); see Figure 26-1 : EQ.0: no projection. EQ.1: the trim curves will be projected to the reference surface. In addition, the mesh file for the reference surface is given in FILENAME4. |
| SPACE | Point spacing distance on the reference surface for the projected curve; see Figure 26-1 . If the gap between two neighboring points in the modified trimming curve is larger than this value, extra nodes will be added in the final blank and projected to the reference surface. A smaller value should be used for large reference surface curvature. |
| MAXGAP | When REF is set to 1, the nodes from the final blank will be projected to the reference surface. However, if the distance between the nodes and the surface is larger than MAXGAP, the nodes will not be projected. |
| ORIENT | A flag to control iterative optimization efficiency or to include a reference surface file for the final formed blank. EQ.1: activates a new algorithm to potentially reduce the number of iterations during the iterative blank size optimization loop. This activation should be used in conjunction with the keyword option SCALE_FACTOR (0.75~0.9). |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | EQ.2: to include a reference surface FILENAME13 (in keyword mesh format) for the simulated (formed) blank. This is useful when the formed blank is smaller than intended and extended surfaces are not flat. See Example II and Figure 26-1 . |
| FILENAME1 | Target input file name. When a blank mesh is used (IOP-TION = 1), the keyword file must contain *NODE and *ELEMENT_SHELL keywords. When using the blank boundary curve for target (IOPTION = 2), the file must consist of *DEFINE_TARGET_BOUNDARY. See the Target Boundaries (and IGES) in the Remarks section. |
| FILENAME2 | Simulated (formed or flanged) sheet blank mesh in keyword format. This mesh can be obtained from the final state of any downstream process simulation. |
| FILENAME3 | Initial sheet blank mesh in keyword format. This can be the first state mesh from any process simulation prior to FILENAME2 simulation. Set IADAPT = 1 if adaptive refinement is used in any simulation. |
| FILENAME4 | Reference surface onto which adjustments to the blank's trim curves in its initial state are projected (ref3.k in Figure 26-1). This surface is typically a curved extension of the initial blank and must be defined as a mesh in keyword format. This file name must be defined when REF is set to 1. Also see extended reference surface for the final state (formed state), FILENAME13. |
| FILENAME13 | Reference surface onto which adjustments to the blank's trim curves in its final state are projected (ref4.k in Figure 26-1). This surface is typically a curved extension of the formed blank and must be defined as mesh in keyword format. This file name must be defined when ORIENT is set to 2. |

Card Set for *INTERFACE_BLANKSIZE_INITIAL_TRIM.

Initial Flat blank. FILENAME5 should specify the mesh of a blank that has been refined during a subsequent forming operation. FILENAME5 is usually set to the adapt.msh output. See "OP10 Initial Adapted blank mesh" in Figure 26-3.

| | | | | | | | | |
|----------|-----------|---|---|---|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | FILENAME5 | | | | | | | |
| Type | A80 | | | | | | | |

Formed blank. FILENAME6 specifies a dynain file from a forming simulation. See "OP10 Final blank" in Figure 26-3.

| | | | | | | | | |
|----------|-----------|---|---|---|---|---|---|---|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | FILENAME6 | | | | | | | |
| Type | A80 | | | | | | | |

Trimmed Formed blank. A dynain file from a trimming simulation that started with the state given in FILENAME6. See "OP20 Final blank" in Figure 26-3.

| | | | | | | | | |
|----------|-----------|---|---|---|---|---|---|---|
| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | FILENAME7 | | | | | | | |
| Type | A80 | | | | | | | |

Trimmed Flat blank (output). This field specifies the name for the file to which the trimmed flat blank is written. See "OP20 Flat New" in Figure 26-3.

| | | | | | | | | |
|----------|-----------|---|---|---|---|---|---|---|
| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | FILENAME8 | | | | | | | |
| Type | A80 | | | | | | | |

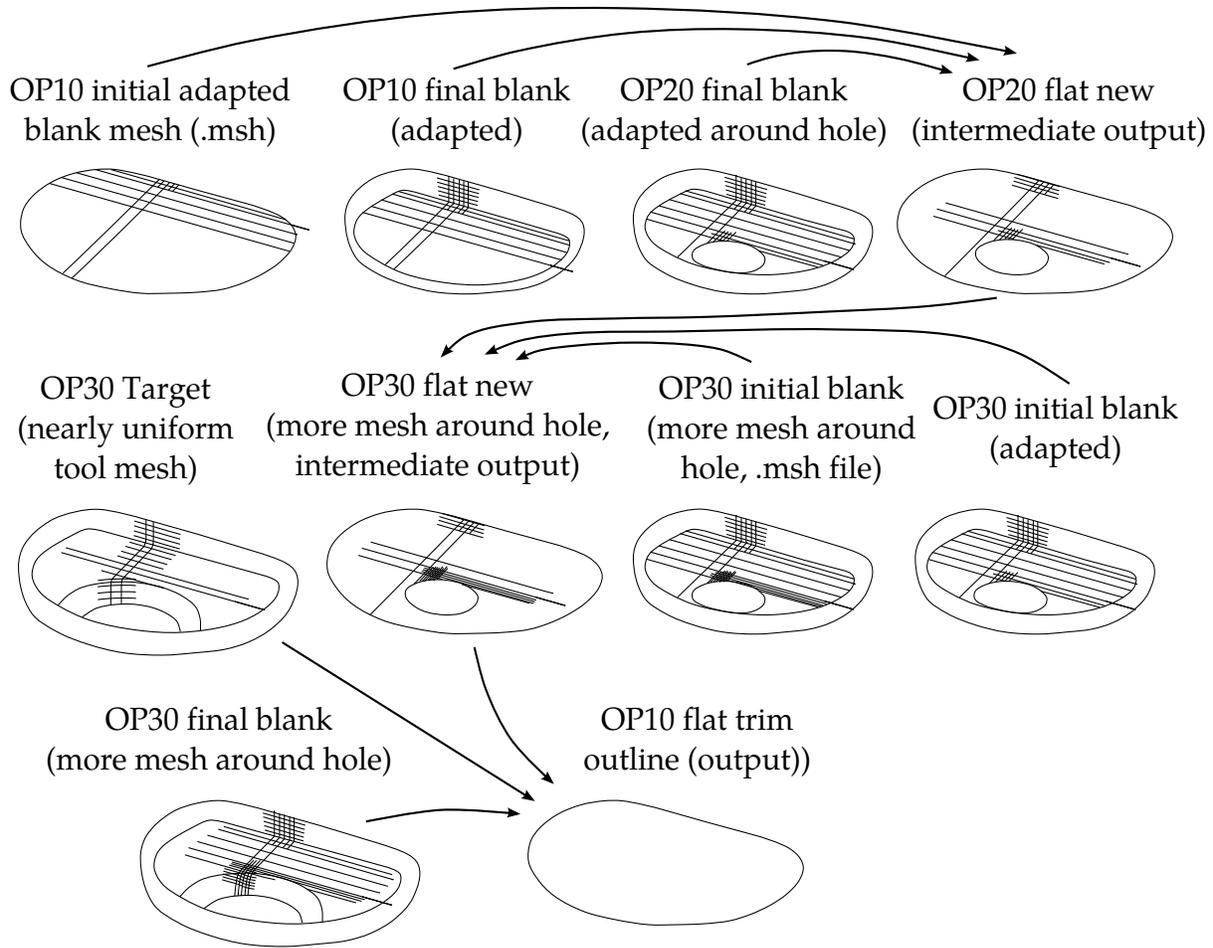

Figure 26-3. Inputs and outputs (Courtesy of Metal Forming Analysis Corp.). For exposition of labels OP10, OP20, and OP30 see [Figure 26-4](#).

| VARIABLE | DESCRIPTION |
|-----------------|--|
| FILENAME5 | Initial blank in its flat configuration <i>with</i> adapted mesh in keyword format. FILENAME5 usually points to an adapt.msh file. For example see OP10 in Figures 26-4, 26-22 and 26-3 , in which FILENAME5 is the adapt.msh from a draw-forming calculation. |
| FILENAME6 | Final formed blank in keyword format. This is usually the dynain file corresponding to the adapt.msh file mentioned above for FILENAME5; see Figures 26-4, 26-22 and 26-3 . |
| FILENAME7 | A trimmed blank in keyword format. This file should be derived from FILENAME6 as the dynain file from a trimming simulation. See OP20 in Figures 26-4, 26-22 and 26-3 . |

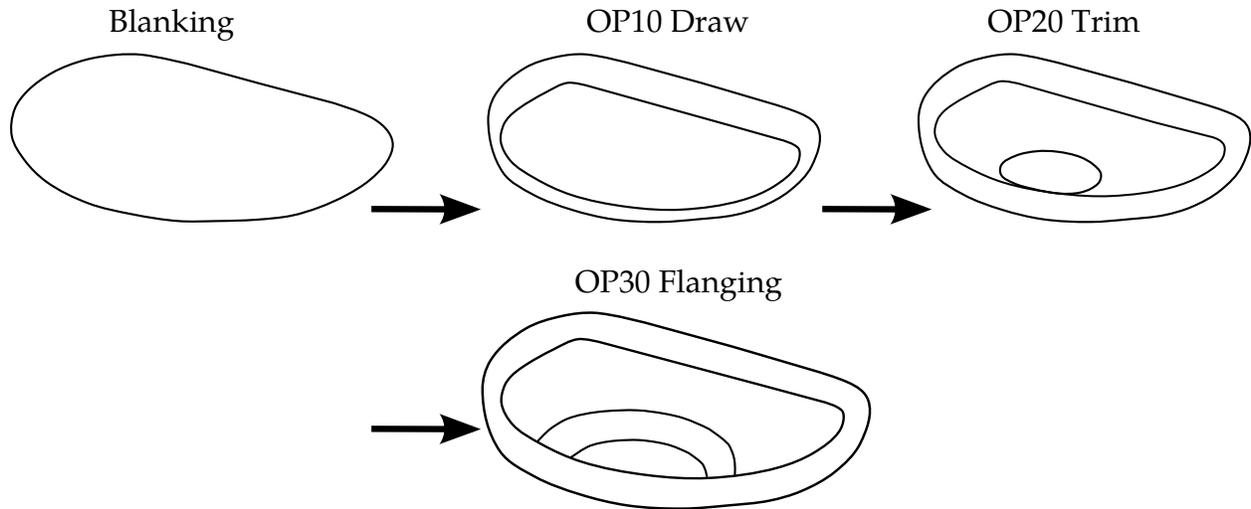

Figure 26-4. A stamping process consists of draw, trim and flanging (*Courtesy of Metal Forming Analysis Corporation*). The labels OP10, OP20, and OP30 are used *extensively* in the ensuing discussion.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| FILENAME8 | This field specifies the name for the file in which the trimmed flat blank is to be written. See OP20 in Figures 26-4, 26-22 and 26-3 . |

Card Set for *INTERFACE_BLANKSIZE_INITIAL_ADAPTIVE.

Flat blank. FILENAME9 specifies the mesh of a blank in a flat configuration serving as the basis for a two-step metal forming process. The second-stage simulation produces an adapt.msh file, from which the refinements are to be mapped onto the flat-blank of FILENAME9. See, for example, “OP20 Flat New” in [Figure 26-3](#) where FILENAME9 points to result, FILENAME8, of an INITIAL_TRIM calculation.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----------|---|---|---|---|---|---|---|
| Variable | FILENAME9 | | | | | | | |
| Type | A80 | | | | | | | |

Initial blank. FILENAME10 is the result from the first stage of a two-step process. See, for example, “OP30 Initial blank” in [Figure 26-3](#) where FILENAME10 has been formed and trimmed and refined along the way.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------------|---|---|---|---|---|---|---|
| Variable | FILENAME10 | | | | | | | |
| Type | A80 | | | | | | | |

Adapted Initial blank. FILENAME11 contains a refined version of the mesh in FILENAME10. It is expect to name the adapt.msh file from some operation performed on the mesh of FILENAME10. See, for example, “OP30 Initial blank (with more mesh)” in [Figure 26-3](#), where the adapt.msh file comes from a flanging simulation.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------------|---|---|---|---|---|---|---|
| Variable | FILENAME11 | | | | | | | |
| Type | A80 | | | | | | | |

Refined Flat blank (output). This field specifies the name of the file to which the refined flat blank is written. The blank's mesh is refined to *exactly* match the forming process. See, for example, "OP30 Flat New" in [Figure 26-3](#).

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------------|---|---|---|---|---|---|---|
| Variable | FILENAME12 | | | | | | | |
| Type | A80 | | | | | | | |

| VARIABLE | DESCRIPTION |
|------------|--|
| FILENAME9 | FILENAME9 should point to the blank defined by FILENAME8, as in Figures 26-4, 26-22 and 26-3 . |
| FILENAME10 | <p>Initial-stage result file name. This may be extracted from d3plot files using LS-PrePost or it may be generated by LS-DYNA as a dynain file. See, for example, "OP30 Initial Blank" in Figure 26-3 where FILENAME10 has been formed, trimmed and refined along the way.</p> <p>To obtain from d3plot file the necessary mesh in keyword format using LS-PrePost4.0 select <i>POST</i> → <i>OUTPUT</i> → <i>Dynain ASCII</i> and check the box for <i>Exclude strain and stress</i>.</p> |
| FILENAME11 | FILENAME11 contains a refined version of the mesh in FILENAME10. FILENAME11 can be obtained from adapt.msh file from the same operation performed on the mesh of FILENAME10. See, for example, "OP30 Initial Blank (with more mesh)" in Figure 26-3 , where the adapt.msh file comes from a flanging calculation. |
| FILENAME12 | This field specifies the name of the file to which the refined flat blank is written. The blank's mesh is refined to <i>exactly</i> match the forming process. See, for example, "OP30 Flat New" in Figure 26-3 . |

Card Set for *INTERFACE_BLANKSIZE_SCALE_FACTOR.

Scale Factor Card. Define one card for each curve. Include as many cards in the following format as desired. This input ends at the next keyword ("**") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-----|------|------|------|---|---|---|
| Variable | IDCRV | SF | OFFX | OFFY | OFFZ | | | |
| Type | I | F | F | F | F | | | |
| Default | 1 | 0.0 | 0.0 | 0.0 | 0.0 | | | |

VARIABLE**DESCRIPTION**

IDCRV

Curve ID in the order of appearance as in FILENAME1 in the target card, as defined by *DEFINE_TARGET_BOUNDARY.

SF

Scale factor for the IDCRV defined above. It defines a fraction of the changes required for the predicted initial blank shape.

For example, if SF is set to 0.0, the corresponding IDCRV will be excluded from the calculation (although the original initial curve still will be output); on the other hand, if SF is set to 1.0, full change will be applied to obtain the modified initial blank that reflects the forming process. A SF of 0.5 will apply 50% of the changes required to map the initial blank. This feature is especially important for inner holes that are small and hole boundary expansions are large, so the predicted initial hole can avoid "crisscross" situation. An example is provided in [Scale Factor and Symmetric Plane](#).

OFFX, OFFY,
OFFZ

Translational move of the target curve. This is useful when multiple target curves (e.g. holes) and formed curves are far away from each other. Input values of OFFX, OFFY and OFFZ helps establish one-to-one correspondence between each target curve and formed curve.

OFFX.EQ.-10000.0: offset values are automatically calculated.

Card Set for *INTERFACE_BLANKSIZE_SYMMETRIC_PLANE.

Symmetric Plane Card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-----|-----|---|---|
| Variable | X0 | Y0 | Z0 | V1 | V2 | V3 | | |
| Type | F | F | F | F | F | F | | |
| Default | 0.0 | 0.0 | 0.0 | 1.0 | 0.0 | 0.0 | | |

VARIABLE

DESCRIPTION

X0, Y0, Z0

x, y, z coordinates of a point on the symmetric plane. See example in [Scale Factor and Symmetric Plane](#).

V1, V2, V3

Vector components of the symmetric plane's normal. See example in [Scale Factor and Symmetric Plane](#).

Remarks and Examples**Inverse Methods for Optimizing Blank Size and Trim Lines:**

Finding the minimal practicable blank size and developing an optimal set of trim lines is an integral part of the die engineering process. This card, *INTERFACE_BLANKSIZE, is one of several features that have been developed to solve the inverse problem: that is, to calculate an initial blank or blank boundary that will yield a desired product based mostly on the target geometry of that final product.

1. **The One-Step Method.** The *CONTROL_FORMING_ONESTEP card is suitable for early blank-size estimates. It invokes the total-strain theory of plasticity, thereby bypassing the, as of yet, undetermined specific details of the forming process.
2. **Unflanging.** Once the product design and process plan are complete, die development begins with addendum and binder creation, followed by secondary tooling development. In this stage, *CONTROL_FORMING_UNFLANGING can be used to develop trim lines for the secondary tooling; final (or intermediate) desired flange shapes are unfolded onto the addendum or binder to obtain the corresponding flange shapes in its initial shape. It also implements failure criteria to arrive at suggested final flange curves, with strains and thickness output on the unfolded flanges.
3. **Interface Blanksize.** This card, *INTERFACE_BLANKSIZE, can be used to *accurately* determine the optimal initial blank. To do so it requires an initial configuration, the corresponding simulated configuration, and a desired target configuration. This method takes into account the entire metal-forming process.
 - a) One application of this keyword is to map trim curves between dies to calculate the trim curves needed for all trim dies. An example of the application can be found in [Figures 26-18](#) through [26-21](#).

| | Computational Cost | Accuracy | Information Required | Physical Process |
|------------|--------------------|-------------|-------------------------------------|------------------|
| Blanksize | Full simulation | Exact | Full Simulation | Any |
| Unflanging | Fast | Approximate | Process Geometry | Inverse Flanging |
| Onestep | Fast | Approximate | None (<i>Path independent</i>) | Any |

Table 26-1. Comparison of inverse methods.

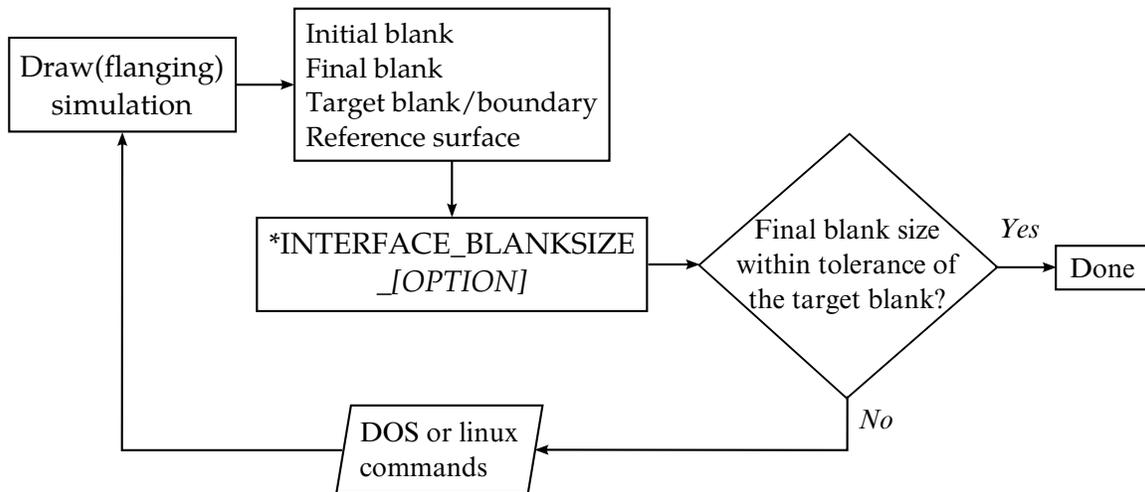

Figure 26-5. An iterative blank size development process.

- b) The keyword can also be used to determine the precise minimal initial blank needed for a draw panel whose blank edge must be at specified distances from the edge of the draw beads.

Iterative Workflow:

The “interface blanksize” command produces an adjusted initial blank. It is not to be expected that the adjustment will be exact. However, this initial blank shape can be run through a second simulation to see if the final shape is close enough to the target blank. If it is not close enough, then the results from the second simulation can be used to repeat the process. Iterations can proceed until the final shape is within the range of the target shape. This iterative blank size development process is schematically presented in [Figure 26-5](#) and exemplified in [Figures 26-8](#) through [26-17](#).

Target Boundaries (and IGES):

When IOPTION = 2, or -2, a file with the keyword *DEFINE_TARGET_BOUNDARY must be present. This keyword can now be created from an IGES file using LS-PrePost 4.1 (or 4.2). To convert from IGES curves to keyword *DEFINE_TARGET_BOUNDARY in LS-PrePost 4.1, use menu option *Curve* → *Convert* → *Method (To Keyword)* → *Select *DEFINE_TARGET_BOUNDARY*; pick the curves then hit *To Key*; write out the keyword file using *File* → *Save as* → *Save Keyword As*; and select *Output Version* as *V971_R7*. In LS-PrePost 4.2, select *Application* → *Metal Forming* → *Blanksize Trimline* to import the target curve directly in IGES format, the initial and final blank mesh and then write out a complete LS-DYNA input deck.

In addition, the target curves should be projected onto the final blank mesh if they do not exactly lie on the mesh surface. This can be done with LS-PrePost 4.1 using the

menu option *GeoTol* → *Project* → *Project*, select *Closest Projection*, select *Project to Elements*, then define the destination mesh and source curves, and hit *Apply*.

Computed Initial Blank Boundaries (and IGES):

Computed boundary curves are written with `*DEFINE_CURVE_TRIM_3D` keyword into a file called `trimcurves.ibo`. The format of this file follows the keyword's specification. LS-PrePost4.0 can convert the computed curve to IGES. See [Figure 26-10](#). After hitting *Apply*, the curves will show up in the graphics window, and *File* → *Save as* → *Save Geom as* can be used to write the curves out in IGES format. In the LS-PrePost 4.2 GUI, under *Results*, `trimcurves.ibo` can be directly imported into the graphics window for viewing and to save in either STEP or IGES format.

To convert IGES to the `*DEFINE_CURVE_TRIM_3D` keyword format, import the IGES file into LS-PrePost4.0 and follow the procedures shown in [Figure 26-11](#). After finishing step 2, "*curves have been converted to keyword format*" will be reported in the command prompt. Then use *File* → *Save* → *Save keyword* to write out the keyword file.

Support for Multi-Stage Processes with the Development Option:

Original Implementation.

Prior to Revision 88708 the development option required that the final blank (FILENAME2) differ from the initial blank (FILENAME3) by no more than a deformation and mesh refinement. In practice, this means that the two meshes must come from the same process simulation. For example, in a draw, trim and flanging process, the trimmed panel mesh is used for flanging simulation. Therefore, with the original implementation, LS-DYNA required that the initial blank state (FILENAME3) be trimmed when the final blank state (FILENAME2) is flanged on trimmed panel. Failure to observe this limitation may result in error termination.

Enhanced Implementation.

A more recent improvement to the blank size development (Revision 88708) removes the requirement that initial (FILENAME3) and final (FILENAME2) blanks must be from the same process simulations. The initial and final blank states *may* differ by a trimming process. This allows trimming and other process such as flanging to occur between the initial and final blanks, without the need of invoking the `INITIAL_TRIM` and `INITIAL_ADAPTIVE` options. For example, the initial blank can be the blank mesh from "Blanking" in [Figure 26-4](#), and the final blank can be the blank mesh from "Flanging," which is also in [Figure 26-4](#).

Scale Factor and Symmetric Plane:

An example of using various scale factors ranging from 0.0 to 1.0 on a model involving an initial hole shape is shown in [Figure 26-25](#). The target curve is given in targetline.k. All nodes along the symmetric plane are constrained by the SYMMETRIC_PLANE option. The symmetric plane is defined going through point coordinates (-76,2.63844,0.38) with plane normal vector of (1.0,0.0,0.0). A complete input is provided below:

```
*KEYWORD
*INTERFACE_BLANKSIZE_DEVELOPMENT
$ IOPTION          IADAPT
   -2              1
$ target boundary curves
targetline.k
$ final formed mesh
final.k
$ initial mesh
initial.k
*INTERFACE_BLANKSIZE_SCALE_FACTOR
$   IDCRV          SF
   1              0.2
*INTERFACE_BLANKSIZE_SYMMETRIC_PLANE
$   X0             Y0             Z0             V1             V2             V3
   -76            2.63844         0.38          1.0            0.0            0.0
*END
```

If targetline.k consists of multiple curves, the following format can be used:

```
*INTERFACE_BLANKSIZE_SCALE_FACTOR
$   IDCRV          SF
   1              0.2
   2              0.8
   3              1.0
   ⋮              ⋮
```

Example I: Simple Example of the Development Option

Given the initial and final blank configuration and a target, this option calculates a new initial blank outline, corresponding to the target final blank boundary. In this example note that IADAPT = 1, meaning initial and final blank meshes may differ by an adaptively operation. The input and output files are detailed below, and output results are shown in [Figure 26-6](#).

```
*KEYWORD
*INTERFACE_BLANKSIZE_DEVELOPMENT
$ IOPTION          IADAPT
   2              1
$ input file for target mesh, or target position coordinates
targetpoints.k
$ input file for formed mesh
final.k
$ input file for initial blank mesh
initial.k
*END
```

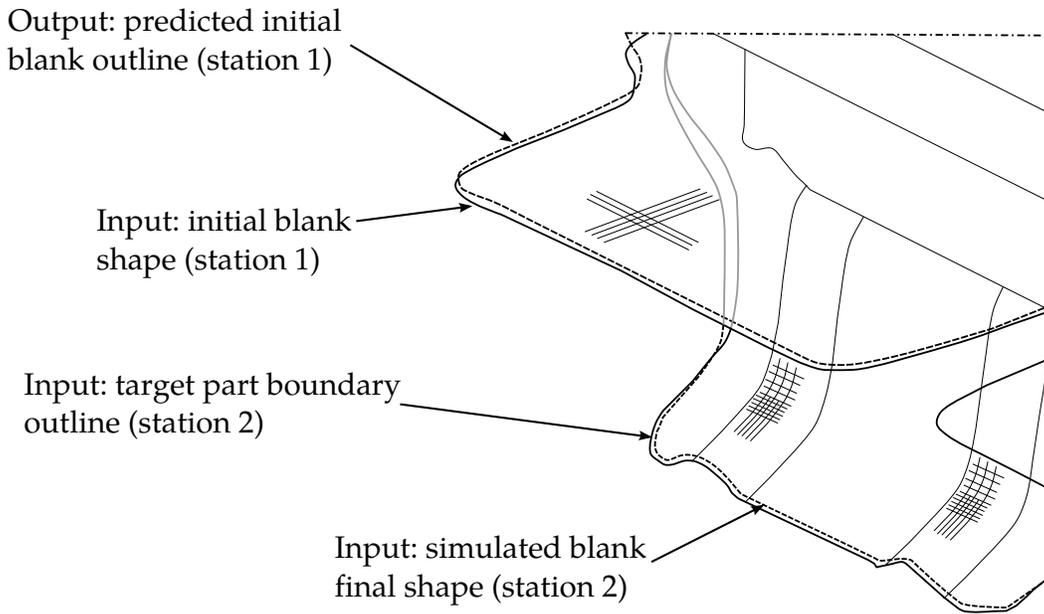

Figure 26-6. Blank size development in a progressive die with IADAPT = 1 in Example I.

The file, targetpoints.k partially shown below, was generated from IGES using *LS-PrePost 4.1*.

```
*KEYWORD
*DEFINE_TARGET_BOUNDARY

  ⋮
-1.83355e+02 -5.94068e+02 -1.58639e+02
*END
```

The output is the modified initial blank outline in the file trimcurves.ibo.

Example II: The Reference Surface feature for the Development Option

For an initial blank that is not flat, the fields REF and FILENAME4 can be used to define a surface onto which changes in the boundary are needed. This is important when the adjusted boundary is not a simple tangential extension of the initial blank.

In a keyword example below, REF is set to "1" and the reference file for the extended initial shape is given as ref3.k. The maximum change between the initial and final blank size is set to be 20.0 mm per iteration. Point spacing distance (SPACE) of the calculated trim curve on the reference surface is set at 2.0 mm. Note that the inner holes and outer boundary curves are defined in target.xyz. The holes do not necessarily need to exist in the initial or final blank mesh. Also, since ORIENT is set to 2, a reference

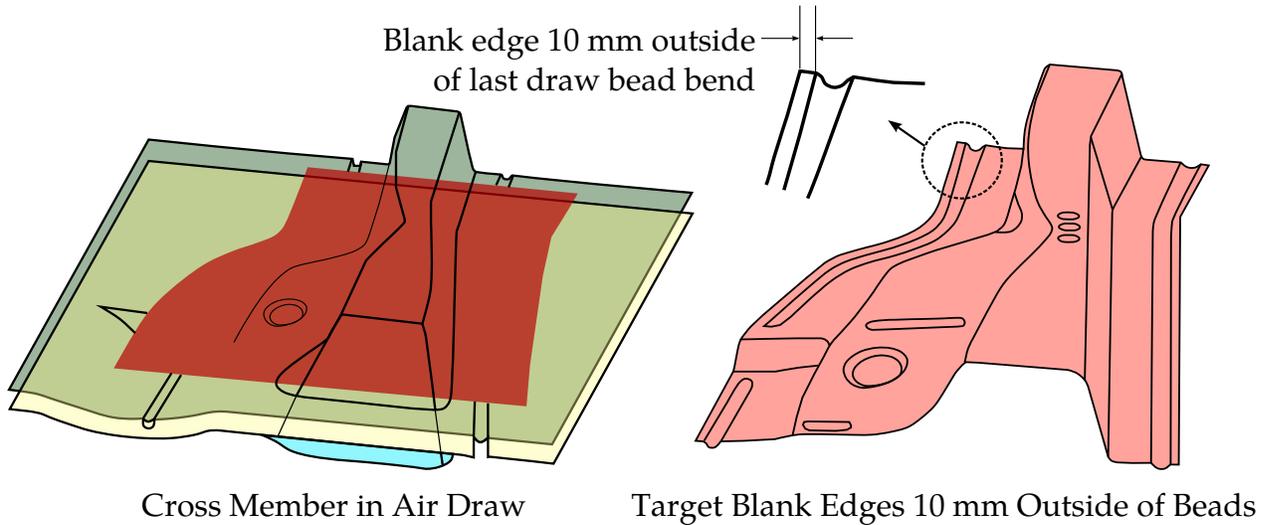

Figure 26-7. NUMISHEET 2005 cross member in Example III.

surface mesh file (ref4.k) is provided for the final (formed) state. The input details and output results are shown in Figure 26-1.

Example III: Development Feature Applied to a Draw Die with Physical Bead

In this example, which was created from NUMISHEET 2005, the DEVELOPMENT option has been used to design a blank such that, when formed, the edge is a specified distance outside of the last bend of a draw bead. In Figure 26-7, the tooling and blank set up is shown on the left. The right side of the figure shows the target blank, whose left and right edges everywhere are made 10 mm outside of the last bending radius of the draw beads. This setup is prototypical of one method to ensure a very stable and high-quality stamping process.

The first step towards setting up this analysis was to use *CONTROL_FORMING_ON-ESTEP to unfold the target blank and thereby obtain an initial guess of a flat blank, as shown to the left in Figure 26-12. The flat blank is then formed as one would usually do

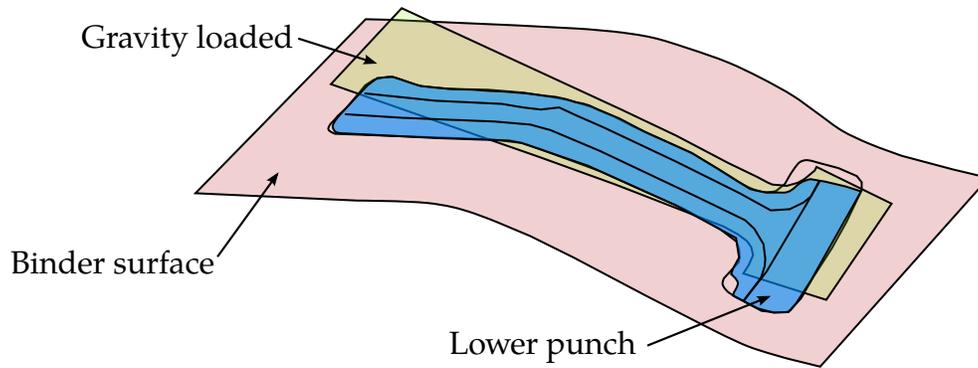

Figure 26-8. NUMISHEET 2008 B-pillar; Gravity loaded blank.

in a regular forming simulation as shown on the right side of the figure. The formed blank (Iteration 0) turns out to be larger than the target.

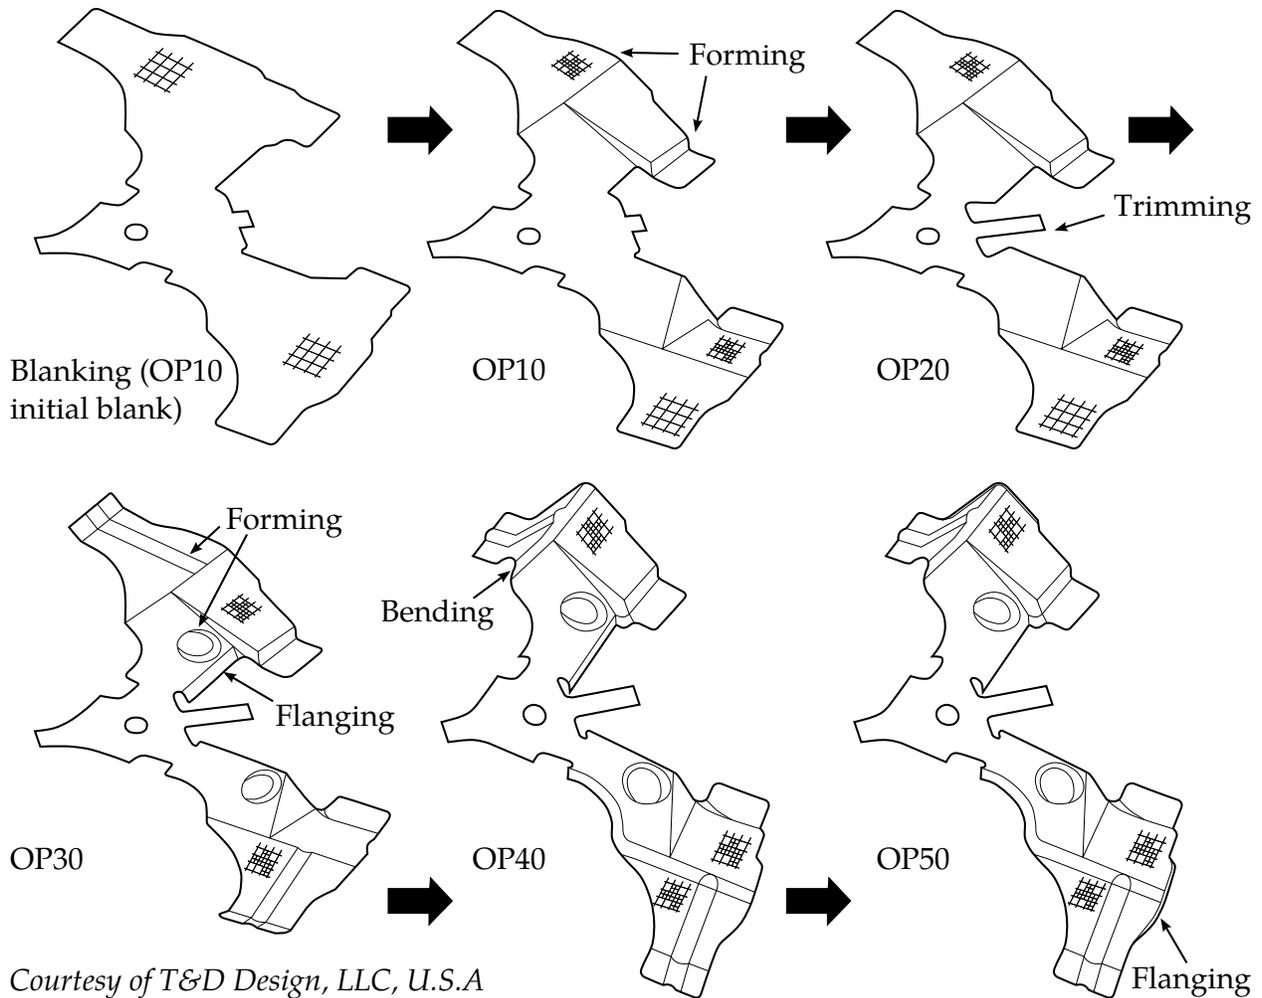

Next, the DEVELOPMENT is applied to generate a new and better initial blank that will lead to the target blank. The flat blank is used as input for the "initial blank mesh", the formed blank is used as input for the "simulated mesh", and the target blank mesh, or boundary points, is used to define the target.

In [Figure 26-13](#) (left) the improved initial blank, called *the first compensated blank*, is superimposed onto the original one-step unfolded result. The one-step unfolded result is somewhat larger than the developed blank. When formed the improved blank (Iteration 1) nearly overlaps the target blank, shown in [Figure 26-13](#) (right). If the final formed blank still deviates from the target, another iteration would ensue, until satisfactory results are obtained.

Example IV: Iterating with the Development Option

Because the NUMISHEET 2008 B-pillar model involves neither trimming nor flanging, it exemplifies the DEVELOPMENT option in its most direct use case. This model, illustrated in [Figure 26-8](#), simulates a draw-die's action on a gravity-stressed flat blank. The B-pillar undergoes a stamping process including gravity, binder closing, and being drawn. In this example the DEVELOPMENT option is used to calculate the geometry for an initial blank that will exactly satisfy the design specification for a final formed panel. To highlight the efficiency of this feature, we start with an initial blank whose formed product deviates from the specification by a wide margin and then iterate using the DEVELOPMENT feature.

The target and the optimal initial blank are shown in [Figure 26-14](#). The initial guess intentionally deviates from the optimal initial blank as shown in the left panel of [Figure 26-15](#); the formed blank is compared with the target in the right panel.

Courtesy of T&D Design, LLC, U.S.A

Figure 26-9. Enhanced DEVELOPMENT feature on a progressive die. Even though trimming occurs at OP20, the algorithm requires as input only OP10, OP50, and a target geometry.

In the first iteration a new initial blank is computed, and illustrated in the left panel of [Figure 26-16](#), bearing the label *1st compensated blank*. The simulation is repeated using the first compensated blank, and in the right panel the result is compared to the target. The formed blank is narrower in the notched areas as compared with the target.

The second iteration is shown in the left panel of [Figure 26-17](#) bearing the label, *2nd compensated blank*. Again, the simulation is repeated, but this time using the second compensated blank, and the result is compared to the target in the right panel of [Figure 26-17](#). The resulting product is a good match to the target.

Because the initial blank intentionally deviated from its ideal shape by a large margin, this example requires two iterations to converge. Generally this process is bootstrapped with the *CONTROL_FORMING_ONESTEP card, which calculates an initial guess by approximately unfolding the target shape.

Example V: Development Feature Applied to Flanging Process

In this example, which is schematically illustrated in [Figure 26-18](#), the NUMISHEET 2002 fender outer is flanged along the hood line. The development feature adjusts the initial blank's boundary so that the formed piece matches the specified target flanged shape as shown in [Figure 26-19](#). For demonstration purposes, the trimmed blank shape intentionally deviates from the optimal configuration by a large amount. This error is indicated in [Figure 26-20](#) by the label *initial guess trim curves*. In [Figure 26-20](#) the flanged product is shown to deviate substantially from the flanged target along the boundary. As shown in [Figure 26-21](#) after one iteration the correct initial blank boundary is obtained.

Alternatively, `*CONTROL_FORMING_UNFLANGING` can be used to unfold the flanged target onto the addendum to obtain the initial blank size, or a starting guess for this process.

Example VI: Enhanced-Development Feature Applied to Progressive Die Process

In the example of [Figure 26-9](#), *courtesy of T&D Design, LLC, U.S.A*, the blank-shape for a five stage progressive die process is calculated. Because this process involves a trimming step, the development capability prior to Revision 88708 does not support this example.

In this example, an initial blank at OP10, undergoes trimming, reforming, bending and flanging to arrive at the blank in OP50. In [Figure 26-23](#) the computed product is compared with the specified target. A blank size development calculation produces the modified OP10 initial blank outline. The updated blank is used in a verification simulation. As seen in [Figure 26-24](#), the blank size development feature produces a good result.

Trim lines are not optimized by the development feature, so trimming should only occur along the boundary of the target blank. The modified OP10 blank requires some refitting in the trimmed area.

Revision information:

This feature is available in both SMP and MPP, in double precision only. Note a GUI for using this feature is now available in *LS-PrePost* as of version 4.2. It can be accessed under APPLICATION → Metal Forming → Blank Size/Trim line Dev. Starting revision information for each feature is listed as follows:

1. DEVELOPMENT option: Revision 74605.
2. INITIAL_TRIM and INITIAL_ADAPTIVE: Revision 75023.

3. IADAPT: Revision 75827.
4. Command line option "JOBID=...": Revision 82861.
5. MAXSIZE: Revision 85633.
6. SPACE: Revision 85755.
7. MAXGAP: Revision 85792.
8. Reference surface (parameter REFERENC): Revision 86086.
9. Removal of the restriction requiring the initial (FILENAME3) and the final (FILENAME2) blanks must be from the same process simulation: Revision 88708.
10. Improve smoothness of the output trim curve trimcurves.ibo in case the given meshes have warpage caused by wrinkles during forming: Revision 96164.
11. Symmetric plane: Revision 97443.
12. Scale factor: Revision 98122.
13. ORIENT = 1: Revision 100453.
14. ORIENT = 2: Revision: 104168.
15. Curve direction is desensitized, meaning both IOPTION = 2 and IOPTION = -2 will give the same results: Revision 100589.
16. OFFX, OFFY, OFFZ: Revision 100660.
17. Automatically calculate offset values (OFFX.EQ.-10000.0): Revision 102609.

***INTERFACE_COMPENSATION_3D_{OPTION}**

Available options include:

<BLANK>

ACCELERATOR

MULTI_STEPS

LOCAL_SMOOTH

PART_CHANGE

REFINE_RIGID

FLANGE

Purpose: The springback compensation module is implemented to automatically modify the rigid tools to compensate for the springback deviations. Since springback compensation is not a linear problem, an iterative approach is proposed that usually requires two to three iterations to bring the deviation below the tolerance.

To use this module, the user needs to provide the following information: a) the target, which is the deformed part with the original unmodified tool; b) the current tool file at its home or final position; c) the part shape formed with the current tool; d) the part shape after springback with the current tool; and e) a bridging file from the previous compensation, (for the first compensation the target file is used, then a file named `disp.tmp` is generated and will be used for the next iteration). To make the inclusion order-independent, five keywords are used to include the files mentioned above:

- a) `*INCLUDE_COMPENSATION_DESIRED_BLANK_SHAPE`
- b) `*INCLUDE_COMPENSATION_CURRENT_TOOLS`
- c) `*INCLUDE_COMPENSATION_BLANK_BEFORE_SPRINGBACK`
- d) `*INCLUDE_COMPENSATION_AFTER_SPRINGBACK`
- e) `*INCLUDE_COMPENSATION_COMPENSATED_SHAPE`

Depending on the die set-up, different kinds of compensation are required. For example, sometimes the binder is not allowed to be modified. To meet this need, various compensation methods are available. The most commonly used methods are 6, 7, and 8. Linear and non-linear methods are also available to modify the tool surface outside the blank outline.

The applications for this card include: (1) calculating the deviation of the stamped part from its intended design and automatically compensating the tool to minimize the deviation; (2) mapping the existing trim curve to the modified tool; and (3) automatically detecting undercut. This keyword requires the double precision version of LS-Dyna. Note that the current methods sometimes fail to eliminate undercut.

| |
|--|
| <p>NOTE: The keyword <code>*INTERFACE_COMPENSATION_3D</code> replaces <code>*INTERFACE_COMPENSATION_NEW</code> starting in Revision 115517.</p> |
|--|

This feature is implemented and available in LS-PrePost 4.3 under Application → Metal Forming → Easy Setup.

The `ACCELERATOR` option speeds up the convergence rate of compensation. This option also allows for a much simpler user interface.

The `MULTI_STEPS` option allows for tooling compensation of the next die process, based on target blank shape, compensated blank shape for the next step, and current tools. This feature is useful in line die process/tooling compensation.

The `LOCAL_SMOOTH` option features smoothing of a tool's local area mesh, which could become distorted because of a bad or coarse mesh of the original tool surface, a non-constant gap between tooling pairs (for example, flanging post and flanging steel), or a few compensation iterations. This option also requires using `*SET_NODE_LIST_SMOOTH`.

The `PART_CHANGE` option allows for updating of the final compensated tool using the changed part or formed blank shape, thus eliminating the need for going through a new compensation iteration loop. This option is used together with `*INCLUDE_COMPENSATION_UPDATED_BLANK_SHAPE`, and `*INCLUDE_COMPENSATION_UPDATED_RIGID_TOOL`.

The `REFINE_RIGID` option refines the rigid tool mesh and aligns the nodes along the user-provided trim curves. The required input will be the original tool mesh and trim curves. This option ensures subsequent compensation of the tool to extend all the way to the trim curves. Note this option does not physically change the shape of the tool, but the refined and realigned tool mesh at the trim curves will greatly improve the compensation convergence in the iterative process. This option only needs to be done once before the iterative springback compensation begins.

The `FLANGE` option defines flanging steel's moving direction and can be used in springback compensation of a flanging process.

Card Summary:

Card 1a.1. This card is included if and only if the option is <BLANK>, MULTI-STEPS, or LOCAL_SMOOTH.

| Card 1a.1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | METHOD | SL | SF | ELREF | PSIDM | UNDCT | ANGLE | NLINEAR |
| Type | I | F | F | I | F | F | F | I |
| Default | 6 | 5.0 | 0.75 | 1 | none | 0 | 0.0 | 1 |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| METHOD | There are several extrapolation methods for the addendum and binder outside of trim lines; see Compensation Methods Overview . |
| SL | The smooth level parameter controls the smoothness of the modified surfaces. A large value makes the surface smoother. Typically, the value ranges from 5 to 10. If springback is large, the transition region is expected to be large. However, by using a smaller value of SL, the region of transition can be reduced. |
| SF | Shape compensation scale factor. The value scales the springback amount of the blank and the scaled amount is used to compensate the tooling. GT.0: compensate in the opposite direction of the springback; LT.0: compensate in the punch moving direction (for undercut). This scale factor determines how much the shape deviation is compensated, and a favorable value can reduce the number of iterations. However, the right value is case dependent. Usually, SF is chosen between the range of 0.75 and 1.25. |
| ELREF | Element refinement option: EQ.1: special element refinement is used with the tool elements (default); EQ.2: special element refinement is turned off. |
| PSIDM | Define the part set ID for master parts. It is important to properly choose the parts for the master side. Usually, only one side (master side) of the tool will be chosen as the master side, and the modifications made to the other side (slave side) depends solely on the changes in the master. This allows the two sides to be coupled and a constant (tool) gap between the two sides is maintained. If both sides are chosen to be master, the gap between the two sides might change and become inhomogeneous. When using METHOD 7, the choice of master side will affect the result when applied to three-piece draw models. At this time, when the punch and binder are chosen as the master side, the binder region will not be changed. Otherwise, when the die is chosen as master side the binder will be changed, since the changes extend to the edges of the master tool. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| UNDCT | Tool undercut treatment option: EQ.0: no check (default); EQ.1: check and fix undercut. |
| ANGLE | An angle defining the undercut. |
| NLINEAR | Activate nonlinear extrapolation. |

This card is included if and only if the option is <BLANK>.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| PID | The part ID of the flanging steel to be compensated. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| VX, VY, VZ | The vector components of the flanging steel's (PID) moving direction. |

Compensation Methods Overview:

After trimming, only a limited part of the tool has direct relationship with the springback of the blank part. Modifications of the rigid tool outside the trimmed region involves extrapolation. Unfortunately, extrapolating is unstable and tends to generate non-smooth surfaces. To resolve this problem, seven smoothing algorithms are implemented. The most frequently used methods are methods 7, 8 and -8, while the others are used only occasionally.

Method 7

If the punch is chosen as the master side, the binder will not be changed. Aside from the region inside the punch opening, the rest of the model is untouched. Smoothing has little effect on method 7. The smoothness of the modified tool depends on the magnitude of the springback and the size of the addendum region. This method is nonlinear and, therefore, necessitates an iterative solve.

Advantages: The binder will not be changed.

Disadvantages: The change will be limited inside the addendum region, and the modified surface may not be smooth if the springback magnitude is large and the transition is small.

Method 6

The smoothness and the transition region of the modified surface will depend on the springback magnitude and the smoothing factor. If the springback magnitude is large, the transition region will be increased automatically. On the other hand, the transition region will be smaller if the springback magnitude is small. At the same time, a larger smoothing factor will result in a smaller transition region. Like method 7, this too is nonlinear.

Advantages: The smoothness of the modified surfaces can be controlled.

Disadvantages: It is impossible to limit the transition region, and the binder surface (and therefore, draw beads) could change if the spring back is large.

Method 3

Similar to Method 6, however, it is a linear method and no iteration is necessary.

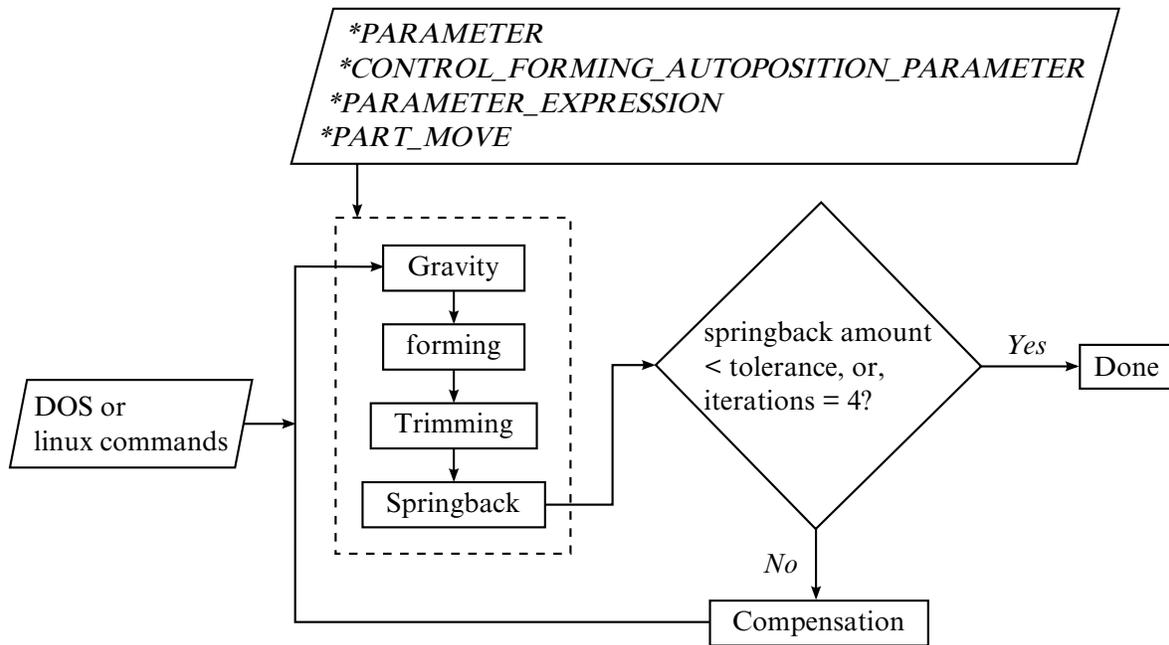

Figure 26-26. Iterative compensation flow chart

Method 8

This is an enhanced version of Method 6, and can account for addendum and binder changes. Usually the upper tooling including addendum and binder (in an air draw) are included in the PSIDM definition.

Method -8

This method is a modification of Method 8, and is used for trim die nesting (from the drawn panel shape).

Methods 1, 2, 4, and 5

These methods are deprecated and may be removed in the future. They are included only for maintaining backwards compatibility.

Preventing Undercut:

When the draw wall is steep, it is likely that undercut will occur. Since undercut is not acceptable in real world die manufacturing, it must be prevented.

The compensation code can automatically detect undercut and issue a warning message. Additionally, LS-DYNA will write a list of undercut elements to a file called blankundercut.tmp so that the user can easily identify which elements may be problematic.

If the undercut is limited to only a few elements, it is possible to fix the problem manually.

Undercut can be reduced by compensating the springback only in the punch moving direction (by using a negative scale factor). This method is not 100% reliable and more robust solutions are being studied.

Iterative Springback Compensation:

Figure 26-26 illustrates the iterative springback compensation algorithm as applied to a typical stamping process. The first stamping process simulation is done following gravity → forming → trimming → springback (ITERATION 0). The stamping process simulation is set up using eZ-Setup in LS-PrePost. By using the parameterized automatic tool/blank positioning feature, the process simulation is fully automated (no user intervention required). Based on the calculated springback amount, tooling geometry is compensated through a compensation run. The stamping process simulation is conducted again, automatically, based on the new compensated tooling, followed by a second tooling compensation (ITERATION 1). Iterations 2, 3, and 4 follow the same pattern. The iteration process is repeated until the blank springback shape conforms to the target shape, or until it reaches 4 iterations (typically required to achieve part tolerance). With some shell scripting this iterative loop can be completed automatically. These tools allow the user to toggle between the single and double precision version of LS-DYNA.

The task of tracking the files involved in the iterative process can be daunting, especially in the advanced stage of the iterations. Figure 26-27 indicate what is written to storage during the process.

An input deck defining a springback compensation model is given below. The keyword file blank0.k includes node and element information of the blank shape before springback (after forming and trimming) with adaptive constraints (if exist). The keyword file spbk.k includes node and element information of the blank after springback, with adaptive constraints (if they exist). The blank shapes before and after springback (blank0.k and spbk.k) may be based on either the original die design (ITER0), or based on an intermediate compensated die design (say the nth iteration).

The keyword file reference0.k is the blank shape before springback for iteration 0 (ITER0). This file is blank0.k and should *not* change from iteration to iteration. For iteration 0 the file reference1.k is also the same as blank0.k, but for iteration 1 reference1.k should be the disp.tmp generated from the compensation calculation during iteration 0 and so on and so forth for the subsequent iterations.

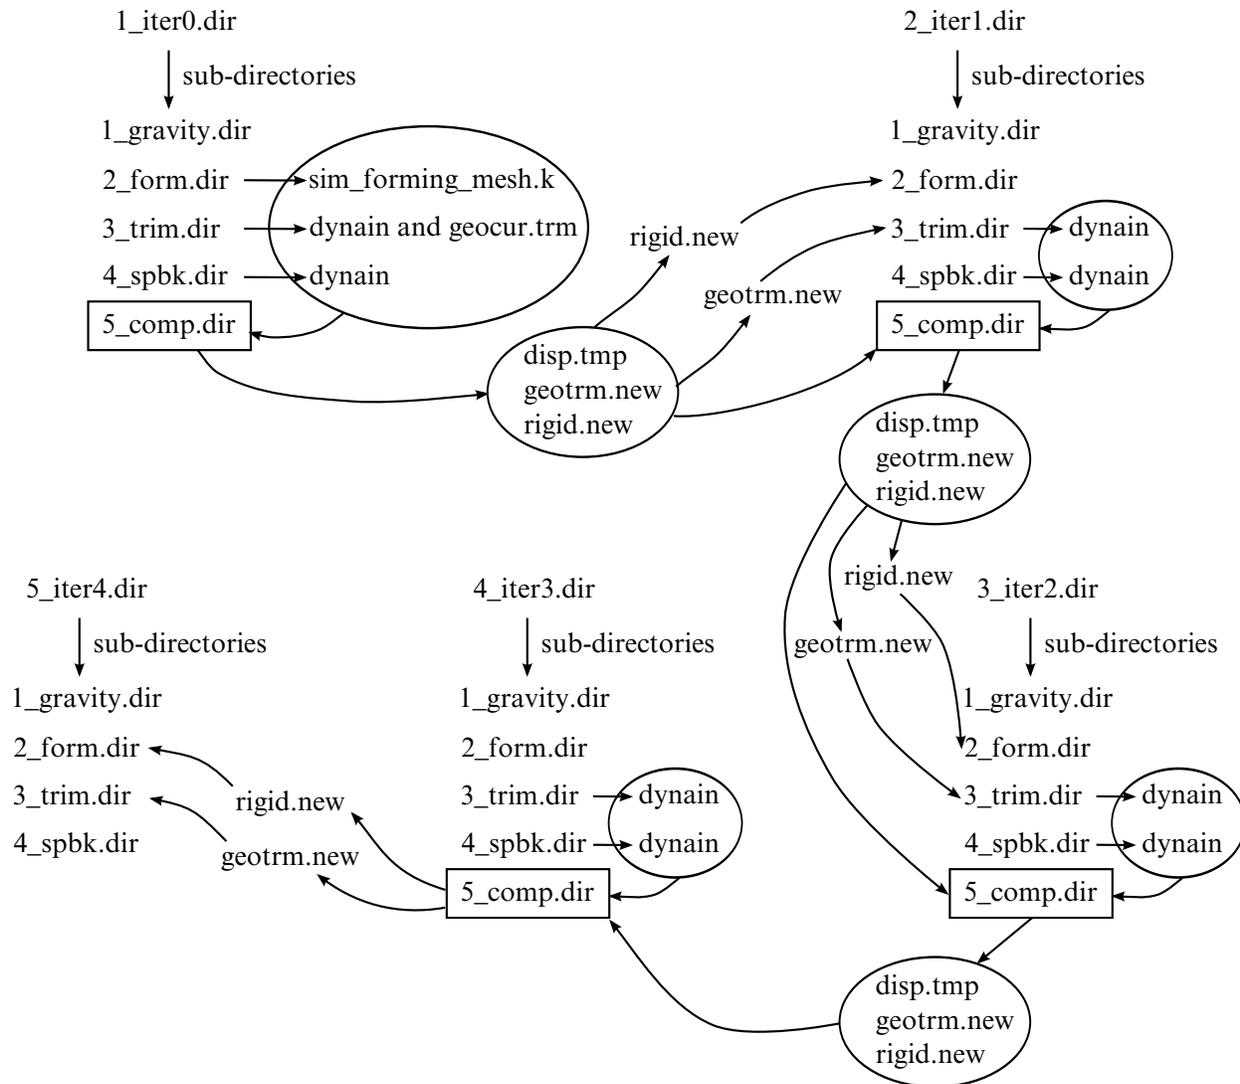

Figure 26-27. File structure for compensation

The keyword input `tools.k` must contain the mesh information for all of the stamping tools in their home positions. Compensated tools will be written to `rigid.new` with the original constant gap being maintained among the tools. During the baseline calculation, iteration 0, a keyword file called `geocur.trm` is generated during a LS-DYNA trimming simulation based on trimming curve input (usually in IGES format). During the compensation run of ITER1, `geocur.trm` is used to generate new trim curves which are output in `geotrm.new`. The new curves conform to the current compensated tools and are used for the next iteration. The new trim file, `geotrm.new`, is also in keyword format and contains a `*DEFINE_CURVE_TRIM_3D` card.

The example below models a three-piece air draw process. The upper die cavity (including binder) has a part ID 2, which is included in the part set ID 1 and is used for variable PSIDM. Method 8 will compensate all the tools included in file `tools.k` based on compensated shape for the upper cavity.

An NUMISHEET 2005 Example:

In [Figure 26-28](#), the NUMISHEET 2005 cross member is compensated following the flow chart. In two iterations the springback is reduced from 13mm to 1.7mm. Further iterations will reduce the part deviation down to a specific design target. Typically, four iterations are needed.

Iterative Compensation Applied During Die Construction:

The blank shape after springback can be obtained from the actual experimental shape of the springback panel, if available. For example, in hard tool construction, the trimmed panel can be scanned using white light technology and the panel shape can be written to an STL file. The STL format can be easily converted to LS-DYNA keyword format and the trimmed panel can be used as a rigid tool onto which the baseline (ITER0) trimmed panel (deformable) can be “pushed” using element normal pressure, and using *CONTROL_IMPLICIT_FORMING type 1. In this scenario, the adaptive refinement is turned off to maintain the one-to-one correspondence of the elements and nodes information. An advantage of this method is that the springback shape used for compensation will be exactly the same as the actual panel springback; therefore, the best tooling compensation result is expected. An example of such is shown in [Figures 26-29](#) and [26-30](#).

Compensation of Localized Regions:

Compensation of a localized tooling region is possible, with the keyword `*INCLUDE_COMPENSATION_CURVE`, by incorporating the following lines into the above example inputs:

```
*INCLUDE_COMPENSATION_CURVE
curves.k
```

The file `curves.k` defines the two enclosed “begin” and “end” curves using `*DEFINE_CURVE_COMPENSATION_CONSTRAINT_BEGIN/END`. A more in depth explanation can be found in the corresponding keyword manual entries. In [Figure 26-31](#), the NUMISHEET’05 decklid inner is compensated locally in the horizontal area above the backlite. Tangency of the compensated tool is maintained at the “End Curve” as shown in the section A-A. Also shown in [Figure 26-32](#) includes color contours of part-separation distance throughout the iterations between compensated panel and the target design intent. Part tolerance is achieved in two iterations.

Accelerated Springback Compensation (ASC):

The option `ACCELERATOR` can be used in conjunction with `*INCLUDE_COMPENSATION`, with options `ORIGINAL_DYNAIN` and `SPRINGBACK_INPUT` to compensate springback with a faster convergence rate and a simplified user interface. A complete example is provided below. The example uses a spring back input file `spbk.dyn`, and a trimmed panel, with file name `case20trimmed.dynain` (including all stress and strain tensors and adaptive constraints). The variable `ISTEPS` is increased from 0 to 3, representing 3 compensation iterations. `ISTEPS = 0` represents the baseline springback simulation (`ITER0`), while `ISTEPS = 1, 2, 3` represent the compensation iterations. This feature requires the user to change only one variable (`ISTEPS`), and then submit the same input file to continue the next iteration.

Many scratch files, including a file named `accltmp.tmp`, will be generated. *Do not delete them.* They are used to pass data between steps. A file, `compensation.info`, is generated and updated after each `ISTEPS` calculation. It contains iteration information, including maximum deviations in the x , y , and z directions. When the maximum deviation is within the tolerances specified in the `TOLX`, `TOLY`, and `TOLZ` fields, a message appears in the file indicating the compensation iterations have converged along with a message bootstrapping the next step. A file `spbk.new` is generated in the same directory and is used by the `*INCLUDE_COMPENSATION_BLANK_AFTER_SPRING BACK` keyword with the scale factor for the tool compensation set to one. After the compensation, a verification calculation may be needed.

```
*KEYWORD
*INTERFACE_COMPENSATION_3D_ACCELERATOR
$  ISTEPS      TOLX      TOLY      TOLZ      OPTION
   3         0.20      0.20      0.2         1
*INCLUDE_COMPENSATION_ORIGINAL_DYNAIN
```

```
./case20trimmed.dynain
*INCLUDE_COMPENSATION_SPRING BACK_INPUT
./spbk.dyn
*END
```

Currently, mesh coarsening and checking are not supported in the accelerated mode. Also, the dynain file from the previous die process is not necessary.

An example of this feature is shown for a simple channel type of draw (one-half model) in [Figure 26-33](#), which converged in three iterations; while four iterations were needed for the non-accelerated compensation.

Line Die Compensation:

The option MULTI_STEPS can be used together with *INCLUDE_COMPENSATION_-COMPENSATED_SHAPE_NEXT_STEP to enable compensation of tools for the next die process. An example is given below. In this example the target blank, named reference0.tmp, and the current tool named rigid.tmp come from the first die process. The disp.tmp file comes from the compensation in the second die process step. For example, a flanging die compensation can be a second die process step, preceded by a redraw die process as the first die process step.

Compensation of Trim Dies (Trim Die Nesting):

The trim die can be compensated using the drawn panel's springback shape when METHOD is set to -8. In the example below, which is also shown in [Figure 26-34](#), the draw panel, state1.k, is taken as the blank before springback, and draw panel springback shape, state2.k, is taken as the blank after springback. The tool shape for the draw process, drawtool.k, is used as the current tool. After the simulation, LS-DYNA will create a compensated tool named rigid.new, which can be used for the trim die shape.

Local Smoothing of Tooling Mesh:

The option LOCAL_SMOOTH can be used, along with a few more keywords, to smooth and restore the distorted tooling mesh after iterative compensation. In the example below, the keyword *INCLUDE_COMPENSATION_ORIGINAL_RIGID_TOOL includes an original tool, rigid.tmp, which has a good and smooth mesh. The keyword *INCLUDE_COMPENSATION_3D_RIGID_TOOL includes a compensated tool, rigidnew.bad, which could have a distorted mesh arising from the reasons listed when describing this option in the introduction section of this keyword.

The last keyword *SET_NODE_LIST_SMOOTH defines a node set that includes a distorted local area in the distorted mesh. Each node set defines a region needing smoothing. The node set should not include any boundary nodes of the tooling parts, otherwise position of the tooling may be altered. Smoothed tooling is stored in a file called rigid.new. In this example method 7 is active, the variable ELREF is set to 2, and PSID is left as undefined. Note also the *INCLUDE keyword is *not* supported here. For example, *SET_NODE_LIST_SMOOTH must not be in a separate file that is included in the main input file.

```

```

In an example shown in [Figures 26-35](#) and [26-36](#), smoothing of the local mesh is performed in the draw bead area of the NUMISHEET 2005 cross member. In this case the die gap is not maintained throughout the tooling surface. Typically, this happens in the draw bead regions when male beads have lower bending radii (missing upper radii) and female beads have only upper bending radii (missing lower radii). Two node sets are defined for local areas of left and right female draw beads ([Figure 26-37](#)), which needed smoothing. It is important to include in the node sets some of the nodes on the relatively flat portion of the binder immediately off the bend radii. The smoothed results are shown in [Figure 26-38](#).

In another example, a corner of a flanging die on a fender outer is being smoothed. The mesh becomes distorted after a few compensation iterations, as shown in [Figure 26-39](#). In [Figure 26-40](#), the result of local smoothing is shown, and the improvement is remarkable.

Compensation with Symmetric Boundary Condition:

A keyword example is provided in the manual pages related to [*INCLUDE_COMPENSATION](#).

Global Compensation Using the Original Tool Mesh:

For some tooling meshes, the compensated die surfaces will be distorted. The keyword option `*INCLUDE_COMPENSATION_ORIGINAL_TOOL` causes the compensation code to use the original tooling mesh (starting in the second compensation) to extrapolate the addendum and binder in the compensated tooling surfaces. This minimizes the accumulative error, compared with using the last compensated tooling mesh, and therefore is a preferred method.

A complete keyword example is included below. In it, part ID 3 (included in part set ID 1) is compensated after ITERATION 3 (ITER3), using method 8, with a scale factor of 0.5. The dynain files from the trimmed ITER3 is taken as the "BEFORE" state (see the `BEFORE_SPRINGBACK` option) and the dynain file from the springback calculation is taken as the "AFTER" state. The "DESIRED" blank shape is given by the dynain is from the trimmed ITER0 output. The "COMPENSATED_SHAPE" is taken from the `disp.tmp` file of the last compensation run. "CURRENT_TOOL" is also from last compensation iteration. The "ORIGINAL_TOOL", is taken from the tool mesh in ITER0. Updated trim curves `geotrm.new` are from the mapped trim lines of the last compensation.

It should be noted that, in an automatic compensation-loop calculation, as shown in the path of the input files, input files `disp.tmp`, `rigid.new`, and `geotrm.new`, which are the default file names of the previous compensation, should not be in the same directory as the current compensation run, as these files *will* be overwritten.

Updating Compensated Tool with Small Amount of Part Shape Change:

Often a part will have some small amount of shape change because of a product change. If the amount of shape change does not significantly alter the springback results, the compensated tools can be updated with the part mesh (inside the trim lines) or formed blank shape without going through another iterative compensation loop. This is accomplished using the `PART_CHANGE` option. Within the specified `MAXGAP`, the compensated tool shape can be updated. Changes to geometry involving sharp corners and transitions without fillets are not permissible. A complete keyword example is provided below, where a maximum gap of 5 mm is specified between the original shape and modified product shape. The updated part file name is `updatepart.tmp` and output file for the new rigid tool is `newrigid.k`.

```
*KEYWORD
*INTERFACE_COMPENSATION_3D_PART_CHANGE
$  MAXGAP

```

Option REFINE_RIGID: Tool Mesh Refinement for a Better Convergence:

The following keyword example refines the elements and aligns the nodes in the original tool mesh file `nominaltools.k` at provided trim curves `trimcurve106.k` defined using the keyword `*DEFINE_CURVE_TRIM_3D`. The refined rigid tool mesh will be output as `rigid_refined.tmp`, which can be used to start the iterative springback compensation process. The aligned nodes will also be output in a file named `bndnd0.tmp`.

```

*KEYWORD
*INTERFACE_COMPENSATION_3D_REFINE_RIGID
Nominaltools.k
trimcurve106.k
*END

```

Maintain Tangency:

To maintain tangency between the addendum and binder (Method 7) in the draw die and tangential transitions immediately off the rigid tool at the trim curve area to the addendum, the variable `TANGENT` must be set to "1". In the keyword example below, the `rigid_refined.tmp` (from the option `REFINE_RIGID`) is used as both the current and the original tool. The aligned nodes file `bndnd0.tmp` is included under `*INCLUDE_COMPENSATION_TRIM_NODE`, which is used for tangency calculation. Note the variable `TANGENT` replaces the keyword `*INCLUDE_COMPENSATION_TANGENT_CONSTRAINT`.

Option FLANGE: Compensation of Flanging Process:

This option is developed specifically to compensate flanging tools for springback in a flanging process. A maximum of two cards can be input. The following keyword example defines flanging steels with PIDs 6 and 4 moving in the directions defined by the vectors $[0.0, 0.0, -1.0]$ and $[0.0, -16.696, -5.674]$, respectively. The lower flanging post with PID2 is selected as the master tool surface mesh and the flanging steels are compensated while maintaining the necessary tool gaps as in the original tool mesh `iter0tools.k`. Note in the compensation of flanging process the requirement on the even tool gap everywhere is removed, so flanging steels do not have to follow the flanging post, for example in the flanging steel radius area, etc.

| Default | none | | | | | | | |

Optional Card.

| | | | | | | | | |
|----------|--------|---|---|---|---|---|---|---|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | Format | | | | | | | |
| Type | 1 | | | | | | | |
| Default | 2 | | | | | | | |

VARIABLE

DESCRIPTION

- | | |
|--------|---|
| FNAME | Name of the file where the component data will be written |
| FORMAT | File format to use: EQ.1: Use old binary file format EQ.2: Use new LSDA file format |

Remarks:

If Z = is used on the command line, this card will be ignored. If this card is in effect, the new LSDA file format is the default format to be used. The new format has certain advantages, and one possible drawback:

1. It allows for the use of the TITLE modifier on all *INTERFACE_COMPONENT inputs, so that subsequent *INTERFACE_LINKING cards can refer to components by a user specified ID.

2. It is fully portable between machines with different precision and byte order.
3. It maintains the full precision of the coordinate vector. The internal coordinate vector has been in double precision for quite some time, even for single precision executables. The old binary format writes 32 bit data for single precision executables, losing some precision in the process.
4. Because of the maintained precision, the new format files will be significantly larger when running in single precision.

Of course, the new file format cannot be used for subsequent analysis with older versions of LS-DYNA, particularly those with a Product ID less than 50845. Executables which can read the new format for *INTERFACE_LINKING analysis will automatically detect whether the new or old format is in use.

***INTERFACE_COMPONENT_OPTION1_{OPTION2}**

Available values for OPTION1 include:

- NODE
- SEGMENT

OPTION2 only allows the value:

- TITLE

Purpose: Create an interface for use in subsequent linking calculations. This command applies to the first analysis for storing interfaces in the interface file specified either by "Z=isf1" on the execution line or by the *INTERFACE_COMPONENT_FILE command. The output interval used to write data to the interface file is controlled by OPIFS on *CONTROL_OUTPUT. If OPIFS is not specified, the interval defaults to 1/10th the value of DT specified in *DATABASE_BINARY_D3PLOT.

This capability allows the definition of interfaces that isolate critical components. A database is created that records the motion of the interfaces. In later calculations the isolated components can be reanalyzed with arbitrarily refined meshes with the motion of their boundaries specified by the database created by this input. The interfaces defined here become the masters in the tied interface options.

Each definition consists of a set of cards that define the interface. Interfaces may consists of a set of segments for later use with *INTERFACE_LINKING_SEGMENT, an ordered line of nodes for use with *INTERFACE_LINKING_EDGE, or an unordered set of nodes for use with *INTERFACE_LINKING_NODE.

Title Card. Additional card for TITLE keyword option.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|---|---|---|---|---|---|
| Variable | ID | Title | | | | | | |
| Type | I | A70 | | | | | | |
| Default | none | None | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| ID | ID for this interface in the linking file |
| Title | Title for this interface |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|---|---|---|---|---|
| Variable | SID | CID | NID | | | | | |
| Type | I | I | I | | | | | |

VARIABLE**DESCRIPTION**

| | |
|-----|--|
| SID | Set ID, see *SET_NODE or *SET_SEGMENT. |
| CID | Coordinate system ID |
| NID | Node ID |

Remarks:

CID and NID are optional. If CID appears, the transformation matrix for this coordinate system is written to the linking file at each output state. If NID appears, the displacement of this node is also written to the file. This information is then available to be used by the *INTEFACE_LINKING_NODE_LOCAL. If either of these is non-zero, then the linking file will be written in the LSDA format, as the old format cannot support this optional output.

If the old style binary format is used for the linking file (see *INTERFACE_COMPONENT_FILE) then the ID values are ignored and all components are numbered according to their input order, starting from 1.

***INTERFACE_DE_HBOND**

Purpose: Define the failure models for bonds linking various discrete element (DE) parts within one heterogeneous bond (*DEFINE_DE_HBOND).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | IID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

Bond Definition Cards. For each bond definition, include an additional card. This input ends at the next keyword (“*”) card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|--------|--------|-------|------|------|-----|
| Variable | PID1 | PID2 | PTYPE1 | PTYPE2 | FRMDL | FRGK | FRGS | DMG |
| Type | I | I | I | I | I | F | F | F |
| Default | none | none | none | none | 1 | none | none | 1.0 |

VARIABLE

DESCRIPTION

| | |
|------|---|
| IID | Interface ID. All interfaces should have a unique ID |
| PID1 | First part ID. |
| PID2 | Second part ID. PID1 and PID2 define the bonds that this fracture model is applied to. There are three combinations as Case a: PID1.EQ.0 This is the default model for all bonds, overriding the default model defined in Card 1.1 of *DEFINE_DE_HBOND. Case b: PID1.GT.0 and PID2.EQ.0 This model is applied to the bonds within part PID1, instead of the default model. Case c: PID1.GT.0 and PID2.GT.0 |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | <p>This model is applied to the bonds between parts PID1 and PID2 only, but not to those within part PID1 or part PID2 (as in case b).</p> <p>Notes:</p> <ol style="list-style-type: none">1. The default fracture model is applied to all parts that are not specified in case b.2. The fracture model of the part with a smaller part id is applied to the bonds between two different parts if not specified in case c. |
| PTYPE1 | First part type: EQ.0: DES part set EQ.1: DES part |
| PTYPE2 | Second part type: EQ.0: DES part set EQ.1: DES part |
| FRMDL | Fracture model. (same as FRMDL in Card 1.1 of keyword *DEFINE_DE_HBOND.) |
| FRGK | Fracture energy release rate for volumetric deformation. (same as FRGK in Card 1.1 of keyword *DEFINE_DE_HBOND.) |
| FRGS | Fracture energy release rate for shear deformation. (same as FRGS in Card 1.1 of keyword *DEFINE_DE_HBOND.) |
| DMG | Continuous damage development. (same as DMG in Card 1.1 of keyword *DEFINE_DE_HBOND.) |

*INTERFACE

*INTERFACE_LINKING_DISCRETE_NODE

*INTERFACE_LINKING_DISCRETE_NODE_OPTION

Available options include:

NODE

SET

Purpose: Link node(s) to an interface in an existing interface file. This link applies to all element types. The interface file is specified using *INTERFACE_LINKING_FILE or by including "L=**filename**" on the execution line.

With this command, nodes in a node set must be given in the same order as they appear in the interface file. This restriction does not apply to the more recent keyword *INTERFACE_LINKING_NODE_....

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|------|---|---|---|---|---|---|
| Variable | NID/NSID | IFID | | | | | | |
| Type | I | I | | | | | | |

VARIABLE

DESCRIPTION

| | |
|------|---|
| NID | Node ID or Node set ID to be moved by interface file, see *NODE or *SET_NODE. |
| IFID | Interface ID in interface file. |

***INTERFACE_LINKING_EDGE**

Purpose: Link a series of nodes to an interface in an existing interface force file. The interface file is specified using *INTERFACE_LINKING_FILE or by including "L=filename" on the execution line.

| | | | | | | | | |
|----------|------|------|---|---|---|---|---|---|
| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | NSID | IFID | | | | | | |
| Type | I | I | | | | | | |

| <u>VARIABLE</u> | <u>DESCRIPTION</u> |
|-----------------|--|
| NSID | Node set ID to be moved by interface file. |
| IFID | Interface ID in interface file. |

Remarks:

The set of nodes defined will be constrained to follow the movement of the interface IFID, which should correspond to a curve output on a previous analysis via *INTERFACE_COMPONENT_NODE. The order of the nodes in the first analysis is important. The nodes, in the order specified in the first analysis, represent a curve. Each node in set NSID will be tied to the point on the curve nearest to its initial position, and then will be constrained to follow that point on the curve for the duration of the analysis. This option is intended to be used with beam or shell elements, as both translational and rotational degrees of freedom are constrained.

*INTERFACE

*INTERFACE_LINKING_FILE

*INTERFACE_LINKING_FILE

Purpose: Allow for the specification of the file from which the component interface data should be read.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|---|---|---|---|---|---|---|
| Variable | Filename | | | | | | | |
| Type | A80 | | | | | | | |
| Default | none | | | | | | | |

VARIABLE

DESCRIPTION

FNAME

Name of the file from which the component data will be read

Remarks:

If L= is used on the command line, this card will be ignored. There is no option to specify the file format, as the file format is automatically detected.

***INTERFACE_LINKING_NODE_OPTION**

Available options include:

SET

LOCAL

SET_LOCAL

Purpose: Link nodes(s) to an interface in an existing interface file. This link applies to all element types. The interface file is specified using ***INTERFACE_LINKING_FILE** or by including "**L=filename**" on the execution line.

Node/Set ID Card. Include as many cards as desired. Input ends at the next keyword ("******") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|------|----|----|----|---|---|---|
| Variable | NID/NSID | IFID | FX | FY | FZ | | | |
| Type | I | I | I | I | I | | | |

VARIABLE**DESCRIPTION**

| | |
|------|---|
| NID | Node ID or Node set ID to be moved by interface file. See *NODE or *SET_NODE . |
| IFID | Interface ID in interface file. |
| FX | The ID of a *DEFINE_FUNCTION which determines the <i>x</i> direction displacement scale factor. See Remarks. |
| FY | The ID of a *DEFINE_FUNCTION which determines the <i>y</i> direction displacement scale factor. See Remarks. |
| FZ | The ID of a *DEFINE_FUNCTION which determines the <i>z</i> direction displacement scale factor. See Remarks. |

Card 2. This card appears after Card 1 when the `_LOCAL` option is used.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|---|---|---|---|
| Variable | LCID | LNID | USEC | USEN | | | | |
| Type | I | I | I | I | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| LCID | Local coordinate system ID for transforming displacements. |
| LNID | Local node ID for transforming displacements |
| USEC | Flag to indicate the use of the coordinate system in the linking file during displacement transformation. See Remarks. EQ.0: Linking file coordinate system is ignored. EQ.1: Linking file coordinate system is used. |
| USEN | Flag to indicate the use of the node displacement in the linking file during displacement transformation. See Remarks. EQ.0: Node displacement is not used. EQ.1: Node displacement is used. |

Remarks:

The set of nodes is constrained to follow the displacement of the interface having ID IFID in the linking file. Note that the linking file is usually generated by the `*INTERFACE_COMPONENT_NODE` keyword in a previous analysis.

The order of the nodes is not important. Each node in set NID will be tied to the nearest node in IFID using a bucket sort during the initialization phase. Nodes not found are reported and subsequently not constrained. Translational degrees of freedom are constrained. If the constrained analysis has rotational degrees of freedom, then the rotation degrees of freedom will be likewise constrained and the linking file *must* include rotational degrees of freedom.

The displacements in the linking file can be scaled upon input so that

$$\mathbf{u}_{\text{constrained}} = \begin{bmatrix} f_{\text{FX}}(\dots) & 0 & 0 \\ 0 & f_{\text{FY}}(\dots) & 0 \\ 0 & 0 & f_{\text{FZ}}(\dots) \end{bmatrix} \mathbf{u}_{\text{linking file}}$$

where $f_{FX}(\dots)$ is the *DEFINE_FUNCTION function having ID FX and so on. When a scaling function is not specified, the corresponding component is imported unscaled as if the scaling function had a constant value of unity. These functions may take either 0, 1, 3, or 4 input arguments. The functions FX, FY, and FZ may be different and they may take different numbers of arguments. The data passed into the scaling function depends on the number of arguments that the function takes and the possibilities can be broken down into four cases:

1. *0 variables.* A function taking no inputs is constant over space and time. LS-DYNA evaluates such a function at the start of the calculation and uses that value for the duration of the run.
2. *1 variables.* LS-DYNA passes in the simulation time at each step and the resulting value is applied to all nodes in the set.
3. *3 variables.* LS-DYNA passes in the *initial position* of each constrained node as an (x, y, z) triple at the start of the calculation and then uses the result for the duration of the run.
4. *4 variables.* LS-DYNA passes in the *current* simulation time and the *initial position* of each of the constrained nodes as an (x, y, z, t) tuple. This function is updated at each time step. Using scaling functions of 4 variables may result in a performance penalty as each function must be evaluated for every slave node every cycle.

If time dependent scaling functions are used, then the constrained nodes must start with coordinates identical to the constraining nodes in the linking file.

The LOCAL option and the values of the LCID, LNID, USEC, USEN flags, which was designed in conjunction with Honda R&D Co., Ltd., allow for the interface displacements to be transformed in various ways. By default, the scale factors FX, FY, and FZ act on the nodal displacements in the global coordinate system of the constrained calculation. This may be undesirable depending on how the global coordinate system of the linked calculation is defined. The most general transformation rule is:

$$\mathbf{u}_{\text{constrained}} = \mathbf{Q}_2 \begin{bmatrix} f_{FX}(\dots) & 0 & 0 \\ 0 & f_{FY}(\dots) & 0 \\ 0 & 0 & f_{FZ}(\dots) \end{bmatrix} \mathbf{Q}_1 (\mathbf{u}_{\text{linked}} - \mathbf{c}_1) - \mathbf{c}_2$$

where,

\mathbf{c}_1 = The displacement of the NID node in the linking file

\mathbf{c}_2 = The displacement of node LNID

\mathbf{Q}_1 = Rotation into the local coordinates of the linking file

\mathbf{Q}_2 = Rotation into the local coordinate system; if unset the inverse of \mathbf{Q}_1

***INTERFACE**

***INTERFACE_LINKING_NODE**

If USEC = 0, then \mathbf{Q}_1 is the identity rotation and any coordinate system in the linking file is ignored. If USEN = 0, then \mathbf{c}_1 is set to $\mathbf{0}$ and NID in the linking file is ignored.

***INTERFACE_LINKING_SEGMENT**

Purpose: Link segments to an interface in an existing interface file. The interface file is specified using *INTERFACE_LINKING_FILE or by including "L=filename" on the execution line.

Segment Set ID Card. Include as many cards as desired. Input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|---|---|---|---|---|---|
| Variable | SSID | IFID | | | | | | |
| Type | I | I | | | | | | |

| <u>VARIABLE</u> | <u>DESCRIPTION</u> |
|-----------------|--------------------|
|-----------------|--------------------|

| | |
|------|--|
| SSID | Segment set to be moved by interface file. |
|------|--|

| | |
|------|---------------------------------|
| IFID | Interface ID in interface file. |
|------|---------------------------------|

Remarks:

The set of segments defined will be constrained to follow the movement of the interface IFID, which should correspond to an interface output on a previous analysis using the *INTERFACE_COMPONENT_SEGMENT keyword. The behavior will be the same as if set SSID is the slave side of a *CONTACT_TIED_SURFACE_TO_SURFACE with IFID as the master. Translational movement will be constrained, but not rotations.

***INTERFACE_SPRINGBACK_OPTION1_{OPTION2}**

Available options included for *OPTION1* are:

LSDYNA

NASTRAN

SEAMLESS

EXCLUDE (See [Remark 8.](#))

and for *OPTION2*:

<BLANK>

THICKNESS

NOTHICKNESS (See [Remark 1.](#))

Purpose: This keyword causes LS-DYNA to, upon termination, write the final state of the system to an output file so that the results can be used as input for other subsequent calculations, such as trimming, springback, flanging, and hemming. In addition to the forming results the output can optionally contain additional nodal constraints. The keyword name, which contains SPRINGBACK, is due to historical reasons. All the options, except SEAMLESS, are used to control the output of the forming information.

With the SEAMLESS option, LS-DYNA will automatically run the springback analysis after the termination time of the explicit or implicit dynamic analysis. See [Remarks for Seamless Springback](#) for more details.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

Node Cards. Define a list of nodal points and constraints. For the SEAMLESS Option the constraints are used for the springback analysis. This input ends at the next keyword ("*") card.

| | | | | | | | | |
|----------|-----|----|----|---|---|---|---|---|
| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | NID | TC | RC | | | | | |
| Type | I | F | F | | | | | |

VARIABLE

DESCRIPTION

PSID

Part set ID. See *SET_PART.

NSHV

Number of shell or solid history variables (beyond the six stresses and effective plastic strain) to be initialized in the interface file.

For solids, one additional state variable (initial volume) is also written. If NSHV is nonzero, the element formulations, unit system, and constitutive models should not change between runs.

If NHSV exceeds the number of integration point history variables required by the constitutive model, only the number required is written; therefore, if in doubt, set NHSV to a large number, such as 100.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| FTYPE | File type: (See Remark 5) EQ.0: ASCII, EQ.1: binary EQ.2: both ASCII and binary. EQ.3: LSDA format (for LSDYNA option only) EQ.10: ASCII large format (see *INITIAL_STRESS_SHELL) EQ.11: binary large format EQ.12: both ASCII and binary large format |
| FTENSR | Flag for dumping tensor data from the element history variables into the dynain file. EQ.0: Don't dump tensor data from element history variables EQ.1: Dump any tensor data from element history variables into the dynain file in GLOBAL coordinate system. Currently, only Material 190 supports this option. |
| NTHHSV | Number of thermal history variables. |
| INTSTRN | Output of strains for shells; see also *INITIAL_STRAIN_SHELL. EQ.0: Only at the innermost and outermost integration points, EQ.1: At all through-thickness integration points. |
| SLDO | Output of solid element data as EQ.0: *ELEMENT_SOLID, or EQ.1: *ELEMENT_SOLID_ORTHO. |
| NCYC | Number of process cycles this simulation corresponds to in the simulation of wear processes; see Remark 6 . |
| FSPLIT | Flag for splitting of the dynain file (only for ASCII format). EQ.0: dynain file written in one piece. EQ.1: Output is divided into two files: dynain_geo including the geometry data and dynain_ini including initial stresses and strains. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| NDFLAG | Flag to dump nodes into dynain file. EQ.0: default, dump only SPH and element nodes EQ.1: dump all nodes |
| CFLAG | Output contact state. EQ.0: default, do not output EQ.1: output contact state, currently only Mortar segment pair information, see Remark 7 . |
| NID | Node ID, see *NODE. |
| TC | Translational Constraint: EQ.0: no constraints, EQ.1: constrained x displacement, EQ.2: constrained y displacement, EQ.3: constrained z displacement, EQ.4: constrained x and y displacements, EQ.5: constrained y and z displacements, EQ.6: constrained z and x displacements. EQ.7: constrained x , y , and z displacements. |
| RC | Rotational constraint: EQ.0: no constraints, EQ.1: constrained x rotation, EQ.2: constrained y rotation, EQ.3: constrained z rotation, EQ.4: constrained x and y rotations, EQ.5: constrained y and z rotations, EQ.6: constrained z and x rotations, EQ.7: constrained x , y , and z rotations. |

Remarks:

1. **NOTHICKNESS Option.** The NOTHICKNESS option is available when the keyword's first option is either LSDYNA or NASTRAN. With the NOTHICKNESS option the shell element thickness is not output.
2. **Filenames.** The file name for the LSDYNA option is dynain and for NASTRAN is nastin.
3. **Trimming.** Trimming is available for the adaptive mesh, but it requires manual intervention. To trim an adaptive mesh, use the following procedure:
 - a) Generate the file, dynain, using the keyword *INTERFACE_SPRINGBACK_LSDYNA.
 - b) Prepare a new input deck including the dynain file.
 - c) Add the keyword *ELEMENT_TRIM to this new deck.
 - d) Add the keyword *DEFINE_CURVE_TRIM to this new deck.
 - e) Run this new input deck with **i=input_file_name**. The adaptive constraints are eliminated by remeshing and the trimming is performed.
 - f) In case this new trimmed mesh is needed, run a zero termination time job and output the file generated using the keyword, *INTERFACE_SPRINGBACK_LSDYNA.
4. **Temperature.** The file new_temp_ic.inc will be created for a thermal solution and a coupled thermal-mechanical solution. The file new_temp_ic.inc is a KEYWORD include file containing *new temperature initial conditions* for the nodes belonging to the PSID.
 - a) For thermal user materials it is possible to dump thermal history variables. See the NTHHSV field.
5. **FTYPE.** The choice of format size in field FTYPE is only available for shell stresses and shell history data; see parameter LARGE on *INITIAL_STRESS_SHELL. For solid and beam elements, always the large format is written to dynain; that is LARGE is automatically set to 1 on *INITIAL_STRESS_SOLID and *INITIAL_STRESS_BEAM, respectively.
6. **NCYC.** When simulating wear processes, this represents the number of process cycles this particular simulation corresponds to and *INITIAL_CONTACT_WEAR cards are generated accordingly in the dynain file (only ASCII format supported). Cards will only be generated for nodes in contact interfaces associated with a *CONTACT_ADD_WEAR, and having SPR or MPR set to 2 on

the first card on *CONTACT. This wear data is in a subsequent simulation accounted for NCYC times when modifying the worn geometry, or alternatively processed in LS-PrePost.

7. **CFLAG.** Transferring contact state may be important, in particular tied information. Setting this parameter to 1 will output Mortar contact segment pairs for sliding, tied, tiebreak and tied weld options. The resulting dynain.lsd, which has to be using LSDA format (FTYPE=3), can be included in subsequent simulation to restore the contact state. The LS-DYNA version or core count used may be changed between simulations, and also the contact type (for instance changing from tied weld to simple tied), if only the contact ID and node IDs making up the segments remain unchanged. If parts or elements are removed between simulations, and these happen to contain segments that are in the dynain.lsd file these pairs will be simply ignored. This provides a flexibility that is appealing in multistage processes as is common in the simulation industry. For sliding contact, typically the ignore and friction state is transferred.
8. **EXCLUDE.** This option is used to limit what data will be output to the LSDYNA dynain file. The input format is completely different, and consists of any number of keyword cards WITHOUT the leading *. These cards and their associated data will not be output. For example:

```
*INTERFACE_SPRINGBACK_EXCLUDE  
BOUNDARY_SPC_NODE  
CONSTRAINED_ADAPTIVITY
```

would output all the normal dynain data, except for the SPC and adaptive constraints. The currently recognized keywords that can be excluded are:

```
BOUNDARY_SLIDING_PLANE  
BOUNDARY_SPC_NODE  
CONSTRAINED_ADAPTIVITY  
DEFINE_COORDINATE_NODES  
DEFINE_COORDINATE_VECTOR  
ELEMENT_BEAM  
ELEMENT_SHELL  
ELEMENT_SOLID  
INITIAL_STRAIN_SHELL  
INITIAL_STRAIN_SOLID  
INITIAL_STRESS_BEAM  
INITIAL_STRESS_SHELL  
INITIAL_STRESS_SOLID  
INITIAL_TEMPERATURE_NODE  
INITIAL_VELOCITY_NODE
```

NODE
REFERENCE_GEOMETRY

Remarks for Seamless Springback:

When seamless springback is invoked, the solution automatically and seamlessly switches from explicit or implicit dynamic to implicit static mode at the termination time and continues to run the static springback analysis. Seamless springback can be activated in the original LS-DYNA input deck or later using a small restart input deck. In this way, the user can decide to continue a previous analysis by restarting to add the implicit springback phase. (Another alternative approach to springback simulation is to use the keyword `*INTERFACE_SPRINGBACK_LSDYNA` to generate a dynain file after forming, and then perform a second simulation running LS-DYNA in fully implicit mode for springback. See Appendix P for a description of how to run an implicit analysis using LS-DYNA.)

The implicit springback phase begins when the forming simulation termination time `ENDTIM` is reached, as specified with the keyword `*CONTROL_TERMINATION`. Since the springback phase is static, its termination time can be chosen arbitrarily (unless material rate effects are included). The default choice is $2.0 \times \text{ENDTIM}$, and can be changed using the `*CONTROL_IMPLICIT_GENERAL` keyword; see fields `DT0` and `NSBS`.

Since the springback analysis is a static simulation, a minimum number of essential boundary conditions or Single Point Constraints (SPC's) can be input to prohibit rigid body motion of the part. These boundary conditions can be added for the springback phase using the input option on the `*INTERFACE_SPRINGBACK_SEAMLESS` keyword above.

If no boundary conditions are added with the `SEAMLESS` option, an eigenvalue computation is automatically performed using the Inertia Relief Option to find any rigid body modes and then automatically constrain them out of the springback simulation (see `*CONTROL_IMPLICIT_INERTIA_RELIEF`). This approach introduces no artificial deformation and is recommended for many simulations.

An "SPR" option is available for several `*CONTROL_IMPLICIT` keywords to further control the implicit springback phase. Generally, default settings can be used, in which case the SPR option for `*CONTROL_IMPLICIT` keywords is not necessary.

To obtain accurate springback solutions, a nonlinear springback analysis must be performed. In many simulations, this iterative equilibrium search will converge without difficulty. If the springback simulation is particularly difficult, either due to nonlinear deformation, nonlinear material response, or numerical precision errors, a multi-step springback simulation will be automatically invoked. In this approach, the springback deformation is divided into several smaller, more manageable steps.

Two specialized features in LS-DYNA are used to perform multi-step springback analyses. The addition and gradual removal of artificial springs is performed by the artificial stabilization feature. Simultaneously, the automatic time step control is used to guide the solution to the termination time as quickly as possible, and to persistently retry steps where the equilibrium search has failed. By default, both of these features are active during a seamless springback simulation. However, the default method attempts to solve the springback problem in a single step. If this is successful, the solution will terminate normally. If the single step springback analysis fails to converge, the step size will be reduced, and artificial stabilization will become active. Defaults for these features can be changed using the following keywords:

- *CONTROL_IMPLICIT_GENERAL,
- *CONTROL_IMPLICIT_AUTO, and
- *CONTROL_IMPLICIT_STABILIZATION.

***INTERFACE_SSI_{OPTION}_ID**

Purpose: This card creates a tied-contact soil-structure interface for use in a transient analysis of a soil-structure system subjected to earthquake excitation. This card allows the analysis to start from a static state of the structure, as well as to read in ground motions recorded on the interface in an earlier analysis.

Available options are:

<BLANK>

OFFSET

CONSTRAINED_OFFSET

LS-DYNA implements the effective seismic input method [Bielak and Christiano (1984)] for modeling the interaction of a non-linear structure with a linear soil foundation subjected to earthquake excitation. Note that any non-linear portion of the soil near the structure may be incorporated with the structure into a larger generalized structure, but the soil is assumed to behave linearly beyond a certain distance from the structure.

The effective seismic input method couples the dynamic scattered motion in the soil, which is the difference between the motion in the presence of the structure and the free-field motion in its absence, with the total motion of the structure. This replaces the distant earthquake source with equivalent effective forces adjacent to the soil-structure interface and allows truncation of the large soil domain using a non-reflecting boundary (e.g. *MAT_PML_ELASTIC) to avoid unnecessary computation. These effective forces can be computed using the free-field ground motion at the soil-structure interface, thus avoiding deconvolution of the free-field motion down to depth.

Non-linear behavior of the structure may be modeled by first carrying out a static analysis of the soil-structure system, and then carrying out the transient analysis with only the structure initialized to its static state. Because the transient analysis employs the dynamic scattered motion in the soil, the soil cannot have any static loads only if only the structure is subjected to static forces. Consequently, the structure must be supported by the static reactions at the soil-structure interface. Additionally, the soil nodes at the interface must be initialized to be compatible with the initial static displacement of the structure. LS-DYNA will do these automatically if the soil-structure interface is identified appropriately in the static analysis and reproduced in the transient analysis.

Thus, soil-structure interaction analysis under earthquake excitation may be carried out in LS-DYNA as follows:

1. Carry out a static analysis of the soil-structure system (e.g. using dynamic relaxation; see *CONTROL_DYNAMIC_RELAXATION), with the soil-structure interface identified using *INTERFACE_SSI_STATIC_ID

Optionally, carry out a free-field analysis to record free-field motions on the future soil-structure interface, using either *INTERFACE_SSI_AUX or *INTERFACE_SSI_AUX_EMBEDDED, for surface-supported or embedded structures respectively.

2. Carry out the transient analysis as a full-deck restart job (see *RESTART), with only the structure initialized to its static stress state (see *STRESS_INITIALIZATION), and the same soil-structure interface identified using *INTERFACE_SSI_ID with the same ID as in static analysis:
 - a) The structure mesh must be identical to the one used for static analysis.
 - b) The soil mesh is expected to be different from the one used for static analysis, especially because non-reflecting boundary models may be used for transient analysis.
 - c) The meshes for the structure and the soil need not match at the interface.
 - d) Only the structure must be subjected to static loads, via *LOAD_BODY_PARTS
 - e) The earthquake ground motion is specified using *LOAD_SEISMIC_SSI, and/or read from motions recorded from a previous analysis using *INTERFACE_SSI_AUX or *INTERFACE_SSI_AUX_EMBEDDED.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|---------|---|---|---|---|---|---|

| Variable | GMSET | SF | BIRTH | DEATH | MEMGM | | | |
| Type | I | F | F | F | I | | | |
| Default | none | 1. | 0. | 10 ²⁸ | 2500000 | | | |

VARIABLE**DESCRIPTION**

| | |
|---------|--|
| ID | Soil-structure interface ID. This is required and must be unique amongst all the contact interface IDs in the model. |
| HEADING | A descriptor for the given ID. |
| STRID | Segment set ID of base of structure at soil-structure interface. |
| SOILID | Segment set ID of soil at soil-structure interface. |
| SPR | Include the slave side in the *DATABASE_NCFORC and the *DATABASE_BINARY_INTFOR interface force files: EQ.1: slave side forces included. |
| MPR | Include the master side in the *DATABASE_NCFORC and the *DATABASE_BINARY_INTFOR interface force files: EQ.1: master side forces included. |
| GMSET | Identifier for set of recorded motions from *INTERFACE_SSI_AUX or *INTERFACE_SSI_AUX_EMBEDDED |
| SF | Recorded motion scale factor. |
| BIRTH | Time at which specified recorded motion is activated. |
| DEATH | Time at which specified recorded motion is removed: EQ.0.0: default set to 10 ²⁸ |
| MEMGM | Size in words of buffer allocated to read in recorded motions |

Remarks:

1. **Tied Contact Interface.** A tied contact interface (*CONTACT_TIED_SURFACE_TO_SURFACE) is created between the structure and the soil using the specified segment sets, with the soil segment set as the master segment set and the structure segment set as the slave. Naturally, the two segment sets should not have merged nodes and can be non-matching in general. However, the area covered by the two surfaces should match.
2. **Keyword Options.** The options OFFSET and CONSTRAINED_OFFSET create the corresponding tied surface-to-surface contact interface.
3. **Interface ID.** The soil-structure interface ID is assigned as the ID of the generated contact interface.
4. **Soil Segment Set Orientation.** It is assumed that the soil segment set is oriented toward the structure.
5. **Multiple Soil-Structure Interfaces.** Multiple soil-structure interfaces are allowed, such as for bridge analysis.
6. **Reading Recorded Motions.** The recorded motions are read in from a binary file named gmbin by default, but a different filename may be chosen using the option GMINP on the command line (see Getting Started, Execution Syntax).
7. **Recorded Motions.** If the motions from *INTERFACE_SSI_AUX or *INTERFACE_SSI_AUX_EMBEDDED were recorded on a segment set, then the free-field motions on each node in the master segment set of the soil-structure interface are calculated from the nearest segment of the segment set used to record the motions.

If, however, the motions were recorded on a node set, then the motions on the master segment set nodes is found by interpolation as is done for *LOAD_SEISMIC_SSI.

***INTERFACE_SSI_AUX_{OPTION}**

Available options are:

<BLANK>

NODE

Purpose: This card records the motion at a free surface, or on a set of nodes on a free surface, for the purpose of using the recorded motion as a free-field motion in a subsequent interaction analysis using *INTERFACE_SSI. By default, this card records motions on a segment set defining a surface, but can record motions on a node set using the option NODE. Only one of *INTERFACE_SSI_AUX and *INTERFACE_SSI_AUX_EMBEDDED is to be used for a particular soil-structure interface.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|---|---|---|---|---|---|
| Variable | GMSET | SETID | | | | | | |
| Type | I | I | | | | | | |
| Default | none | none | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|-------|--|
| GMSET | Identifier for this set of recorded motions to be referred to in *INTERFACE_SSI. Must be unique. |
| SETID | Segment set or node set ID where motions are to be recorded. |

Remarks:

1. **Output File.** The motions on the specified segment set or node set is recorded in a binary file named `gmbin` by default, but a different filename may be chosen using option `GMOUT` on the command line (see Getting Started, Execution Syntax).
2. **Output Interval.** The output interval for the motions may be specified using the parameter `GMDT` on the *CONTROL_OUTPUT card, with the default value being one tenth of the output interval for `d3plot` states.

***INTERFACE_SSI_AUX_EMBEDDED_{OPTION1}_{OPTION2}**

Purpose: This card creates a tied-contact interface and records the motions and contact forces. The recorded data can then be used as free-field motion and reactions in a subsequent soil-structure interaction analysis using *INTERFACE_SSI, where the structure is embedded in the soil after part of the soil has been excavated. Only one of *INTERFACE_SSI_AUX and *INTERFACE_SSI_AUX_EMBEDDED is to be used for a particular soil-structure interface.

Available options for *OPTION1* are:

<BLANK>

OFFSET

CONSTRAINED_OFFSET

OPTION2 allows an optional ID to be given:

ID

ID Card. Additional card for ID keyword option.

| | | | | | | | | |
|----------|----|---------|---|---|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | ID | HEADING | | | | | | |

| | | | | | | | | |
|----------|-------|-------|--------|-----|-----|---|---|---|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | GMSET | STRID | SOILID | SPR | MPR | | | |
| Type | I | I | I | I | I | | | |
| Default | none | none | none | 0 | 0 | | | |

VARIABLE

DESCRIPTION

ID

Soil-structure interface ID. This is required and must be unique amongst all the contact interface IDs in the model.

HEADING

A descriptor for the given ID.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| GMSET | Identifier for this set of recorded motions to be referred to in *INTERFACE_SSI. Must be unique. |
| STRID | Segment set ID at base of soil to be excavated. |
| SOILID | Segment set ID at face of rest of the soil domain. |
| SPR | Include the slave side in the *DATABASE_NCFORC and the *DATABASE_BINARY_INTFOR interface force files: EQ.1: slave side forces included. |
| MPR | Include the master side in the *DATABASE_NCFORC and the *DATABASE_BINARY_INTFOR interface force files: EQ.1: master side forces included. |

Remarks:

1. **Output Binary File.** The motions on the specified segment set or node set is recorded in a binary file named gmbin by default, but a different filename may be chosen using the option GMOUT on the command line (see Getting Started, Execution Syntax).
2. **Output Interval.** The output interval for the motions may be specified using the parameter GMDT on the *CONTROL_OUTPUT card, with the default value being one tenth of the output interval for d3plot states.

***INTERFACE_SSI_STATIC_{OPTION}_ID**

Purpose: This card creates a tied-contact soil-structure interface in order to record the static reactions at the base of the structure, which are to be used in a subsequent dynamic analysis of the soil-structure system subjected to earthquake excitation. This card is intended to be used with the initial static analysis of the structure subjected to gravity loads.

Available options are:

<BLANK>

OFFSET

CONSTRAINED_OFFSET

| | | | | | | | | |
|----------|----|---------|---|---|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| ID | Soil-structure interface ID. This is required and must be unique amongst all the contact interface IDs in the model. |
| HEADING | A descriptor for the given ID. |
| STRID | Segment set ID of base of structure at soil-structure interface. |
| SOILID | Segment set ID of soil at soil-structure interface. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| SPR | Include the slave side in the *DATABASE_NCFORC and the *DATABASE_BINARY_INTFOR interface force files: EQ.1: slave side forces included. |
| MPR | Include the master side in the *DATABASE_NCFORC and the *DATABASE_BINARY_INTFOR interface force files: EQ.1: master side forces included. |

Remarks:

See *INTERFACE_SSI_ID. The ID used for a particular interface in the static analysis must also be used for the same interface identified using *INTERFACE_SSI_ID during dynamic analysis.

***INTERFACE_THICKNESS_CHANGE_COMPENSATION**

Purpose: This keyword changes the uniform gap between an upper and lower tool, to a variable gap according to the varied, non-homogeneous thickness of a sheet blank from a forming simulation. This keyword must be used together with *INCLUDE_COMPENSATION_CURRENT_TOOLS, and, *INCLUDE_COMPENSATION_BEFORE_COMPESNATION. This is useful in hot stamping simulation, where contacts are required between the upper/lower tools and the sheet blank to ensure the proper cooling rate.

Compensation Card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|---|---|---|---|---|---|
| Variable | IFLG | THK0 | | | | | | |
| Type | I | F | | | | | | |
| Default | none | none | | | | | | |

Current Tool Definition Card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----------|---|---|---|---|---|---|---|
| Variable | FILENAME1 | | | | | | | |
| Type | A80 | | | | | | | |
| Default | none | | | | | | | |

Formed Blank Definition Card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----------|---|---|---|---|---|---|---|
| Variable | FILENAME2 | | | | | | | |
| Type | A80 | | | | | | | |
| Default | none | | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| IFLG | Activation flag; set to "1" to invoke the option. |
| THK0 | Initial thickness of the sheet blank. |
| FILENAME1 | The file name for the rigid tools. This file usually includes a set of upper and lower tools, with proper, uniform gap between them. |
| FILENAME2 | The file name of a dyanin file. This file results from a forming simulation, which includes the thickness on the sheet blank, as in *ELEMENT_SHELL_THICKNESS. |

Remarks:

A keyword example is provided below. The file name for the current tool set is rigid.inc, which will be changed from a uniform gap of 1.2mm to a non-homogeneous gap according to the sheet blank thickness from the file drawn.dynain.

```
*KEYWORD
*INTERFACE_THICKNESS_CHANGE_COMPENSATION
$      IFLG      THK0
        1        1.2
*INCLUDE_COMPENSATION_CURRENT_TOOLS
rigid.inc
*INCLUDE_COMPENSATION_BEFORE_COMPESNATION
drawn.dynain
```

Revision Information:

This feature is available starting in Revision 106357.

***INTERFACE_WELDLINE_DEVELOPMENT**

Purpose: This keyword causes LS-DYNA to run a weld line development calculation instead of a finite element calculation. The input for this feature consists of (1) the formed blank from a completed metal forming simulation, (2) the corresponding initial blank, and (3) depending on which on desired whether the desired weld curve is on the formed or initial blank, the weld curve on the initial blank or on the final blank, respectively. Outputs include predicted final weld curve if input is the initial weld curve, or initial weld curve if input is the final welding curve; also nodes of any element edges that intersect the weld curve on the initial blank will be output to a file name affectednd_i.ibo and on the final blank to a file name affectednd_f.ibo.

Three additional keywords must be used together (and exclusively) with this keyword. They are: *INITIAL_BLANK, *FINAL_PART, and *WELDING_CURVE.

NOTE: When this card is present, LS-DYNA *does not* proceed to the finite element simulation.

Card set for *INTERFACE_WELDLINE_DEVELOPMENT.

Development Parameter Card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---------|---|---|---|---|---|---|---|
| Variable | IOPTION | | | | | | | |
| Type | I | | | | | | | |

|----------|-----------|---|---|---|---|---|---|---|
| Variable | FILENAME2 | | | | | | | |
| Type | A80 | | | | | | | |
| Default | none | | | | | | | |

Welding Curve Card. Following keyword *WELDING_CURVE:

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----------|---|---|---|---|---|---|---|
| Variable | FILENAME3 | | | | | | | |
| Type | A80 | | | | | | | |
| Default | none | | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|-----------|---|
| IOPTION | <p>Welding curve development options:</p> <p>EQ.1: Calculate initial weld curve from final (given) weld curve, with output file name weldline.ibo, which will be on the initial blank mesh.</p> <p>EQ.-1: Calculate final weld curve from initial weld curve, with output file name weldline_f.ibo, which will be on the formed blank mesh.</p> |
| FILENAME1 | Initial blank file name in keyword format. |
| FILENAME2 | Final formed blank file name in keyword format. |
| FILENAME3 | <p>File name of the weld curve defined using *DEFINE_CURVE_TRIM_3D, when IOPTION:</p> <p>EQ.1: Final (target) welding curve file name</p> <p>EQ.-1: Initial weld curve file name</p> |

General Remarks:

For metal forming of tailor welded blanks, an initial straight weld line could become a curve on the formed part. The amount of deviation of the formed weld curve from its initial line depends on the part shape and forming conditions. Sometimes the formed weld curve is not desirable; so a correction to the initial weld curve is needed. This card allows for determining the final weld curve given the initial weld curve and vice-versa, without performing another forming simulation.

Mesh with adaptivity for the initial blank and final part is supported.

Final (formed) Weld Curve:

The final formed weld curve should be projected onto the final blank mesh if it does not exactly lie on the mesh surface. This can be done with LS-PrePost4.2 via the menu option *GeoTol* → *Project* → *Project*, select *Closest Projection*, select *Project to Elements*, then define the destination mesh and source curves, and hit *Apply*. Sometimes the target curve may need enough points before projection; the points may be added via menu option *Curve* → *Spline* → *Method (Respace)* → *by number*. To write the curve out in ***DEFINE_CURVE_TRIM_3D** format, use *Curve* → *Convert* → *Method (To DEFINE_CURVE_TRIM)* → *To Key*, then write out the keyword using *FILE* → *Save Keyword*.

Computed Weld Curve (and IGES):

Computed weld curves are written with ***DEFINE_CURVE_TRIM_3D** keyword into a file called weldline.ibo (or, weldline_f.ibo, depending on the IOPTION). The format of this file follows the keyword's specification. LS-PrePost4.0 can convert the computed curve to IGES; see the procedure in the manual pages for ***INTERFACE_BLANKSIZE_DEVELOPMENT**. After hitting *Apply*, the curves will show up in the graphics window, and *File* → *Save as* → *Save Geom as* can be used to write the curves out in IGES format.

Example:

As shown in [Figure 26-41](#), given the initial (initialblank.k) and final blank (finalblank.k) configuration and a final formed weld curve (finalweldingcurve.k), the following input calculates a new initial weld curve on the initial blank. In this case, the final weld curve is specified as straight in the drawn panel.

```
*KEYWORD
*INTERFACE_WELDLINE_DEVELOPMENT
$OPTION
1
*INITIAL_BLANK
initialblank.k
*FINAL_PART
```

```
finalblank.k
*WELDING_CURVE
finalweldingcurve.k
*END
```

The output is the initial weld curve in the file weldline.ibo, [Figure 26-41](#). Nodes of element edges that intersect the initial weld curve are output in affectednd_i.ibo; while nodes of element edges that intersect the final formed weld curve are output in affectednd_f.ibo, [Figure 26-42](#).

To verify the predicted weld curve, the initial blank can be re-meshed according to the curve. A draw simulation can be performed again to confirm the final weld curve as straight, [Figure 26-43](#).

Likewise, if given an initial weld curve (initialweldingcurve.k) and a final weld curve (weldline_f.ibo) can be calculated with the keyword inputs below:

```
*KEYWORD
*INTERFACE_WELDLINE_DEVELOPMENT
$OPTION
-1
*INITIAL_BLANK
initialblank.k
*FINAL_PART
finalblank.k
*WELDING_CURVE
initialweldingcurve.k
*END
```

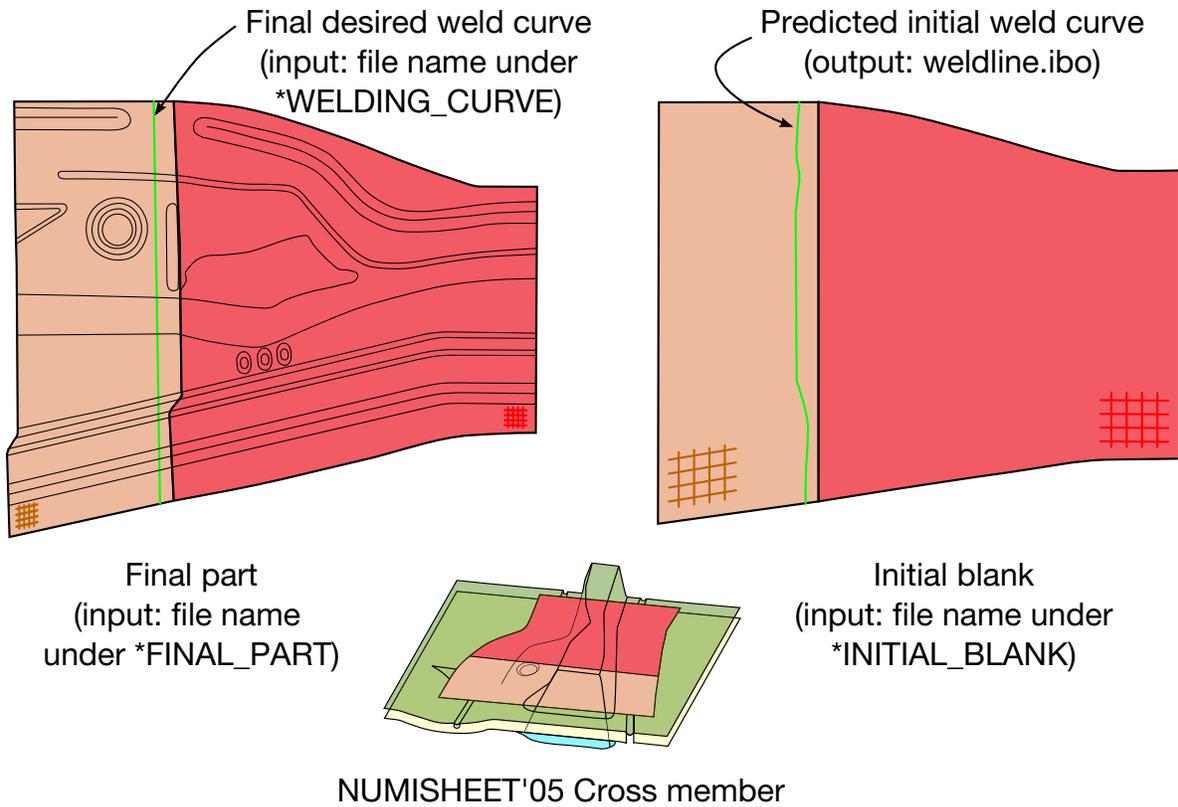

Figure 26-41. An example for a welding curve development.

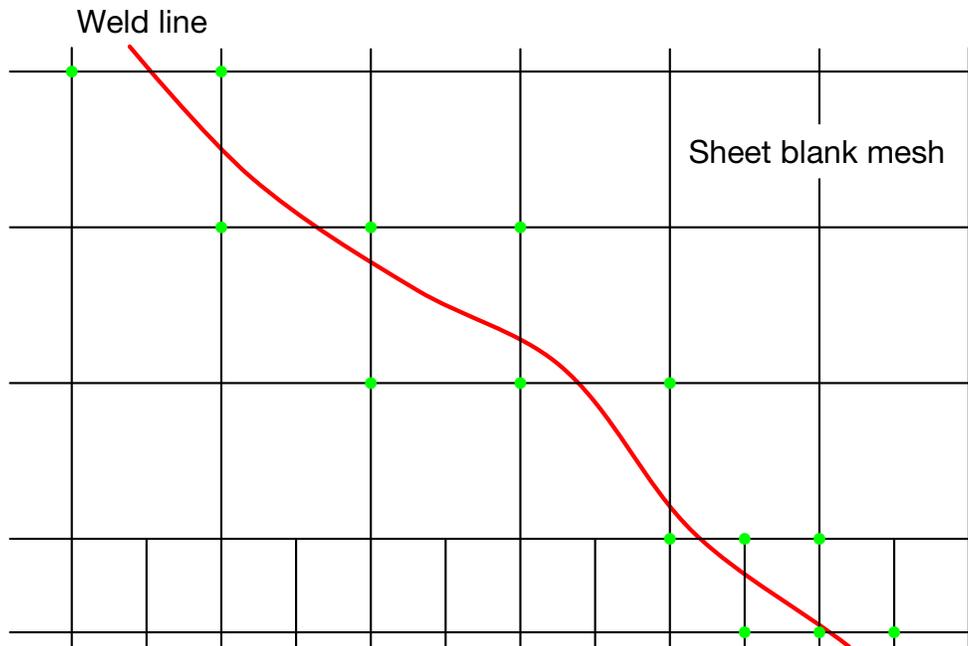

Figure 26-42. Nodes (in green) of element edges that intersect the weld curve are output in affectednd_i.ibo and affectednd_f.ibo, for initial and deformed mesh, respectively.

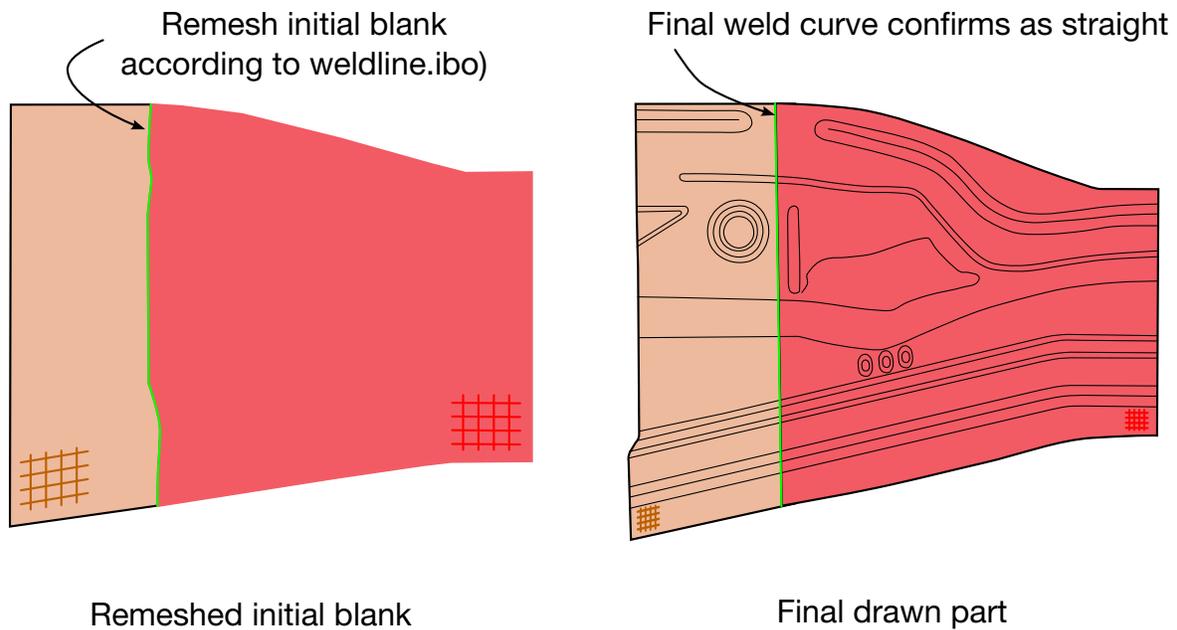

Figure 26-43. Verification run

Revision information:

1. IOPTION of "1": Revision 105189 in both double precision versions of SMP and MPP.
2. IOPTION of "-1": Revision 105727.
3. Output of nodes of element edges that intersect the weld curve: Revision 105727.
4. Later revisions may include improvements.

*KEYWORD

***KEYWORD**_{OPTION} {memory} {memory2 = j} {NCPU = n}

Available options include:

<BLANK>

ID

JOBID

Purpose: The keyword, ***KEYWORD**, flags LS-DYNA that the input deck is a keyword deck rather than the structured format, which has a strictly defined format. This must be the first card in the input file. Alternatively, by typing “keyword” on the execution line, keyword input formats are assumed and this beginning “***KEYWORD**” line is not required.

There are 3 optional parameters that can be specified on the ***KEYWORD** line. If a number {memory} is specified, it defines the memory size in units of words to be allocated. For MPP, if the parameter {memory2 = j} is also given, *memory* defines the memory allocation in words for the first core and *j* defines the memory allocation in words for each of the remaining cores. Note that if the memory size is specified on the execution line, it will override the memory size specified on the ***KEYWORD** line.

If the parameter {NCPU = n} is specified it defines the number Shared Memory Parallel (SMP) threads of “n” to be used for each processor during the analysis. This applies to both SMP and HYBRID versions of LS-DYNA.

For the Distributed Memory Version (MPP), the number of CPUs is defined with the “mpirun -np m” command.

HYBRID is combination of SMP and MPP therefore the total number of cores used in this example will be $n \times m$ cores. Defining the number of CPUs on the execution line overrides what is specified on the ***KEYWORD** line and both override the number of CPUs specified by ***CONTROL_PARALLEL**. An example of the {memory} and {NCPU = n} options would be as follows:

```
*KEYWORD 120m memory2=10m NCPU=2
```

This ***KEYWORD** command is requesting 12 million words of memory, 10 million words of memory2 and 2 CPUs to be used for the analysis with the consistency flag (see **CONST** in ***CONTROL_PARALLEL**) turned off. To run with the consistency flag turned on (recommended), set **NCPU** to a negative value, e.g., “**NCPU = -2**” runs with 2 CPUs with the consistency flag turned on.

*KEYWORD

The ID and JOBID command line options are available to add a prefix to all output and scratch file names, i.e., not the input filenames. This allows multiple simulations in a directory since a different prefix prevents files from being overwritten. If the ID option is used, the prefix is constructed of three user specified strings separated by “_f” characters.

ID Card. Additional Card if the ID option is active.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---------|---|------|---|-------|---|---|---|
| Variable | PROJECT | | NUM | | STAGE | | | |
| Type | A | | A | | A | | | |
| Default | none | | none | | none | | | |

VARIABLE

DESCRIPTION

| | |
|---------|---|
| PROJECT | First part of the output file name prefix. |
| NUM | Second part of the output file name prefix. |
| STAGE | Third part of the output file name prefix. |

By using the ID option of *KEYWORD, an output file name prefix may be specified as a combination of the variables PROJECT, NUM and STAGE as defined on Card 1 above. For example, if these variables were set literally to “PROJECT”, “NUM”, and “STAGE”, the first d3plot would be named:

PROJECT_NUM_STAGE.d3plot

Alternatively, an output file name prefix can be assigned by including “jobid=” on the execution line. For example,

lsdyna i=input.k jobid=PROJECT_NUM_STAGE

A third way to define an output file name prefix is by using the JOBID option of the *KEYWORD command, in which case Card 1 is defined as shown below and the variable JBID acts as the output prefix.

***KEYWORD**

JOBID Card. Additional card if the JOBID option is active.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | JBID | | | | | | | |
| Type | A | | | | | | | |
| Default | none | | | | | | | |

*LOAD

The keyword *LOAD provides a way of defining applied forces. The keyword control cards in this section are defined in alphabetical order:

*LOAD_ALE_CONVECTION_{*OPTION*}

*LOAD_BEAM_*OPTION*

*LOAD_BLAST

*LOAD_BLAST_ENHANCED

*LOAD_BLAST_SEGMENT

*LOAD_BLAST_SEGMENT_SET

*LOAD_BODY_*OPTION*

*LOAD_THERMAL_VARIABLE_NODE
*LOAD_THERMAL_VARIABLE_SHELL_{OPTION}
*LOAD_VOLUME_LOSS

***LOAD_ALE_CONVECTION_{OPTION}**

Purpose: Define the convection thermal energy transfer from a hot ALE fluid to the surrounding Lagrangian structure (Remark 1). It is associated with a corresponding coupling card defining the interaction between the ALE fluid and the Lagrangian structure. It is only used when thermal energy transfer from the ALE fluid to the surrounding Lagrangian structure is significant. This is designed specifically for airbag deployment applications where the heat transfer from the inflator gas to the inflator compartment can significantly affect the inflation potential of the inflator.

Available options include:

<BLANK>

ID

To define an ID number for each convection heat transfer computation in an optional card preceding all other cards for this command. This ID number can be used to output the part temperature and temperature change as functions of time in the *DATABASE_FSI card. To do this, set the CONVID parameter in the *DATABASE_FSI card equal to this ID.

ID Card. Additional card for ID keyword option.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|---|---|---|---|---|---|
| Variable | ID | TITLE | | | | | | |
| Type | I | A70 | | | | | | |
| Default | none | none | | | | | | |

Convection Card. Include as many cards as necessary. This input terminates at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|------|-------|------|--------|---|---|---|
| Variable | LAGPID | LAGT | LAGCP | H | LAGMAS | | | |
| Type | I | F | F | F | F | | | |
| Default | none | none | none | none | none | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| ID | ID number for each convection heat transfer computation |
| TITLE | A description of this convection heat transfer |
| LAGPID | Lagrangian PID (slave PID) from a corresponding coupling card which receives the thermal energy in the convection heat transfer |
| LAGT | Initial temperature of this Lagrangian slave part |
| LAGCP | Constant-pressure heat capacity of this Lagrangian slave part. It has a per-mass unit (for example, J/[kg*K]). |
| H | Convection heat transfer coefficient on this Lagrangian slave part surface. It is the amount of energy (J) transferred per unit area, per time, and per temperature difference. For example, its units may be J/[m ² *s*K]. |
| LAGMAS | The mass of the Lagrangian slave part receiving the thermal energy. This is in absolute mass unit (for example, kg). |

Remarks:

1. **Applications.** The only application of this card so far has been for the transfer of thermal energy from the ALE hot inflator gas to the surrounding Lagrangian structure (inflator canister and airbag-containing compartment) in an airbag deployment model.
2. **Model.** The heat transferred is taken out of the inflator gas thermal energy thus reducing its inflating potential. This is not a precise heat transfer modeling attempt. It is simply one mechanism for taking out excessive energy from the inflating potential of the hot inflator gas.

The heat transfer formulation may roughly be represented as the following equation. Some representative units are shown just for clarity.

$$[\dot{Q}] = [H \times A \times \Delta T] = \left(\frac{[E]}{[L]^2[t][T]} \right) \times [L]^2 \times [T] = [\text{Power}]$$

$$[\dot{Q}] = [\dot{M}C_p(T_{\text{Lag New}} - T_{\text{Lag Orig}})] = \left(\frac{[M]}{[t]} \right) \times \left(\frac{[E]}{[M][T]} \right) \times [T] = \frac{[E]}{[t]}$$

***LOAD_BEAM_OPTION**

Available options include:

ELEMENT

SET

Purpose: Apply the distributed traction load along any local axis of a beam or a set of beams. The local axes are defined in [Figure 28-1](#); see also *ELEMENT_BEAM.

Beam Cards. Include as many as necessary. This input stops at the next keyword (“*”) card.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|------|------|----|---|---|---|---|
| Variable | EID/ESID | DAL | LCID | SF | | | | |
| Type | I | I | I | F | | | | |
| Default | none | none | none | 1. | | | | |

VARIABLE

DESCRIPTION

EID/ESID

Beam ID (EID) or beam set ID (ESID), see *ELEMENT_BEAM or *SET_BEAM.

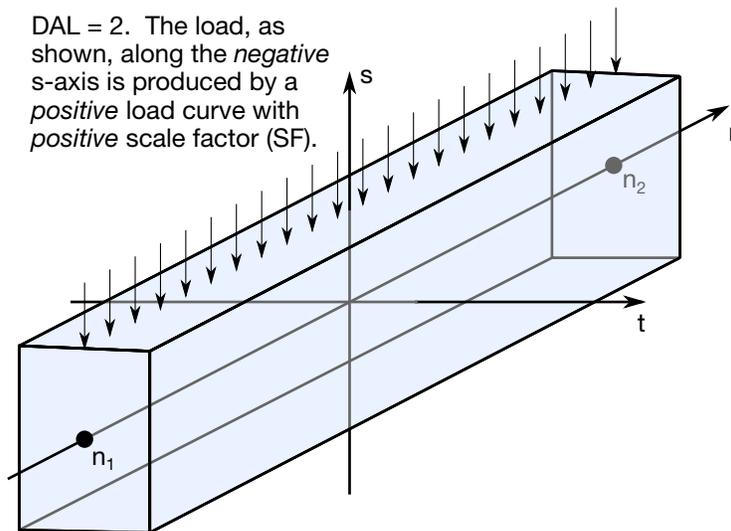

Figure 28-1. Applied traction loads are given in force per unit length. The *s* and *t*-directions are defined on the *ELEMENT_BEAM keyword.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| DAL | Direction of applied load: EQ.1: parallel to r -axis of beam, EQ.2: parallel to s -axis of beam, EQ.3: parallel to t -axis of beam. |
| LCID | Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION). See Remark 1 . |
| SF | Load curve scale factor. This is for a simple modification of the function values of the load curve. |

Remark:

1. **LCID Function Arguments.** The function defined by LCID has 7 arguments: time, the 3 current coordinates, and the 3 reference coordinates. For example, the function (see *DEFINE_FUNCTION),

$$f(t,x,y,z,x0,y0,z0) = -10.*\text{sqrt} ((x-x0)*(x-x0)+(y-y0)*(y-y0)+(z-z0)*(z-z0)),$$

applies a force proportional to the distance from the initial coordinates.

***LOAD_BLAST**

Purpose: Define an air blast function for the application of pressure loads from the detonation of conventional explosives. The implementation is based on a report by Randers-Pehrson and Bannister [1997] where it is mentioned that this model is adequate for use in engineering studies of vehicle responses due to the blast from land mines. This option determines the pressure values when used in conjunction with the keywords: *LOAD_SEGMENT, *LOAD_SEGMENT_SET, or *LOAD_SHELL.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|-----|-----|-----|-------|-------|---|
| Variable | WGT | XBO | YBO | ZBO | TBO | IUNIT | ISURF | |

| Default | none | 0.0 | 0.0 | 0.0 | 0.0 | 2 | 2 | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-------|---|---|---|
| Variable | CFM | CFL | CFT | CFP | DEATH | | | |
| Type | F | F | F | F | F | | | |
| Default | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | | | |

VARIABLE**DESCRIPTION**

| | |
|-----|---|
| WGT | Equivalent mass of TNT. |
| XBO | <i>x</i> -coordinate of point of explosion. |
| YBO | <i>y</i> -coordinate of point of explosion. |
| ZBO | <i>z</i> -coordinate of point of explosion. |
| TBO | Time-zero of explosion. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| IUNIT | Unit conversion flag. EQ.1: feet, pound-mass, seconds, psi EQ.2: meters, kilograms, seconds, pascals (default) EQ.3: inch, dozens of slugs, seconds, psi EQ.4: centimeters, grams, microseconds, megabars EQ.5: user conversions will be supplied (see Card 2) |
| ISURF | Type of burst. See Remark 2 . EQ.1: surface burst. The blast is located on or very near the ground, which is modeled as a surface. See Remark 5 . EQ.2: air burst. The blast is spherical (default). |
| CFM | Conversion factor: pounds per LS-DYNA mass unit. |
| CFL | Conversion factor: feet per LS-DYNA length units. |
| CFT | Conversion factor: milliseconds per LS-DYNA time unit. |
| CFP | Conversion factor: psi per LS-DYNA pressure unit |
| DEATH | Death time. Blast pressures are deactivated at this time. |

Remarks:

- Load Curves.** A minimum of two load curves, even if unreferenced, must be present in the model. Even though this keyword does not use load curves, unless there are at least two *DEFINE_CURVE cards LS-DYNA will error terminate with *LOAD_BLAST. Note that one of the enhancements of *LOAD_BLAST_ENHANCED is that it does not require two (place holding) load curves.
- Orientation.** The target's segments must be consistently oriented so that the normal vector of the portion of the target having a direct line of sight to the blast points roughly towards the blast. For example, segments defining a structure being blasted from the outside should have outwardly oriented normal vectors, whereas a cavity containing a blast should have inwardly facing normal vectors.
- Equivalent Mass of TNT.** Several methods can be used to approximate the equivalent mass of TNT for a given explosive. The simplest involves scaling

the mass by the ratio of the Chapman-Jouguet detonation velocities given the by:

$$M_{\text{TNT}} = M_e \frac{v_e^2}{v_{\text{TNT}}^2}$$

where M_{TNT} is the equivalent TNT mass and v_{TNT} is the Chapman-Jouguet (CJ) detonation velocity of TNT. M_e and v_e are, respectively, the mass and CJ velocity of the explosive under consideration. LS-DYNA takes the density of "Standard" TNT to be $1.57 \frac{\text{g}}{\text{cm}^3}$ and v_{TNT} to be $0.693 \frac{\text{cm}}{\mu\text{s}}$.

4. **Limits of Model's Validity.** Define a scaled distance, Z , as follows:

$$Z = \frac{R}{M_e^{1/3}}$$

where R is the distance from the charge center to the target and M_e is the equivalent TNT mass (see [Remark 3](#)). The scaled distance determines the range of validity for these models. The spherical airburst model is valid for Z ranging from $0.37 \text{ ft/lbm}^{1/3}$ ($0.147 \text{ m/kg}^{1/3}$) out to $100 \text{ ft/lb-m}^{1/3}$ ($40 \text{ m/kg}^{1/3}$). The hemispherical surface burst is valid for Z ranging from $0.45 \text{ ft/lbm}^{1/3}$ ($0.178 \text{ m/kg}^{1/3}$) out to $100 \text{ ft/lbm}^{1/3}$ ($40 \text{ m/kg}^{1/3}$).

5. **Surface Burst Model.** The surface blast model is ideal for when a charge is located on or very near the ground. In this case the initial blast wave is immediately reflected and reinforced by the nearly rigid ground (the model accounts for yielding) to produce a hemispherical reflected wave from the point of the burst. This reflected wave merges with the initial incident wave producing overpressures which are greater than those produced by the initial wave alone. Target points equidistant from the burst point are loaded identically with the surface burst option.
6. **Single Charge Limitation.** This feature cannot model multiple blasts in one simulation. Use `*LOAD_BLAST_ENHANCED` for multiple charges.

*LOAD

*LOAD_BLAST_ENHANCED

*LOAD_BLAST_ENHANCED

Purpose: Define an air blast function for the application of pressure loads due the detonation of a conventional explosive. While similar to *LOAD_BLAST, this feature includes enhancements for treating ground-reflected waves, moving warheads and multiple blast sources. The loads are applied to facets defined with the keyword *LOAD_BLAST_SEGMENT. A database containing blast pressure history is also available (see *DATABASE_BINARY_BLSFOR).

Card Summary:

Card Sets. Include as many sets of the following cards as necessary. This input terminates at the next keyword (“*”) card.

Card 1. This card is required.

| | | | | | | | |
|-----|---|-----|-----|-----|-----|------|-------|
| BID | M | XBO | YBO | ZBO | TBO | UNIT | BLAST |
|-----|---|-----|-----|-----|-----|------|-------|

Card 2. This card is required.

| | | | | | | | |
|-----|-----|-----|-----|-------|-------|--------|--|
| CFM | CFL | CFT | CFP | NIDBO | DEATH | NEGPHS | |
|-----|-----|-----|-----|-------|-------|--------|--|

Card 3a. This card is included if and only if BLAST = 3.

| | | | | | | | |
|-----|------|-------|-----|--|--|--|--|
| VEL | TEMP | RATIO | VID | | | | |
|-----|------|-------|-----|--|--|--|--|

Card 3b. This card is included if and only if BLAST = 4.

| | | | | | | | |
|------|------|--|--|--|--|--|--|
| GNID | GVID | | | | | | |
|------|------|--|--|--|--|--|--|

Data Cards:

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|-----|-----|-----|-----|------|-------|

| Default | none | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 2 | 2 |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| BID | Blast ID. A unique number must be defined for each blast source (charge). Multiple charges may be defined, however, interaction of the waves in air is not considered. |
| M | Equivalent mass of TNT (see Remark 1). |
| XBO | <i>x</i> -coordinate of charge center. |
| YBO | <i>y</i> -coordinate of charge center. |
| ZBO | <i>z</i> -coordinate of charge center. |
| TBO | Time of detonation. See Remark 3 . |
| UNIT | Unit conversion flag. See Remark 4 . EQ.1: pound-mass, foot, second, psi EQ.2: kilogram, meter, second, Pascal (default) EQ.3: dozen slugs (i.e., lbf-s ² /in), inch, second, psi EQ.4: centimeters, grams, microseconds, Megabars EQ.5: user conversions will be supplied (see Card 2) EQ.6: kilogram, millimeter, millisecond, GPa EQ.7: metric ton, millimeter, second, MPa EQ.8: gram, millimeter, millisecond, MPa |
| BLAST | Type of blast source (see Remark 5). EQ.1: hemispherical surface burst – charge is located on or very near the ground surface (see Remark 7) EQ.2: spherical air burst (default) – no amplification of the initial shock wave due to interaction with the ground surface EQ.3: air burst – moving non-spherical warhead EQ.4: air burst with ground reflection – initial shock wave impinges on the ground surface and is reinforced by the reflected wave to produce a Mach front. |

LOAD**LOAD_BLAST_ENHANCED**

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-------|------------------|--------|---|
| Variable | CFM | CFL | CFT | CFP | NIDBO | DEATH | NEGPHS | |
| Type | F | F | F | F | I | F | I | |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| CFM | Conversion factor - pounds per LS-DYNA mass unit. |
| CFL | Conversion factor - feet per LS-DYNA length units. |
| CFT | Conversion factor - milliseconds per LS-DYNA time unit. |
| CFP | Conversion factor - psi per LS-DYNA pressure unit. |
| NIDBO | Optional node ID representing the charge center. If non-zero then XBO, YBO, and ZBO are ignored. |
| DEATH | Death time. Blast pressures are deactivated at this time. |
| NEGPHS | Treatment of negative phase. EQ.0: negative phase dictated by the Friedlander equation. EQ.1: negative phase ignored as in ConWep. |

Moving Non-Spherical Warhead Card. Additional Card for BLAST = 3.

| Card 3a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|------|-------|------|---|---|---|---|
| Variable | VEL | TEMP | RATIO | VID | | | | |
| Type | F | F | F | F | | | | |
| Default | 0.0 | 70.0 | 1.0 | none | | | | |

VARIABLE**DESCRIPTION**

| | |
|-----|-------------------|
| VEL | Speed of warhead. |
|-----|-------------------|

| VARIABLE | DESCRIPTION |
|----------|---|
| TEMP | Ambient air temperature, Fahrenheit. |
| RATIO | Aspect ratio of the non- spheroidal blast front. This is the longitudinal axis radius divided by the lateral axis radius. Shaped charge and EFP warheads typically have significant lateral blast resembling an oblate spheroid with RATIO < 1. Cylindrically cased explosives produce more blast in the longitudinal direction, so RATIO > 1, rendering a prolate spheroid blast front, is more appropriate. |
| VID | Vector ID representing the longitudinal axis of the warhead (see *DEFINE_VECTOR). This vector is parallel to the velocity vector when a non-zero velocity VEL is defined. |

Spherical Air Burst with Ground Reflection Card. Additional card for BLAST = 4.

| Card 3b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|---|---|---|-------|---|---|
| Variable | GNID | GVID | | | | FLOOR | | |
| Type | I | I | | | | I | | |
| Default | none | none | | | | 0 | | |

| VARIABLE | DESCRIPTION |
|----------|--|
| GNID | ID of node residing on the ground surface. |
| GVID | ID of vector representing the vertically upward direction, that is, normal to the ground surface (see *DEFINE_VECTOR). |
| FLOOR | Treatment subterranean segments. EQ.0: Subterranean segments are not affected by the blast. EQ.1: Blast pressure is applied to segments residing below the ground plane. The pressure is computed for the ground plane location regardless of the segment's depth below the plane. |

Remarks:

1. **Equivalent Mass of TNT.** Several methods can be used to approximate the equivalent mass of TNT for a given explosive. The simplest involves scaling the mass by the ratio of the Chapman-Jouguet detonation velocities given by:

$$M_{\text{TNT}} = M_e \frac{v_e^2}{v_{\text{TNT}}^2}$$

where M_{TNT} is the equivalent TNT mass and v_{TNT} is the Chapman-Jouguet (CJ) detonation velocity of TNT. M_e and v_e are, respectively, the mass and CJ velocity of the explosive under consideration. LS-DYNA takes the density of "Standard" TNT to be 1.57 g/cm^3 and v_{TNT} to be $0.693 \text{ cm}/\mu\text{s}$.

2. **Orientation.** The target's segments must be consistently oriented so that the normal vector of the portion of the target having a direct line of sight to the blast points roughly towards the blast. Unless pressure is to be applied to the leeward side of a structure. For example, segments defining a structure being blasted from the outside should have outwardly oriented normal vectors, whereas a cavity containing a blast should have inwardly facing normal vectors. The angle of incidence is zero when the segment normal points directly at the charge. Only incident pressure is applied to a segment when the angle of incidence is greater than 90 degrees.
3. **Detonation Time.** The blast time offset TBO can be used to adjust the detonation time of the charge relative to the start time of the LS-DYNA simulation. The detonation time is delayed when TBO is positive. More commonly, TBO is set negative so that the detonation occurs before time-zero of the LS-DYNA calculation. Time is, therefore, not wasted while "waiting" for the blast wave to reach the structure. The following message, written to the message and d3hsp files as well as the screen, is useful for setting TBO:

```
Blast wave reaches structure at 2.7832E-01 milliseconds
```

For example, one might run LS-DYNA for one integration cycle and record the arrival time listed in the message above. Then TBO is set to a negative number slightly smaller in magnitude than the reported arrival time, for example $\text{TBO} = -0.275$ milliseconds. For this case, the blast wave would reach the structure shortly after the start of the simulation.

4. **Units.** Computation of blast pressure relies on an underlying method which uses base units of lbf-foot-millisecond-psi; note that this internal unit system is inconsistent. Calculations require that the system of units in which the LS-DYNA model is constructed must be converted to this internal set of units. Predefined and user-defined unit conversion factors are available (see the parameter UNIT) and these unit conversion factors are echoed back in the d3hsp

file. Below is an example of user-defined (UNIT = 5) conversion factors for the gm-mm-millisecond-MPa unit system.

$$1 = \left[\frac{\text{CFM} \times \text{lb}}{\text{LS-DYNA mass unit}} \right] = \left[\frac{2.2 \times 10^{-3}}{= \text{CFM}} \frac{\text{lbm}}{\text{gm}} \right]$$

$$1 = \left[\frac{\text{CFL} \times \text{ft}}{\text{LS-DYNA length unit}} \right] = \left[3.28 \times 10^{-3} \frac{\text{ft}}{\text{mm}} \right]$$

$$1 = \left[\frac{\text{CFT} \times \text{ms}}{\text{LS-DYNA time unit}} \right] = \left[1.0 \frac{\text{ms}}{\text{ms}} \right]$$

$$1 = \left[\frac{\text{CFP} \times \text{psi}}{\text{LS-DYNA pressure unit}} \right] = \left[145.0 \frac{\text{psi}}{\text{MPa}} \right]$$

5. **Limits of Model's Validity.** Define a scaled distance, Z , as follows:

$$Z = \frac{R}{M_e^{1/3}},$$

where R is the distance from the charge center to the target and M_e is the equivalent TNT mass (see [Remark 1](#)). The scaled distance determines the range of validity for these models. The spherical airburst model is valid for Z ranging from 0.37 ft/lbm^{1/3} (0.147 m/kg^{1/3}) out to 100 ft/lbm^{1/3} (40 m/kg^{1/3}). The hemispherical surface burst is valid for Z ranging from 0.45 ft/lbm^{1/3} (0.178 m/kg^{1/3}) out to 100 ft/lbm^{1/3} (40 m/kg^{1/3}).

For the spherical air burst with ground reflection (BLAST = 4), the same scaled distance can be used to determine validity, except R is now the height of the charge center above the ground. This model is valid for Z ranging from 1.0 ft/lbm^{1/3} (0.397 m/kg^{1/3}) out to 7.0 ft/lbm^{1/3} (2.78 m/kg^{1/3}).

6. **Axisymmetric Analyses.** Blast loads can be used in 2D axisymmetric analyses. Repeat the second node for the third and fourth nodes of the segment definition in *LOAD_BLAST_SEGMENT and *LOAD_BLAST_SEGMENT_SET.
7. **Surface Burst Model.** The surface blast model is ideal for when a charge is located on or very near the ground. In this case the initial blast wave is immediately reflected and reinforced by the nearly rigid ground (the model accounts for yielding) to produce a hemispherical reflected wave from the point of the burst. This reflected wave merges with the initial incident wave producing overpressures which are greater than those produced by the initial wave alone. Target points equidistant from the burst point are loaded identically with the surface burst option.

***LOAD_BLAST_SEGMENT**

Purpose: Apply blast pressure loading over a triangular or quadrilateral segment for 3D geometry or line segment for 2D geometry (see *LOAD_BLAST_ENHANCED).

Segment Cards. Include as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|--------|-------|--------|
| Variable | BID | N1 | N2 | N3 | N4 | ALEPID | SFNRB | SCALEP |
| Type | I | I | I | I | I | I | F | F |
| Default | none | none | none | none | none | none | 0. | 1. |

VARIABLE**DESCRIPTION**

| | |
|--------|---|
| BID | Blast source ID (see *LOAD_BLAST_ENHANCED). |
| N1 | Node ID. |
| N2 | Node ID. |
| N3 | Node ID. For line segments on two-dimensional geometries set N3 = N2. |
| N4 | Node ID. For line segments on two-dimensional geometries set N4 = N3 = N2 or for triangular segments in three diemensions set N4 = N3. |
| ALEPID | Part ID of ALE ambient part underlying this segment to be loaded by this blast (see *PART and *SECTION_SOLID, AET = 5). This applies only when the blast load is coupled to an ALE air domain. |
| SFNRB | Scale factor for the ambient element non-reflecting boundary condition. Shocks waves reflected back to the ambient elements can be attenuated with this feature. A value of 1.0 works well for most situations. The feature is disabled when a value of zero is specified |
| SCALEP | Pressure scale factor. |

***LOAD_BLAST_SEGMENT_SET**

Purpose: Apply blast pressure loading over each segment in a segment set (see *LOAD_BLAST_ENHANCED).

Segment Set Cards. Include as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|--------|-------|--------|---|---|---|
| Variable | BID | SSID | ALEPID | SFNRB | SCALEP | | | |
| Type | I | I | I | F | F | | | |
| Default | none | none | ↓ | 0. | 1. | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| BID | Blast source ID (see *LOAD_BLAST_ENHANCED). |
| SSID | Segment set ID (see *SET_SEGMENT). |
| ALEPID | Part ID of ALE ambient part underlying this segment to be loaded by this blast (see *PART and *SECTION_SOLID, AET = 5). This applies <i>only</i> when the blast load is coupled to an ALE air domain. |
| SFNRB | Scale factor for the ambient element non-reflecting boundary condition. Shocks waves reflected back to the ambient elements can be attenuated with this feature. A value of 1.0 works well for most situations. |
| SCALEP | Pressure scale factor. |

Remarks:

- Triangular Segments.** Triangular segments are defined by setting $N4 = N3$.
- Line Segments.** Line segments for two-dimensional geometries are defined by setting $N4 = N3 = N2$.

***LOAD_BODY_OPTION**

Available options include for base accelerations:

X

Y

Z

for angular velocities:

RX

RY

RZ

for loading in any direction, specified by vector components (see [About Keyword Option VECTOR](#)):

VECTOR

and to specify a part set:

PARTS

Purpose: Define body force loads due to a prescribed base acceleration or angular velocity using global axes directions. This option applies nodal forces only: it cannot be used to prescribe translational or rotational motion. These body forces do not take into account non-physical mass added via mass scaling; see *CONTROL_TIMESTEP.

NOTE: This data applies to all nodes in the complete problem unless a part subset is specified via the *LOAD_BODY_PARTS keyword.

If a part subset with *LOAD_BODY_PARTS, then all nodal points belonging to the subset will have body forces applied.

NOTE: Only one *LOAD_BODY_PARTS card is permitted per deck. To specify, for instance, one body load on one part and another body load on another part use *LOAD_BODY_GENERALIZED instead.

Card Summary:

Card 1a.1. This card is included if and only if the keyword option is X, Y, Z, RX, RY, RZ, or VECTOR.

| | | | | | | | |
|------|----|--------|----|----|----|-----|--|
| LCID | SF | LCIDDR | XC | YC | ZC | CID | |

VARIABLE

DESCRIPTION

N1/SID

Beginning node ID for body force load or the node or part set ID.

| VARIABLE | DESCRIPTION |
|----------|--|
| N2 | Ending node ID for body force load. Set to zero if a set ID is defined. |
| LCID | Load curve ID; see *DEFINE_CURVE. |
| DRLCID | Load curve ID for dynamic relaxation phase. Only necessary if dynamic relaxation is defined. See *CONTROL_DYNAMIC_RELAXATION. |
| XC | x -center of rotation. Define only for angular motion. |
| YC | y -center of rotation. Define only for angular motion. |
| ZC | z -center of rotation. Define only for angular motion. |
| AX | Scale factor for acceleration in x -direction |
| AY | Scale factor for acceleration in y -direction |
| AZ | Scale factor for acceleration in z -direction |
| OMX | Scale factor for x -angular velocity or acceleration |
| OMY | Scale factor for y -angular velocity or acceleration |
| OMZ | Scale factor for z -angular velocity or acceleration |
| CID | Coordinate system ID to define acceleration in the local coordinate system. The coordinate (XC, YC, ZC) is defined with respect to the local coordinate system if CID is nonzero. The accelerations, LCID and their scale factors are with respect to CID. EQ.0: global |
| ANGTYP | Type of body loads due to angular motion: EQ.CENT: body load from centrifugal acceleration, $\rho[\boldsymbol{\omega} \times (\boldsymbol{\omega} \times \mathbf{r})].$ EQ.CORI: body load from Coriolis-type acceleration, $2\rho(\boldsymbol{\omega} \times \mathbf{v}).$ EQ.ROTA: body load from rotational acceleration, $\rho(\boldsymbol{\alpha} \times \mathbf{r}),$ where $\boldsymbol{\omega}$ is the angular velocity, $\boldsymbol{\alpha}$ is the angular |

| VARIABLE | DESCRIPTION |
|----------|--|
| | acceleration, \mathbf{r} is the position vector relative to center of rotation and \mathbf{v} is the velocity vector |

Remarks:

1. **Base Accelerations.** Translational base accelerations allow body forces loads to be imposed on a structure. Conceptually, base acceleration may be thought of as accelerating the coordinate system in the direction specified, and, thus, the inertial loads acting on the model are of opposite sign. For example, if a cylinder were fixed to the yz -plane and extended in the positive x -direction, then a positive x -direction base acceleration would tend to shorten the cylinder, that is, create forces acting in the negative x -direction.
2. **Gravitational Loads.** Base accelerations are frequently used to impose gravitational loads during dynamic relaxation to initialize the stresses and displacements. During the analysis, in this latter case, the body forces loads are held constant to simulate gravitational loads. When imposing loads during dynamic relaxation, the load curve should slowly ramp up to avoid the excitation of a high frequency response.
3. **Angular Motion.** Body force loads due to the angular motion about an axis are calculated with respect to the deformed configuration. When $ANGYP = CENT$ or $CORI$, torsional effects which arise from changes in angular velocity are neglected. Such torsional effects can be taken into account by setting $ANGTYP = ROTA$. The angular velocity is assumed to have the units of radians per unit time, accordingly angular acceleration has the units of radians/time².
4. **Body Force Density.** The body force density is given at a point \mathbf{P} of the body by:

$$\mathbf{b} = \rho[\boldsymbol{\omega} \times (\boldsymbol{\omega} \times \mathbf{r})] ,$$

where ρ is the mass density, $\boldsymbol{\omega}$ is the angular velocity vector, and \mathbf{r} is a position vector from the origin to point \mathbf{P} . Although the angular velocity may vary with time, the effects of angular acceleration are included.

5. **Transient Deformation.** Angular velocities are useful for studying transient deformation of spinning three-dimensional objects. Typical applications have included stress initialization during dynamic relaxation where the initial rotational velocities are assigned at the completion of the initialization, and this option ceases to be active.

***LOAD_BODY_POROUS**

Purpose: Define the effects of porosity on the flow with body-force-like loads applied to the ALE element nodes. Ergun porous flow assumptions are used. This only applies to non-deformable (constant-porosity), fully saturated porous media. This model only works with a non-zero and constant viscosity fluid defined using either *MAT_NULL or *MAT_ALE_VISCOUS card.

Card Sets. Include as many sets of Cards 1 and 2 as necessary. This input terminates at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|-----|-----|-----|-----|-----|-----|
| Variable | SID | SIDTYP | AX | AY | AZ | BX | BY | BZ |
| Type | I | I | F | F | F | F | F | F |
| Default | none | 0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | AOPT | | | | | | | |
| Type | I | | | | | | | |
| Default | 0 | | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|------------|---|
| SID | Set ID of the ALE fluid part subjected to porous flow condition. |
| SIDTYP | Set ID type of the SID above: EQ.0: part set ID (default) EQ.1: part ID |
| AX, AY, AZ | Viscous coefficients for viscous terms in global x , y , and z directions (see Remark 1). If $A_x \neq 0.0$ and $A_y = A_z = 0.0$, then an isotropic viscous permeability condition is assumed for the porous medium. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| BX, BY, BZ | Inertial coefficients for inertia terms in global x , y , and z directions (see Remarks 1 and 2). If $B_x \neq 0.0$, and $B_y = B_z = 0.0$, then an isotropic inertial permeability condition is assumed for the porous medium. |
| AOPT | Material axis option: EQ.0: inactive. EQ.1: The forces are applied in a local system attached to the ALE solid (see CTYPE = 12 and DIREC = 1 in *CONSTRAINED_LAGRANGE_IN_SOLID). |

Remarks:

- Ergun Porous Flow Model.** Consider the basic general Ergun equation for porous flow in one direction:

$$\frac{\Delta P}{\Delta L} = \frac{\mu}{k_1} V_s + \frac{\rho}{k_2} V_s^2 ,$$

where

ρ = Fluid Density

μ = Fluid dynamic viscosity

$V_s = \frac{4Q}{\pi D^2}$ = Superficial fluid velocity

Q = Overall volume flow rate $\left(\frac{\text{m}^3}{\text{s}}\right)$

D = Porous channel characteristic width (perpendicular to ΔL)

$k_1 = \frac{\varepsilon^3 d_p^2}{150(1 - \varepsilon)^2}$ = Permeability parameter

$k_2 = \frac{\varepsilon^3 d_p}{1.75(1 - \varepsilon)}$ = Passability parameter

ε = Porosity = $\frac{\text{total pore volume}}{\text{total media volume}}$

d_p = Effective particle diameter

The above equation can be generalized into 3 dimensional flows where each component may be written as

$$-\frac{dP}{dx_i} = A_i \mu V_i + B_i \rho |V_i| V_i$$

where $i = 1,2,3$ refers to the global coordinate directions (no summation intended for repeated indices), μ is the constant dynamic viscosity, ρ is the fluid densi-

ty, V_i is the fluid velocity components, A_i is analogous to k_1 above, and B_i is analogous to k_2 above. A matrix version can be defined by ALE elements with *DEFINE_POROUS_ALE.

2. **Inertia Coefficients.** If $B_i = 0$, the equation is reduced to simple Darcy Law for porous flow (may be good for sand-like flow). For coarse grain (rocks) media, the inertia term will be important and the user needs to input these coefficients.

*LOAD

*LOAD_BRODE

*LOAD_BRODE

Purpose: Define Brode function for application of pressure loads due to explosion; see Brode [1970]. See also *LOAD_SEGMENT, *LOAD_SEGMENT_SET, or *LOAD_SHELL.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-----|-----|------|------|
| Variable | YLD | BHT | XBO | YBO | ZBO | TBO | TALC | SFLC |
| Type | F | F | F | F | F | F | I | I |
| Default | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0 | 0 |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|---|---|---|---|---|
| Variable | CFL | CFT | CFP | | | | | |
| Type | F | F | F | | | | | |
| Default | 0.0 | 0.0 | 0.0 | | | | | |

VARIABLE

DESCRIPTION

| | |
|-----|---|
| YLD | Yield, W , (Kt, equivalent tons of TNT). This parameter is constant yield unless SFLC is defined. In that case it becomes a parameter for calculating the variable yield where it will be referenced as YLD. See Remark 1 . |
| BHT | Height of burst. |
| XBO | x -coordinates of Brode origin. |
| YBO | y -coordinates of Brode origin. |
| ZBO | z -coordinates of Brode origin. |
| TBO | Time offset of Brode origin. |

| VARIABLE | DESCRIPTION |
|----------|--|
| TALC | Load curve number giving time of arrival as a function of range relative to Brode origin (space, time). See *DEFINE_CURVE and Remark 1 . |
| SFLC | Load curve number giving yield scaling, W_s , as a function of scaled time. Scaled time is time relative to the Brode origin, t_B , divided by $YLD^{1/3}$, that is, $t_B/YLD^{1/3}$. See *DEFINE_CURVE and Remark 1 . |
| CFL | Conversion factor - kft to LS-DYNA length units. |
| CFT | Conversion factor - milliseconds to LS-DYNA time units. |
| CFP | Conversion factor - psi to LS-DYNA pressure units. |

Remarks:

1. **Yield Parameter.** If the curves, TALC and SFLC, are defined, a variable yield as opposed to a constant yield is assumed. *Both* load curves must be specified for the variable yield option. If this option is used, the shock time of arrival is found from the time of arrival curve. The yield used in the Brode formulas is computed by taking the yield scaling value, W_s , at the current scaled time ($t_B/YLD^{1/3}$) and multiplying W_s by the constant yield input in field YLD, that is,

$$W \Big|_{t_B} = W_s \Big|_{t_B/YLD^{1/3}} \times YLD .$$

***LOAD_DENSITY_DEPTH**

Purpose: Define density versus depth for gravity loading. This option has been occasionally used for analyzing underground and submerged structures where the gravitational preload is important. The purpose of this option is to initialize the hydrostatic pressure field at the integration points in the element. See also GRAV in *PART.

This card should be only defined once in the input deck.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|-----|------|---|---|---|---|
| Variable | PSID | GC | DIR | LCID | | | | |
| Type | I | F | I | I | | | | |
| Default | 0 | 0.0 | 1 | none | | | | |
| Remarks | 1,2 | | | 3 | | | | |

VARIABLE**DESCRIPTION**

| | |
|------|---|
| PSID | Part set ID, see *SET_PART. If a PSID of zero is defined, then all parts are initialized. |
| GC | Gravitational acceleration value. |
| DIR | Direction of loading: EQ.1: global x , EQ.2: global y , EQ.3: global z . |
| LCID | Load curve ID defining density as a function of depth; see *DEFINE_CURVE. |

Remarks:

- Hydrostatic Pressure.** Density as a function of depth curves are used to initialize hydrostatic pressure due to gravity acting on an overburden material. The hydrostatic pressure acting at a material point at depth, d , is given by:

$$p = - \int_d^{d_{\text{surface}}} \rho(z)g dz ,$$

where p is pressure, d_{surface} is the depth of the surface of the material to be initialized (usually zero), $\rho(z)$ is the mass density at depth z , and g is the acceleration of gravity. This integral is evaluated for each integration point. Depth may be measured along any of the global coordinate axes, and the sign convention of the global coordinate system should be respected. The sign convention of gravity also follows that of the global coordinate system. For example, if the positive z -axis points "up", then gravitational acceleration should be input as a negative number.

2. **Limitations.** For this option there is a limit of 12 parts that can be defined by PSID, unless all parts are initialized.
3. **Depth LCID.** Depth is the ordinate of the curve and is input as a descending x , y , or z coordinate value. Density is the abscissa of the curve and must vary (increase) with depth, that is, an infinite slope is not allowed.

*LOAD

*LOAD_ERODING_PART_SET

*LOAD_ERODING_PART_SET

Purpose: Apply a pressure load to the exposed surface composed of solid elements that may erode.

Card Sets. Include as many sets of Cards 1 and 2 as necessary. This input terminates at the next keyword ("*") card.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-----|-----|------|-------|-----|-------|
| Variable | ID | LCID | SF | AT | PSID | BOXID | MEM | ALPHA |
| Type | I | I | F | F | I | I | I | F |
| Default | none | none | 1.0 | 0.0 | none | 0 | 50 | 80 |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-----|-----|-----|------|---|---|---|
| Variable | IFLAG | X | Y | Z | BETA | | | |
| Type | I | F | F | F | F | | | |
| Default | 0 | 0.0 | 0.0 | 0.0 | 90 | | | |

VARIABLE

DESCRIPTION

| | |
|-------|---|
| ID | ID number. |
| LCID | Load curve ID defining pressure as a function of time; see *DEFINE_CURVE. |
| SF | Scale factor. |
| AT | Arrival time. |
| PSID | Part set ID; see *SET_PART. |
| BOXID | Box ID; see *DEFINE_BOX. Any segment that would otherwise be loaded but whose centroid falls outside of this box is not loaded. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| MEM | Extra memory, in percent, to be allocated above the initial memory for storing the new load segments exposed by the erosion. |
| ALPHA | The maximum angle (in degrees) permitted between the normal of a segment at its centroid and the average normal at its nodes. This angle is used to eliminate interior segments. |
| IFLAG | Flag for choosing a subset of the exposed surface that is oriented towards a blast or other loading source. The vector from the center of the element to the source location must be within an angle of BETA of the surface normal. If IFLAG > 0, then the subset is chosen, otherwise if IFLAG = 0, the entire surface is loaded. |
| X, Y, Z | Optional source location. |
| BETA | Maximum permitted angle (in degrees) between the surface normal and the vector to the source. The exposed segment is not loaded if the calculated angle is greater than BETA. |

Remarks:

- 1. LCID.** If LCID is input as:
 - a) -1, then the Brode function is used to determine the pressure for the segments; see *LOAD_BRODE.
 - b) -2, then an empirical air blast function is used to determine the pressure for the segments; see *LOAD_BLAST.
- 2. Load Curve Multipliers.** The load curve multipliers may be used to increase or decrease the pressure. The time value is not scaled.
- 3. Activation Time.** The activation time, AT, is the time during the solution that the pressure begins to act. Until this time, the pressure is ignored. The function value of the load curves will be evaluated at the offset time given by the difference of the solution time and AT, that is solution time – AT.
- 4. Requirements.** For proper evolution of the loaded surface, it is a requirement that DTMIN in *CONTROL_TERMINATION be greater than zero and ERODE in *CONTROL_TIMESTEP be set to 1.

***LOAD_GRAVITY_PART_{OPTION}**

Available options are:

<BLANK>

SET

Purpose: Define gravity for individual parts. This feature is intended for use with *LOAD_STIFFEN_PART to simulate staged construction. This keyword is available for solids, shells and thick shells as well as beam element types 1, 2, 3, 4, 5, 6, 9, 11, 12 and 13.

Part Cards. Include this card as many times as necessary. This input ends at the next keyword ("**") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-----|-------|------|------|------|---|
| Variable | PID | DOF | LC | ACCEL | LCDR | STGA | STGR | |
| Type | I | I | I | F | I | I | I | |
| Default | none | none | 1.0 | 0 | none | 0 | 0 | |

VARIABLE**DESCRIPTION**

| | |
|----------|--|
| PID/PSID | Part ID (or Part Set ID for the SET option) for application of gravity load |
| DOF | Direction: enter 1, 2 or 3 for x , y or z |
| LC | Load curve defining factor as a function of time (or zero if STGA, STGR are defined). See Remark 1 . |
| ACCEL | Acceleration (will be multiplied by factor from curve) |
| LCDR | Load curve defining as a function of time during dynamic relaxation |
| STGA | Construction stage at which part is added (optional) |
| STGR | Construction stage at which part is removed (optional) |

Remarks:

1. **Defining Gravity Load.** There are 3 options for defining how the gravity load on a part varies with time.
 - a) Curve LC gives factor as a function of time. This overrides the other methods if LC is non-zero. A constant factor of 1.0 is assumed if LC is not specified.
 - b) STGA, STGR refer to stages at which part is added and removed – the stages are defined in *DEFINE_CONSTRUCTION_STAGES. If STGA is zero, the gravity load starts at time zero. If not, it ramps up from the small factor FACT (on *CONTROL_STAGED_CONSTRUCTION) up to full value over the ramp time ATR at the start of stage STGA (see *DEFINE_CONSTRUCTION_STAGES). If STGR is zero, the gravity load continues until the end of the analysis. If not, it ramps down from full value to FACT over the ramp time ATR at the start of stage STGR.
 - c) *DEFINE_STAGED_CONSTRUCTION_PART can be used instead of *LOAD_GRAVITY_PART to define this loading. During initialization, a *LOAD_GRAVITY_PART card will be created and the effect is the same as using the STGA, STGR method described above; ACCEL is then taken from *CONTROL_STAGED_CONSTRUCTION.
2. **Mass Loading.** This feature calculates the loading from the mass of the elements of the referenced parts only (density × volume). This mass does not include any attached lumped mass elements. Only solid, beam, shell and thick shell elements can be loaded.

***LOAD_HEAT_CONTROLLER**

Purpose: Used to define a thermostat control function. The thermostat controls the heat generation within a material by monitoring a remote nodal temperature. Control can be specified as on-off, proportional, integral, or proportional with integral.

Sensor Node Cards. Include up to 20 cards. This input ends at the next keyword ("**") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|---|
| Variable | NODE | PID | LOAD | TSET | TYPE | GP | GI | |
| Type | I | I | F | F | I | F | F | |
| Default | none | |

VARIABLE**DESCRIPTION**

| | |
|------|--|
| NODE | Sensor is located at this node number. |
| PID | Part ID assigned to the elements modeling the heater or cooler being controlled. |
| LOAD | Heater output q_0 . [typical units: W/m ³] |
| TSET | Controller set point temperature at the location identified by NODE. |
| TYPE | Type of control function. EQ.1: on-off EQ.2: proportional + integral |
| GP | Proportional gain. |
| GI | Integral gain. |

Remarks:

The thermostat control function is

$$\dot{q}''' = \dot{q}_0''' \left[G_P (T_{\text{set}} - T_{\text{node}}) + G_I \int_{t=0}^t (T_{\text{set}} - T_{\text{node}}) dt \right]$$

***LOAD_HEAT_GENERATION_OPTION**

Available options include:

- SOLID
- SET_SOLID
- SHELL
- SET_SHELL

Purpose: Define elements or element sets with heat generation.

Generation Cards. Include as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|--------|--------|--------|---|---|
| Variable | SID | LCID | MULT | WBLCID | CBLCID | TBLCID | | |
| Type | I | I | F | I | I | I | | |
| Default | none | none | 0. | 0 | 0 | 0 | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| SID | Element ID or element set ID, see *ELEMENT_SOLID, *SET_SOLID, *ELEMENT_SHELL, and *SET_SHELL, respectively. |
| LCID | Volumetric heat generation rate, \dot{q}''' , specification. SI units are W/m ³ . This parameter can reference a load curve ID (see *DEFINE_CURVE) or a function ID (see *DEFINE_FUNCTION and Remark 1). When the reference is to a curve, LCID has the following interpretation: GT.0: \dot{q}''' is defined by a curve consisting of (time, \dot{q}''') data pairs. EQ.0: \dot{q}''' is a constant defined by the value MULT. LT.0: \dot{q}''' is defined by a curve consisting of (temperature, \dot{q}''') data pairs. Enter -LCID on the DEFINE_CURVE keyword. |
| MULT | Volumetric heat generation, \dot{q}''' , curve multiplier. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| WBLCID | Load curve ID defining the blood perfusion rate [e.g., kg/m ³ sec] as a function of time. |
| CBLCID | Load curve ID defining the blood specific heat [e.g., J/kg C] as a function of the blood temperature. |
| TBLCID | Load curve ID defining the blood temperature [e.g., C] as a function of time. |

Remarks:

1. If LCID references a DEFINE_FUNCTION, the following function arguments are allowed $f(x, y, z, v_x, v_y, v_z, T, t)$ where:
 - x, y, z = element centroid coordinates
 - v_x, v_y, v_z = element centroid velocity components
 - T = element integration point temperature
 - t = solution time
2. Rate of heat transfer from blood to tissue = $W_b C_b (T_b - T)$ [units: J/m³ sec]

***LOAD_MASK**

Purpose: Apply a distributed pressure load over a three-dimensional shell part. The pressure is applied to a subset of elements that are within a fixed global box and lie either outside or inside of a closed curve in space which is projected onto the surface.

Card Sets. Include as many sets of Cards 1 and 2 as necessary. This input terminates at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|-----|-------|-------|------|-------|
| Variable | PID | LCID | VID1 | OFF | BOXID | LCIDM | VID2 | INOUT |
| Type | I | I | I | F | I | I | I | I |
| Default | none | none | 0 | 0. | ↓ | 0 | none | 0 |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|---|---|---|---|---|---|---|
| Variable | ICYCLE | | | | | | | |
| Type | I | | | | | | | |
| Default | 200 | | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|------|--|
| PID | Part ID (PID). This part must consist of three-dimensional shell elements. To use this option with solid elements the surface of the solid elements must be covered with null shells. See *MAT_NULL. |
| LCID | Curve ID defining the pressure time history, see *DEFINE_CURVE. |
| VID1 | Vector ID normal to the surface on which the applied pressure acts. Positive pressure acts in a direction that is in the opposite direction. This vector may be used if the surface on which the pressure acts is relatively flat. |

EQ.0: the pressure load depends on the orientation of the shell

| VARIABLE | DESCRIPTION |
|----------|--|
| | elements as shown in Figure 28-5 . |
| OFF | Pressure loads will be discontinued if $ \text{VID1} \cdot \mathbf{n}_{\text{shell}} < \text{OFF}$, where $\mathbf{n}_{\text{shell}}$ is the normal vector to the shell element. |
| BOXID | Only elements inside the box with part ID, PID, are considered. If no ID is given, all elements of PID, are included. When the active list of elements is updated, elements outside the box will no longer have pressure applied, that is, the current configuration is always used. |
| LCIDM | Curve ID defining the mask. This curve defines (x,y) pairs of points in a local coordinate system defined by the vector ID, VID2. Generally, the curve should form a closed loop, that is, the first point is identical to the last point, and the curve should be flagged as a DATTYP = 1 curve in the *DEFINE_CURVE section. If no curve ID is given, all elements of PID are included with the exception of those deleted by the box. The mask works like the trimming option; see DEFINE_CURVE_TRIM and Figure 15-23 . |
| VID2 | Vector ID used to project the masking curve onto the surface of part ID, PID. The origin of this vector determines the origin of the local system that the coordinates of the PID are transformed into prior to determining the pressure distribution in the local system. This vector must be defined if LCIDM is nonzero. See Figure 15-23 . |
| INOUT | Flag for applying pressure to elements inside or outside of projected curve: <p data-bbox="508 1377 1406 1453">EQ.0: elements whose center falls inside the projected curve are considered.</p> <p data-bbox="508 1472 1406 1541">EQ.1: elements whose center falls outside the projected curve are considered.</p> |
| ICYCLE | Number of time steps between updating the list of active elements. The list update can be quite expensive and should be done at a reasonable interval. The default is not appropriate for all problems. |

***LOAD_MOTION_NODE**

Purpose: Apply a concentrated nodal force or moment to a node based on the motion of another node.

Node Cards. Include as many cards as desired. This input ends at the next keyword ("*") card.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|------|------|----|--------|-------|------|--------|
| Variable | NODE1 | DOF1 | LCID | SF | CID1 | NODE2 | DOF2 | CID2 |
| Type | I | I | I | F | I | I | I | I |
| Default | none | none | none | 1. | global | none | none | global |

VARIABLE**DESCRIPTION**

| | |
|-------|---|
| NODE1 | Node ID for the concentrated force. |
| DOF1 | Applicable degrees-of-freedom: EQ.1: x -direction of load action, EQ.2: y -direction of load action, EQ.3: z -direction of load action, EQ.4: moment about the x -axis, EQ.5: moment about the y -axis, EQ.6: moment about the z -axis. |
| LCID | Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION). The applied force is a function of the applicable degree-of-freedom of NODE2. |
| SF | Load curve scale factor. |
| CID1 | Coordinate system ID (optional). See Remark 1 . |
| NODE2 | Node ID for calculating the force. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| DOF2 | Applicable degrees-of-freedom: EQ.1: x -coordinate EQ.2: y -coordinate, EQ.3: z -coordinate, EQ.4: x -translational displacement, EQ.5: y -translational displacement, EQ.6: z -translational displacement, EQ.7: rotational displacement about the x -axis, EQ.8: rotational displacement about the y -axis, EQ.9: rotational displacement about the z -axis. EQ.10: x -translational velocity, EQ.11: y -translational velocity, EQ.12: z -translational velocity, EQ.13: rotational velocity about the x -axis, EQ.14: rotational velocity about the y -axis, EQ.15: rotational velocity about the z -axis. |
| CID2 | Coordinate system ID (optional); see Remark 1 . |

Remarks:

1. **Coordinate System.** The global coordinate system is the default. The local coordinate system IDs are defined in the *DEFINE_COORDINATE_SYSTEM section.

***LOAD_MOVING_PRESSURE**

Purpose: Apply moving pressure loads to a nondisjoint surface. The pressure loads approximate a jet of high velocity fluid impinging on the surface. Multiple surfaces may be defined each acted on by a set of nozzles.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|---|---|---|---|---|---|---|
| Variable | LOADID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

Nozzle Cards. Define the following cards for each nozzle. Include as many cards as desired. This input ends at the first card with the second field (NODE2) ≤ 3 .

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|------|--------|-------|-------|---|---|
| Variable | NODE1 | NODE2 | LCID | CUTOFF | LCIDT | LCIDD | | |
| Type | I | I | I | F | I | I | | |
| Default | none | none | none | none | 0 | 0 | | |

The following card defines the surface where the nozzles act.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|-----|---|---|---|---|---|
| Variable | ID | IDTYPE | NIP | | | | | |
| Type | I | I | I | | | | | |
| Default | none | none | 3x3 | | | | | |

VARIABLE**DESCRIPTION**

LOADID

Loading ID.

NODE1

Node located at the origin of the nozzle.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| NODE2 | Node located at the head of the nozzle |
| LCID | Load curve or function (see *DEFINE_FUNCTION) ID defining pressure versus radial distance from the center of the jet. |
| CUTOFF | Outer radius of jet. The pressure acting outside this radius is set to zero. |
| LCIDT | Load curve or function (see *DEFINE_FUNCTION) ID, which scales the pressure as a function of time. If a load curve isn't specified, the scale factor defaults to 1.0. |
| LCIDD | Load curve or function (see *DEFINE_FUNCTION) ID, which scales the pressure as a function of distance from the nozzle. If a load curve isn't specified, the scale factor defaults to 1.0. |
| ID | Segment set ID, shell element set ID, part set ID, or part ID. See IDT below. |
| IDT | Slave segment or node set type. The type must correlate with the number specified for SSID: EQ.0: segment set ID for surface-to-surface contact, EQ.1: shell element set ID for surface-to-surface contact, EQ.2: part set ID, EQ.3: part ID, |
| NIP | Number of integration in segment used to compute pressure loads. |

***LOAD_NODE_OPTION**

Available options include:

POINT

SET

Purpose: Apply a concentrated nodal force to a node or each node in a set of nodes.

Node/Node Set Cards. Include as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|------|------|----|--------|----|----|----|
| Variable | NID/NSID | DOF | LCID | SF | CID | M1 | M2 | M3 |
| Type | I | I | I | F | I | I | I | I |
| Default | none | none | none | 1. | global | ↓ | ↓ | ↓ |

VARIABLE**DESCRIPTION**

NID/NSID

Node ID or nodal set ID (NSID); see **SET_NODE_OPTION*.

DOF

Applicable degrees-of-freedom:

EQ.1: x -direction of load action,

EQ.2: y -direction of load action,

EQ.3: z -direction of load action,

EQ.4: follower force (see [Remark 2](#)),

EQ.5: moment about the x -axis (see [Remark 4](#)),

EQ.6: moment about the y -axis axis (see [Remark 4](#)),

EQ.7: moment about the z -axis axis (see [Remark 4](#)),

EQ.8: follower moment (see [Remarks 2 and 4](#)).

LCID

Load curve ID (see **DEFINE_CURVE*) or function ID (see **DEFINE_FUNCTION* and [Remark 5](#) below).

SF

Load curve scale factor.

CID

Coordinate system ID (optional); see [Remark 1](#).

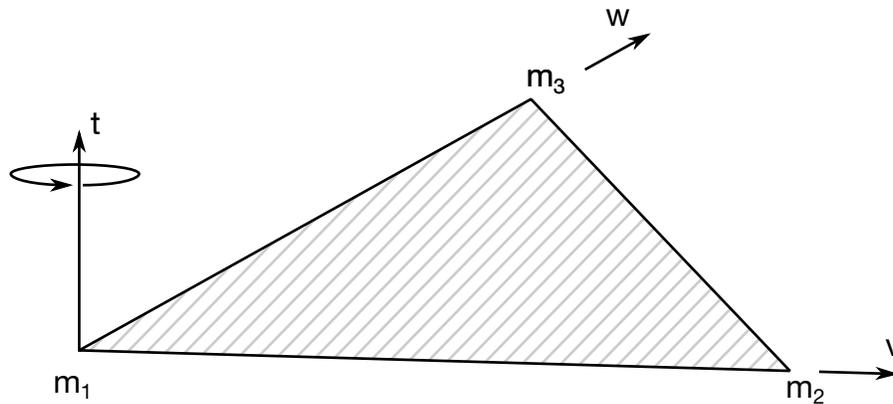

Figure 28-3. Nodes M1, M2, and M3 define a plane. A positive follower force acts in the positive t -direction of that plane, that is, along the normal vector of the plane. A positive follower moment puts a counterclockwise torque about the normal vector. The normal vector is found by the cross product $\mathbf{t} = \mathbf{v} \times \mathbf{w}$ where \mathbf{v} and \mathbf{w} are vectors as shown.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| M1 | Node 1 ID. Only necessary if DOF = 4 or 8; see Remark 2 below. |
| M2 | Node 2 ID. Only necessary if DOF = 4 or 8; see Remark 2 below. |
| M3 | Node 3 ID. Only necessary if DOF = 4 or 8; see Remark 2 below. |

Remarks:

1. **Coordinate Systems.** The global coordinate system is the default. If CID is nonzero, the local coordinate is defined using `*DEFINE_COORDINATE_option`, and furthermore, if `*DEFINE_COORDINATE_NODES` is used with `FLAG=1` to define the local coordinate system, the local coordinate system and thus the direction of the applied load is updated with time; otherwise the direction of the load is static. An alternative way to update the direction of the load is to use the follower forces option (see next remark).
2. **Follower Forces.** The current position of nodes M1, M2, and M3 are used to control the direction of a follower force. A positive follower force acts normal to the plane defined by these nodes, and a positive follower moment puts a counterclockwise torque about the t -axis. These actions are depicted in [Figure 28-3](#). An alternative way to define the force direction is by setting M3 to any non-positive value, in which case the follower force is in the M1 to M2 direction.
3. **Axisymmetric Elements with Area and Volume Weighting.** For shell formulations 14 and 15, the axisymmetric solid elements with area and volume

***LOAD_NURBS_SHELL_{OPTION}**

The following option is available to define an ID for the load applied to a NURBS shell patch:

ID

If the ID is defined, an additional card is required.

Purpose: Apply a load over a NURBS shell patch.

Card Summary:

ID. This card is included if and only if the ID option is used.

| | |

|-----------------|---|
| SSID | NURBS shell patch ID; see *ELEMENT_SHELL_NURBS_PATCH. |
| LCID | Load curve ID |
| SF | Load curve scale factor |
| AT | Arrival/birth time for load. |
| DT | Death time for load. |

| VARIABLE | DESCRIPTION |
|----------|--|
| LTYPE | <p>Load type. Default = "PRESS".</p> <p>EQ.CRV: Loading is applied on a curve on a NURBS patch, along (V1,V2,V3) of CID coordinate system. The loading dimension is force per unit length along the curve.</p> <p>EQ.CRVS: Loading, force per unit length, is applied on a curve on the surface of a NURBS patch, along the local shear direction, CS direction, in Figure 28-4.</p> <p>EQ.CRVT: Loading, force per unit length, is applied on a curve on the surface of a NURBS patch, along the local transverse direction, CT direction, in Figure 28-4.</p> <p>EQ.CRVN: Loading, force per unit length, is applied on a curve on the surface of a NURBS patch, along the local normal direction, CN direction, in Figure 28-4.</p> <p>EQ.PRESS: Surface traction is applied on a region on a NURBS patch, along the opposite direction to the NURBS patch surface normal. The loading unit is force per unit area of the region.</p> <p>EQ.TRACT: Surface traction, force per unit area, is applied on a region on a NURBS patch, along (V1,V2,V3) of the coordinate system CID.</p> |
| REGDEF | <p>The method of defining the region of a NURBS shell patch on which the loading is applied. Default = "RS".</p> <p>When LTYPE = "PRESS" or "TRACT":</p> <p>EQ.RS: The extreme values of the univariate knot vector in local r and s-directions are used to define the traction application region; see RK_i and SK_i of *ELEMENT_SHELL_NURBS_PATCH. When not defined, the whole NURBS shell patch is subject to the traction.</p> <p>EQ.NBEW: The traction loading is applied to the whole NURBS-element which is identified by an interior node on the surface of the NURBS-element, such as NE1 through NE4 in Figure 28-4.</p> <p>EQ.NBEP: The traction loading is applied to part of a NURBS-element which is identified by four nodes on the surface of the NURBS-element, such as NT1 through NT4 in Figure 28-4.</p> |

| VARIABLE | DESCRIPTION |
|----------|---|
| | When LTYPE = "CRV," "CRVS," "CRVT," or "CRVN": |
| EQ.RS: | The values of (RK, SK) of the starting point and the ending point of a curve. NC1 and NC2 in Figure 28-4 , on the surface of the NURBs shell patch are used to define the curve loading application region. |
| EQ.NBEP: | The curve loading is applied to a curve on a NURBS-element which is identified by two nodes on the surface of the NURBS-element, NC1 and NC2 in Figure 28-4 . |

"TRACT" Coordinate Card. Include this card if LTYPE = "TRACT." This card defines the traction load's coordinate system and loading direction.

| Card 1.1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

*LOAD

*LOAD_NURBS_SHELL

| VARIABLE | DESCRIPTION |
|----------|-------------|
|----------|-------------|

| | |
|---------------------------|---|
| RMIN, SMIN, RMAX, SMAX | The minimum and maximum values of the univariate knot vector in local r and s -directions of the area on which the pressure loading is applied. See *ELEMENT_SHELL_NURBS_PATCH for details. |
|---------------------------|---|

Region definition card when LTYPE = "PRESS" or LTYPE = "TRACT" and REGDEF = "NBEW". Define as many cards as needed.

| Card 2b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | NE1 | NE2 | NE3 | NE4 | NE5 | NE6 | NE7 | NE8 |
| Type | I | I | I | I | I | I | I | I |
| Default | none |

| VARIABLE | DESCRIPTION |
|----------|-------------|
|----------|-------------|

| | |
|--------|--|
| NE_i | An interior node on the surface of the NURBS element on which the traction loading is applied. |
|--------|--|

Region definition card when LTYPE = "PRESS" or LTYPE = "TRACT" and REGDEF = "NBEP". Define as many cards as needed.

| Card 2c | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|-----------|---|---|---|
| Variable | NT1 | NT2 | NT3 | NT4 | NTE | | | |
| Type | I | I | I | I | I | | | |
| Default | none | none | none | none | see below | | | |

| VARIABLE | DESCRIPTION |
|----------|-------------|
|----------|-------------|

| | |
|--------|---|
| NT_i | Nodes defining an area on the surface of a NURBS element where loading is applied. Using nodes shared with other NURBS elements, such as node NB in Figure 28-4 , as NT_i is not recommended. |
|--------|---|

| VARIABLE | DESCRIPTION |
|----------|--|
| NTE | Optional node used to identify the NURBS element on which the load application area defined by the NT <i>i</i> 's is located. NTE is <i>only</i> needed when <i>all</i> NT <i>i</i> 's are shared with other NURBS elements. If not defined, node NT1 has to be owned exclusively by the NURBS element containing the load application region. |

Region definition card for curve loading when LTYPE = "CRV", "CRVS", "CRVT", or "CRVN" and REGDEF = "RS". Define as many cards as needed.

| Card 2d | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|---|---|---|---|
| Variable | R1 | S1 | R2 | S2 | | | | |
| Type | F | F | F | F | | | | |
| Default | none | none | none | none | | | | |

| VARIABLE | DESCRIPTION |
|----------------|---|
| R1, S1, R2, S2 | The univariate knot vector in local <i>r</i> and <i>s</i> -directions of the starting and ending points of the curve on which the curve loading is applied. An example would be the knot vector for nodes NC1 and NC2 as shown in Figure 28-4 . |

Region definition card for curve loading when LTYPE = "CRV", "CRVS", "CRVT", or "CRVN" and REGDEF = "NBEP". Define as many cards as needed.

| Card 2e | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-----------|---|---|---|---|---|
| Variable | NC1 | NC2 | NCE | | | | | |
| Type | I | I | I | | | | | |
| Default | none | none | see below | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| NC i | Nodes defining a curve on the surface of a NURBS element where loading is applied. Using nodes shared with other NURBS elements, such as node NB in Figure 28-4 , as NC i is not recommended. |
| NCE | Optional node used to identify the NURBS element on which the load application curve defined by the NT i 's is located. NCE is <i>only</i> needed when <i>both</i> NC i 's are shared with other NURBS elements. If not defined, node NC1 has to be owned exclusively by the NURBS element containing the load application curve. |

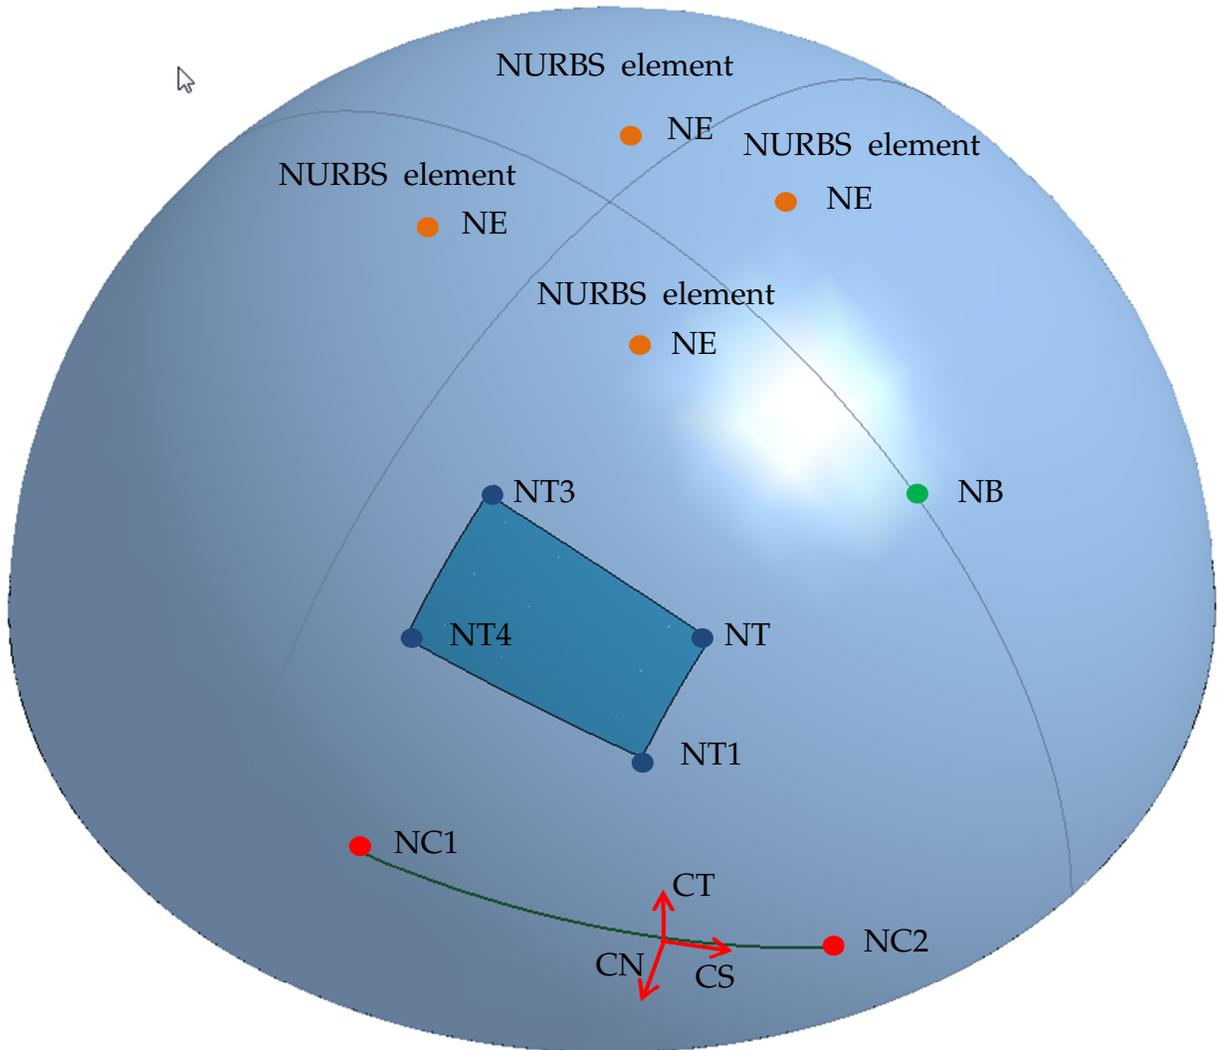

Figure 28-4. NURBS shell patch with four NURBS shell elements.

*LOAD

*LOAD_SEGMENT_SET

*LOAD_PZE

Purpose: Apply a concentrated or distributed electric charge over a set of segments or nodes with piezoelectric properties.

Include as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|------|------|-------|---|---|---|---|
| Variable | SETID | LCID | SF | SETYP | | | | |
| Type | I | I | F | A10 | | | | |
| Default | none | 0 | none | NSET | | | | |

VARIABLE

DESCRIPTION

| | |
|-------|---|
| SETID | Set ID; see *SET_SEGMENT or *SET_NODE. |
| LCID | Load curve gives concentrated charge (in electric charge units) or distributed electric charge (in unit of electric charge per unit area) vs. time. |
| SF | Scale factor on curve or constant electric charge if LCID = 0. |
| SETYP | Type of SETID EQ.NSET: SETID is a node set EQ.SEGSET: SETID is a segment set |

***LOAD_REMOVE_PART_{OPTION}**

Available options include:

<BLANK>

SET

Purpose: Delete the elements of a part in a staged construction simulation. Shock effects are prevented by gradually reducing the stresses prior to deletion. Available for solid, shell and beam elements.

Part Cards. Include as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|-------|-------|------|---|---|---|---|
| Variable | PID/PSID | TIME0 | TIME1 | STGR | | | | |
| Type | I | F | F | I | | | | |
| Default | none | 0 | 0 | 0 | | | | |

VARIABLE**DESCRIPTION**

| | |
|-------|---|
| PID | Part ID (or Part Set ID for the SET option) for deletion |
| TIME0 | Time at which stress reduction starts |
| TIME1 | Time at which stresses become zero and elements are deleted |
| STGR | Construction stage at which part is removed (optional) |

Remarks:

There are 3 methods of defining the part removal time:

1. TIME0, TIME1 override all the other methods if non-zero
2. STGR refers to the stage at which the part is removed – the stages are defined in *DEFINE_CONSTRUCTION_STAGES. This is equivalent to setting TIME0 and TIME1 equal to the start and end of the ramp time at the beginning of stage STGR.

3. *DEFINE_STAGED_CONSTRUCTION_PART can be used instead of *LOAD_REMOVE_PART to achieve the same effect.

***LOAD_RIGID_BODY**

Purpose: Apply a concentrated nodal force to a rigid body. The force is applied at the center of mass or a moment is applied around a global axis. As an option, local axes can be defined for force or moment directions.

Rigid Body Cards. Include as many Rigid Body Cards as necessary. This input ends at the next keyword (“*”) card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|----|--------|----|----|----|
| Variable | PID | DOF | LCID | SF | CID | M1 | M2 | M3 |
| Type | I | I | I | F | I | I | I | I |
| Default | none | none | none | 1. | global | 0 | 0 | 0 |

VARIABLE**DESCRIPTION**

| | |
|------|--|
| PID | Part ID of the rigid body; see *PART_OPTION. |
| DOF | Applicable degrees-of-freedom: EQ.1: x -direction of load action, EQ.2: y -direction of load action, EQ.3: z -direction of load action, EQ.4: follower force; see Remark 2, EQ.5: moment about the x -axis, EQ.6: moment about the y -axis, EQ.7: moment about the z -axis. EQ.8: follower moment; see Remark 2. |
| LCID | Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION and Remark 3). GT.0: force as a function of time. LT.0: force as a function of the absolute value of the rigid body displacement. This option only applies to load curves. |
| SF | Load curve scale factor |

***LOAD_SEGMENT_{OPTION}**

To define an ID for the segment loading, the following option is available:

ID

If the ID is defined, an additional card is required.

Purpose: Apply the distributed pressure load over one triangular or quadrilateral segment defined by four, six, or eight nodes, or in the case of two-dimensional geometries, over one two-noded line segment. The pressure and node numbering convention are specified in [Figure 28-5](#). To apply a uniform pressure, see [Remark 5](#).

ID Card. Additional card for the ID keyword option.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|---------|---|---|---|---|---|---|
| Variable | ID | HEADING | | | | | | |
| Type | I | A70 | | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|----|----|------|------|------|------|------|
| Variable | LCID | SF | AT | N1 | N2 | N3 | N4 | N5 |
| Type | I | F | F | I | I | I | I | I |
| Default | none | 1. | 0. | none | none | none | none | none |

Additional card for when $N5 \neq 0$.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|---|---|---|---|---|
| Variable | N6 | N7 | N8 | | | | | |
| Type | I | I | I | | | | | |
| Default | none | none | none | | | | | |

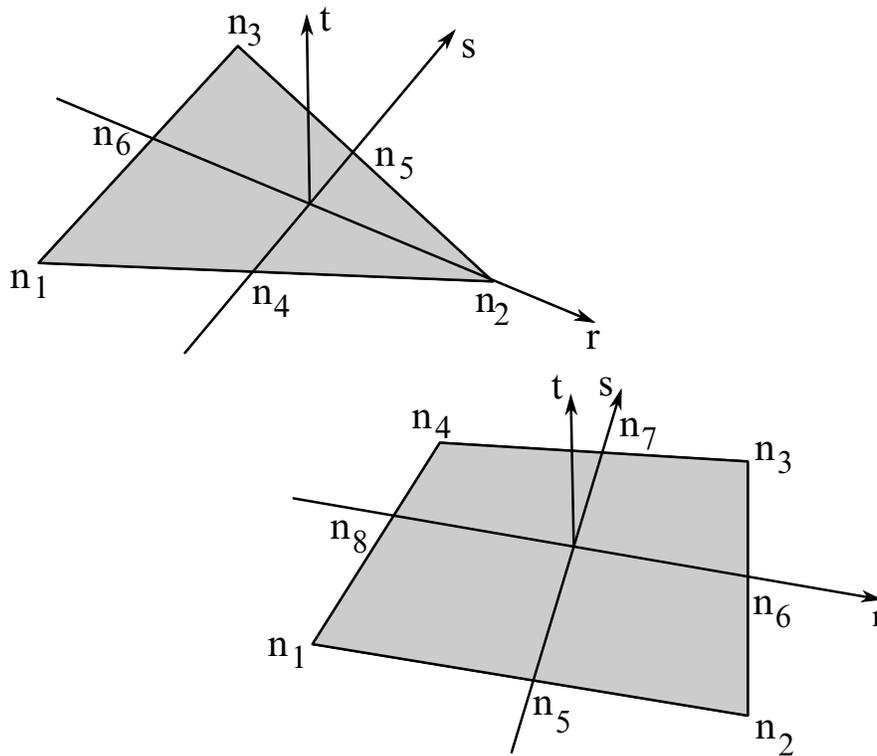

Figure 28-5. Nodal numbering for pressure segments in three-dimensional geometries. Positive pressure acts in the negative t -direction.

| VARIABLE | DESCRIPTION |
|----------|---|
| ID | Loading ID |
| HEADING | A description of the loading. |
| LCID | Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION). See Remark 1 . |
| SF | Load curve scale factor. See Remark 2 . |
| AT | Arrival time for pressure or birth time of pressure. See Remark 3 . |
| N1 | Node ID |
| N2 | Node ID |
| N3 | Node ID. See Remark 4 . |
| N4 | Node ID. See Remark 4 . |
| N5 | Mid-side node ID, if applicable. See Figure 28-5 . |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| N6 | Mid-side node ID, if applicable. See Figure 28-5 . |
| N7 | Mid-side node ID, if applicable. See Figure 28-5 . |
| N8 | Mid-side node ID, if applicable. See Figure 28-5 . |

Remarks:

1. **Empirical Functions for Pressure.** If LCID is input as -1, then the Brode function is used to determine the pressure for the segments; see *LOAD_BRODE. If LCID is input as -2, then an empirical airblast function is used to determine the pressure for the segments; see *LOAD_BLAST.
2. **Load Curve Multipliers.** The load curve multipliers may be used to increase or decrease the pressure. The time value is not scaled.
3. **Activation Time.** The activation time, AT, is the time during the solution that the pressure begins to act. Until this time, the pressure is ignored. The function value of the load curves will be evaluated at the offset time given by the difference of the solution time and AT, that is, solution time – AT.
4. **Triangular Segments and Two-Dimensional Geometries.** Triangular segments without mid-side nodes are defined by setting N4 = N3. Segments for two-dimensional geometries are defined by two nodes, N1 and N2. Leave N3 and N4 as zero or set both equal to N2. A positive pressure acts on the segment in the $\hat{z} \times (N1 - N2)$ direction where \hat{z} is the unit vector in the z-direction and $(N1 - N2)$ is the vector from N1 to N2.
5. **Uniform Pressure.** To apply a uniform pressure to type 17 tetrahedral elements, 4 triangular segments should be defined for each loaded face of an element. Three of the segments should each have one corner node and the two adjacent mid-side nodes. The 4th segment should be made from the 3 mid-side nodes.

To apply a uniform pressure to type 16 tetrahedral elements or type 24 triangular shell elements, one 6 node segment may be defined for each loaded face. However, LS-DYNA will accept and properly treat “any” other segment definition. In other words, if the preprocessor happens to create *one* 3-noded segment corresponding to local node numbering convention {1,2,3,3} in [Figure 28-5](#), or permutations thereof, then this will internally be detected as a 6-noded segment and the nodal forces will be consistently distributed over the 6 involved nodes. Likewise, if four 3-noded segments corresponding to local node numbering conventions {1,4,6,6}, {2,5,4,4}, {3,6,5,5} and {4,5,6,6}, or permuta-

***LOAD_SEGMENT_CONTACT_MASK**

Purpose: Mask the pressure from a *LOAD_SEGMENT_SET when the pressure segments are in contact with another material. For non-Mortar contact, this keyword is currently only supported in the MPP version, while Mortar contact is supported in all versions. Note that the Heading Card is required.

Heading Card.

| | | | | | | | | |
|----------|----|---------|---|---|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | ID | HEADING | | | | | | |
| Type | I | A70 | | | | | | |

Load Set Card.

| | | | | | | | | |
|----------|------|----|----|------|------|------|------|------|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | LSID | P1 | P2 | CID1 | CID2 | CID3 | CID4 | CID5 |
| Type | I | F | F | I | I | I | I | I |

Optional Cards. This data ends at the next "*" card.

| | | | | | | | | |
|----------|------|------|------|------|-------|--------|-------|-------|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | CID6 | CID7 | CID8 | CID9 | CID10 | CID11N | CID12 | CID13 |
| Type | I | I | I | I | I | I | I | I |

VARIABLE**DESCRIPTION**

| | |
|------|--|
| LSID | Load set ID to mask, which must match a *LOAD_SEGMENT_SET. See Remark 2 . |
| P1 | Lower pressure limit. When the surface pressure due to contact is below P1, no masking is done and the full load defined in *LOAD_SEGMENT_SET is applied. For pressures between P1 and P2 see Remark 1 . |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| P2 | Upper pressure limit. When the surface pressure due to contact is above P2, no load is applied due to the *LOAD_SEGMENT_SET. For pressures between P1 and P2 see Remark 1 . |
| CID n | <p>The IDs of contacts that can mask the pressure loads. The specified contact definitions must all be of the same type. Furthermore, only non-automatic SURFACE_TO_SURFACE (two way) or AUTOMATIC_SURFACE_TO_SURFACE_TIEBREAK are supported.</p> <p>For TIEBREAK contacts, pressure is masked until the tie fails. Once the tie fails, the full pressure will be applied for the remainder of the simulation. The values P1 and P2 are ignored.</p> <p>For other contact types, the contact forces, along with the nodal contact surface areas, are used to compute the contact pressure at each node to determine any masking effect.</p> |

Remarks:

1. **Intermediate Pressures.** If the contact pressure, p_{contact} is between P1 and P2, the pressure load is scaled by a factor of

$$f = \frac{P2 - p_{\text{contact}}}{P2 - P1}.$$

P1 may be set equal to P2 if desired.

2. **LSID.** The LSID values must be unique. Having two instances of this referencing the same *LOAD_SEGMENT_SET *is not supported*. However, a contact ID *may* appear in two different instances of this keyword.

LOAD**LOAD_SEGMENT_FILE*****LOAD_SEGMENT_FILE**

Purpose: To define *time-varying* distributed pressure loads over triangular or quadrilateral segments defined by four, six, or eight nodes using a *binary file*.

| | |
|----------|----------|
| Card 1 | 1 |
| Variable | FILENAME |
| Type | A80 |

Card 2 is required but may be left blank.

| | | | | | | | | |
|----------|------|---|---|---|---|---|---|---|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | LCID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|----------|--|
| FILENAME | Filename of binary database containing segment pressures as a function of time. There are three sections in this database. |
| LCID | Optional load curve ID defining segment pressure scale factor as a function of time. |

Remarks:

Each database is assumed to be written with a block size equal to a multiple of 512 words, with each block containing 1 or more states. If the data does not complete the last block, it is padded with zeros. The code will open and read the next family file if it detects a phony word or EOF. If the IO returns a zero length read, the code assumes end of IO and stops reading.

Linear interpolation is used if the IO can find the current time between two states. Therefore, the given database can have more states than simulation time steps.

Linear extrapolation will only be used when the IO reaches the end of the database. The last two states will be used and the warning message "MSG_SOL+1323" will be issued to the d3hsp and messag files.

| Section | Words | Description |
|--|--------|---|
| Control Section 64 words | 10 | Title |
| | 1 | NSEG: The absolute value, NSEG , specifies the number of segments contained within the file. If NSEG < 0, then the file contains mid-side nodes. |
| Segment Data 4 words | 1 | N1; Node ID. |
| | 1 | N2: Node ID. |
| | 1 | N3: Node ID. Repeat N2 for two-dimensional geometries. |
| | 1 | N4: Node ID. Repeat N2 for two-dimensional geometries or repeat N3 for 3-node triangular segments. |
| Mid-side Nodes 4 Words. Omitted unless NSEG < 0. | 1 | N5: Optional mid-side node ID. |
| | 1 | N6: Optional mid-side node ID. |
| | 1 | N7: Optional mid-side node ID. |
| | 1 | N8: Optional mid-side node ID. |

***LOAD_SEGMENT_FSILNK**

Purpose: Apply distributed pressure loads from a previous ALE analysis to a specified segment set in the current analysis. This capability trades some of the model’s accuracy for a large reduction in model size.

NOTE: The deck for the “previous” run must include a *DATABASE_BINARY_FSILNK card to activate the creation of the fsilink file. Either the *LOAD_SEGMENT_FSILNK card (this card) or the *DATABASE_BINARY_FSILNK card may be in an input deck, *but not both*.

| | | | | | | | | |
|----------|----------|---|---|---|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | FILENAME | | | | | | | |
| Type | A80 | | | | | | | |

| | | | | | | | | |
|----------|------|------|---|---|---|---|---|---|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | NINT | LCID | | | | | | |
| Type | I | I | | | | | | |
| Default | none | 0 | | | | | | |

Coupling ID Cards. Read in NINT coupling IDs. Repeat this card as many times as necessary to input all NINT values.

| | | | | | | | | |
|----------|------|------|-----|-----|-----|-----|-----|-----|
| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | ID1 | ID2 | ID3 | ID4 | ID5 | ID6 | ID7 | ID8 |
| Type | I | I | | | | | | |
| Default | none | none | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| FILENAME | Filename of the interface linking file. |
| NINT | Number of couplings for which the previous run provides pressure data. |
| LCID | Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION). The curve referred to by LCID provides a scale factor as a function of time. The pressure data that is read in from the fsilnk file is scaled according to this value. |
| IDI | These must match COUPIDs from the *CONSTRAINED_LAGRANGE_IN_SOLID card from the previous runs. These IDs specify which of the first run's couplings are propagated into this run through pressure data read from the fsilnk file. |

The algorithm:

This feature provides a method for using pressure time history data from *CONSTRAINED_LAGRANGE_IN_SOLID Lagrangian-to-ALE couplings in one calculation as pressure data for the same segment in subsequent calculations. The time range covered by the subsequent calculation *must* overlap the time range of the initial calculation.

First calculation: Write out pressure data.

1. Add a *DATABASE_BINARY_FSILNK card to the first run.
2. Specify filename for the fsilnk file by adding a command line argument to ls-dyna.

ls-dyna ... fsilnk=**fsi_filename** ...

Without a *DATABASE_BINARY_FSILNK card this command line argument will have no effect.

Format of fsilnk File:

WRITE: Job title (character*80 TITLE)

WRITE: Number of interfaces (integer NINTF)

For $i = 1$ to NINTF {

WRITE: Number of segments in the i^{th} interface (integer NSEG[i])

For $j = 1$ to NSEG[i] {

```
        WRITE: Connectivities of  $j^{\text{th}}$  segment in the  $i^{\text{th}}$  interface (integer*4)
    }
}
For  $n = 1$  to number of time steps {
    WRITE: time value for the  $n^{\text{th}}$  time step (real)
    For  $i = 1$  to NINTF
        For  $j = 1$  to NSEG[ $i$ ] {
            WRITE: Pressure for the  $j^{\text{th}}$  segment of the  $i^{\text{th}}$  interface (real)
        }
    }
}
```

Subsequent calculations: Read fsilnk File.

Include this keyword, *LOAD_SEGMENT_FSILNK, and be careful to remove the *DATABASE_BINARY_FSILNK keyword. Specify the name of the fsilnk file from the previous run on *LOAD_SEGMENT_FSILNK's first data card.

Then, at each time step, the pressure of the specified coupling IDs is set on the Lagrangian-mesh side from data in the fsilnk file. For times outside of the fsilnk file's range LS-DYNA extrapolates.

1. If current time is before the 1st fsilnk time, then pressure is set to 0.
2. If the current time is in the range of times in the fsilnk file, then the pressure is linearly interpolated from the data at the two time states in the fsilnk file bracketing the current time.
3. If the current time is after the last fsilnk time, then the pressure is set to the fsilnk pressure at last time step.

*LOAD

*LOAD_SEGMENT_NONUNIFORM

*LOAD_SEGMENT_NONUNIFORM_{OPTION}

To define an ID for the non-uniform segment loading the following option is available:

ID

If the ID option is used, an additional card is required.

Purpose: Apply a distributed load over one triangular or quadrilateral segment defined by three, four, six, or eight nodes. The loading and node numbering convention follows [Figure 28-3](#).

ID Card. Additional card for ID keyword option.

| Card ID | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|---------|---|---|---|---|---|---|
| Variable | ID | HEADING | | | | | | |
| Type | I | A70 | | | | | | |

Card Sets. Each segment is specified by a set of the following 3 cards. Include as many sets as necessary. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|----|----|--------|-----|------|------|------|
| Variable | LCID | SF | AT | DT | CID | V1 | V2 | V3 |
| Type | I | F | F | F | I | F | F | F |
| Default | none | 1. | 0. | 1.E+16 | 0 | none | none | none |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | N1 | N2 | N3 | N4 | N5 | N6 | N7 | N8 |
| Type | I | I | I | I | I | I | I | I |
| Default | none |

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | P1 | P2 | P3 | P4 | P5 | P6 | P7 | P8 |
| Type | F | F | F | F | F | F | F | F |
| Default | none |

VARIABLE**DESCRIPTION**

| | |
|------------|---|
| ID | Loading ID |
| HEADING | A description of the loading. |
| LCID | Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION). For a load curve ID the load curve must provide pressure as a function of time. For a function ID, the function is expected to have seven arguments: current time minus the birth time, the current x , y , and z coordinates, and the initial x , y , and z coordinates. LT.0: Applies to 3, 4, 6 and 8-noded segments. With this option the load becomes a follower load, meaning that the direction of the load is constant with respect to the local segment coordinate system. |
| SF | Load curve scale factor |
| AT | Arrival / birth time for the traction load. |
| DT | Death time for the traction load |
| CID | Coordinate system ID |
| V1, V2, V3 | Vector direction cosines relative to coordinate system CID defining the direction of the traction loading. Note that for $LCID < 0$ this vector rotates with the geometry of the segment. |
| N1 | Node ID |
| N2 | Node ID |
| N3 | Node ID. Repeat N2 for two-dimensional geometries. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| N4 | Node ID. Repeat N2 for two-dimensional geometries or repeat N3 for 3-node triangular segments. |
| N5 | Optional mid-side node ID (see Figure 28-5). |
| N6 | Optional mid-side node ID (see Figure 28-5). |
| N7 | Optional mid-side node ID (see Figure 28-5). |
| N8 | Optional mid-side node ID (see Figure 28-5). |
| P1 | Scale factor at node ID, N1. |
| P2 | Scale factor at node ID, N2. |
| P3 | Scale factor at node ID, N3. |
| P4 | Scale factor at node ID, N4. |
| P5 | Scale factor at node ID, N5. |
| P6 | Scale factor at node ID, N6. |
| P7 | Scale factor at node ID, N7. |
| P8 | Scale factor at node ID, N8. |

***LOAD_SEGMENT_SET_{OPTION}**

To define an ID for the segment loading, the following option is available:

ID

If the ID is defined, an additional card is required.

Purpose: Apply the distributed pressure load over each segment in a segment set. See *LOAD_SEGMENT for a description of the pressure sign convention and remarks on higher order segment definitions.

ID Card. Additional card for the ID keyword option.

| | | | | | | | | |
|----------|----|---------|---|---|---|---|---|---|
| Card ID | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | ID | HEADING | | | | | | |
| Type | I | A70 | | | | | | |

Segment Set Cards. Include as many segment set cards as necessary. This input ends at the next keyword ("*") card.

| | | | | | | | | |
|----------|------|------|----|----|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | SSID | LCID | SF | AT | | | | |
| Type | I | I | F | F | | | | |
| Default | none | none | 1. | 0. | | | | |
| Remarks | | 1 | 2 | 3 | | | | |

VARIABLE

DESCRIPTION

| | |
|------|---|
| SSID | Segment set ID, see *SET_SEGMENT. |
| LCID | Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION). For a load curve ID the load curve must provide pressure as a function of time. For a function ID the function is expected to have seven arguments: current time minus the birth time, the current <i>x</i> , <i>y</i> , and <i>z</i> coordinates, and the initial <i>x</i> , <i>y</i> , and <i>z</i> coordinates. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| SF | Load curve scale factor |
| AT | Arrival time for pressure or birth time of pressure. |

Remarks:

1. **Pressure Functions.** If LCID is input as -1, then the Brode function is used to determine pressure for the segment set; also see *LOAD_BRODE. If LCID is input as -2, then an empirical airblast function is used to determine the pressure for the segments; see *LOAD_BLAST.
2. **Load Curve Multipliers.** The load curve multipliers may be used to increase or decrease the pressure. The time value is not scaled.
3. **Activation Time.** The activation time, AT, is the time during the solution that the pressure begins to act. Until this time, the pressure is ignored. The function value of the load curves will be evaluated at the offset time given by the difference of the solution time and AT, that is, (solution time-AT).

***LOAD_SEGMENT_SET_ANGLE**

Purpose: Apply a traction load over a segment set that is dependent on the orientation of a vector. An example application is applying a pressure to a cylinder as a function of the crank angle in an automobile engine. The pressure and node numbering convention follows [Figure 28-5](#).

Card Sets. Include as many sets of Cards 1 and 2 as desired. This input ends at the next keyword (“*”) card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|-------|-------|-------|---|---|
| Variable | ID | IDSS | LCID | SCALE | IOPTP | IOPTD | | |
| Type | I | I | I | F | I | I | | |
| Default | none | none | none | 1. | 0 | 0 | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|---|---|---|---|
| Variable | N1 | N2 | NA | NI | | | | |
| Type | I | I | I | I | | | | |
| Default | none | none | none | none | | | | |

VARIABLE**DESCRIPTION**

| | |
|-------|--|
| ID | Loading ID |
| IDSS | Segment set ID. |
| LCID | Load curve or function ID defining the traction as a function of the angle. If IOPTP, defined below, is 0, define the abscissa between 0 and 2π radians or 0 and 360 degrees depending on IOPTD. |
| SCALE | Scale factor on value of the load curve or function. |
| IOPTP | Flag for periodicity of load curve LCID: EQ.0: Requires the load curve to be defined between 0 and 2π . |

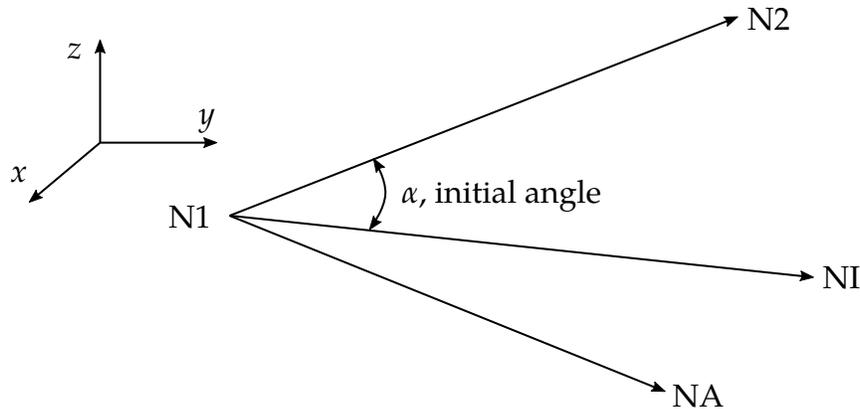

Figure 28-6. Orientation of rotating vector

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | <p>This is useful, for example, for modeling an engine that is running at a steady state since each rotation will experience the same loading.</p> <p>EQ.1: Load curve defined over the full range of angles for modeling a transient response. A different response is, therefore, permitted on the second and subsequent revolutions.</p> |
| IOPTD | <p>Flag for specifying angle units of the load curve LCID:</p> <p>EQ.0: Load curve or function argument is in radians.</p> <p>EQ.1: Load curve or function argument is in degrees.</p> |
| N1 | The node specifying the tail of the rotating vector. See Figure 28-6 . |
| N2 | The node specifying the head of the rotating vector. See Figure 28-6 . |
| NA | The node specifying the head of the vector defining the axis of rotation. The node N1 specifies the tail. See Figure 28-6 . |
| NI | The node specifying the orientation of the vector at an angle of zero. If the initial angle is zero, NI should be equal to N2. See Figure 28-6 . |

***LOAD_SEGMENT_SET_NONUNIFORM_{OPTION}**

To define an ID for the non-uniform segment loading the following option is available:

ID

If the ID is defined, an additional card is required.

Purpose: Apply the traction load over one triangular or quadrilateral segment defined by three or four nodes. The pressure and node numbering convention follows [Figure 28-5](#).

ID Card. Additional card for ID keyword option.

| Optional | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|---------|---|---|---|---|---|---|
| Variable | ID | HEADING | | | | | | |
| Type | I | A70 | | | | | | |

Card Sets. Include as many pairs of Cards 1 and 2 as desired. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|----|----|------------------|--------|---|---|
| Variable | SSID | LCID | SF | AT | DT | ELTYPE | | |

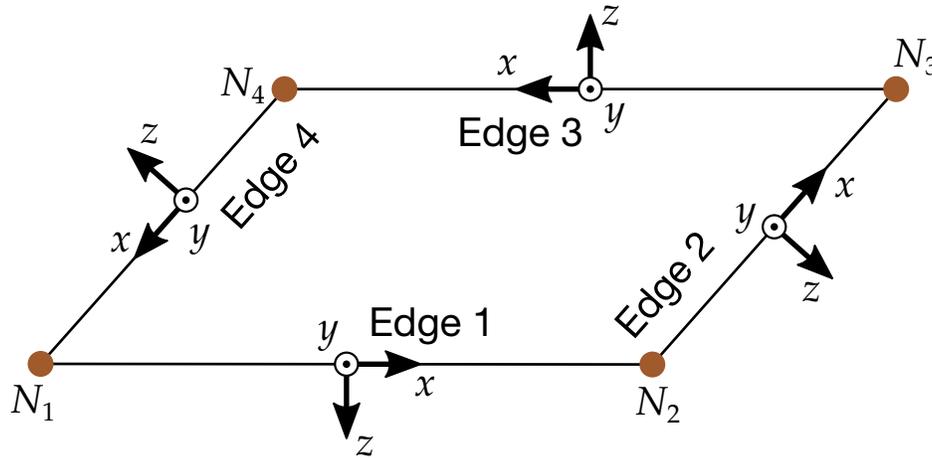

Figure 28-7. Local coordinates system for edge load.

| VARIABLE | DESCRIPTION |
|----------|--|
| ID | Loading ID |
| HEADING | A description of the loading. |
| SSID | Segment set ID. |
| LCID | Load curve ID (see *DEFINE_CURVE) or function ID (see *DEFINE_FUNCTION). The seven arguments for the function are current time minus the birth time, the current x , y , and z coordinates, and the initial x , y , and z coordinates. LT.0: Applies to 3, 4, 6 and 8-noded segment sets. With this option the load becomes a follower load, meaning that the direction of the load is constant with respect to the local segment coordinate system. The local coordinate system for edge load, see ELTYPE, is shown in Figure 28-7 . |
| SF | Load curve scale factor |
| AT | Arrival/birth time for pressure. |
| DT | Death time for pressure. |
| ELTYPE | Optional edge loading type. If left blank, pressure on the segment will be applied. EQ.EF1: Distributed force per unit length along edge 1, Figure 28-7 . EQ.EF2: Distributed force per unit length along edge 2, |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | Figure 28-7. |
| | EQ.EF3: Distributed force per unit length along edge 3, Figure 28-7. |
| | EQ.EF4: Distributed force per unit length along edge 4, Figure 28-7. |
| CID | Coordinate system ID |
| V1, V2, V3 | Vector direction cosines relative to the coordinate system CID defining the direction of the traction loading. Note that for $LCID < 0$ this vector rotates with the geometry of the segment. |

***LOAD_SEISMIC_SSI_OPTION1_{OPTION2}**

Available options for *OPTION1* include:

NODE

SET

POINT

OPTION2 allows an optional ID to be given:

ID

Purpose: Apply earthquake load due to free-field earthquake ground motion at certain locations — defined by either nodes or coordinates — on a soil-structure interface, for use in earthquake soil-structure interaction analysis. The specified motions are used to compute a set of effective forces in the soil elements adjacent to the soil-structure interface, according to the effective seismic input–domain reduction method [Bielak and Christiano (1984)].

Card Summary:

Card Sets. Include as many pairs of Card 1a or 1b (depending on keyword option) and Card 2 as desired. This input ends at the next keyword (“*”) card.

Card ID. This card is included if and only the ID keyword option is used.

| | |
|----|---------|
| ID | HEADING |
|----|---------|

Card 1a. This card is included if and only if the NODE or SET keyword option is used.

| | | | | | | | |
|------|--------|-----|-----|-----|--|--|--|
| SSID | TYPEID | GMX | GMY | GMZ | | | |
|------|--------|-----|-----|-----|--|--|--|

Card 1b. This card is included if and only if the POINT keyword option is used.

| | | | | | | |
|------|----|----|----|-----|-----|-----|
| SSID | XP | YP | ZP | GMX | GMY | GMZ |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| SSID | Soil-structure interface ID. |
| TYPEID | Node ID (NID in *NODE) or nodal set ID (SID in *SET_NODE). |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| XP | x coordinate of ground motion location on soil-structure interface. |
| YP | y coordinate of ground motion location on soil-structure interface. |
| ZP | z coordinate of ground motion location on soil-structure interface. |
| GMX | Acceleration load curve or ground motion ID for motion in the (local) x -direction. |
| GMY | Acceleration load curve or ground motion ID for motion in the (local) y -direction. |
| GMZ | Acceleration load curve or ground motion ID for motion in the (local) z -direction. |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|-----|-------|-----------|-----|-----|---|---|
| Variable | SF | CID | BIRTH | DEATH | ISG | IGM | | |
| Type | F | I | F | F | I | I | | |
| Default | 1. | 0 | 0. | 10^{28} | 0 | 0 | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| SF | Ground motion scale factor. |
| CID | Coordinate system ID, see *DEFINE_COORDINATE_SYSTEM. |
| BIRTH | Time at which specified ground motion is activated. |
| DEATH | Time at which specified ground motion is removed: EQ.0.0: default set to 10^{28} |

| VARIABLE | DESCRIPTION |
|----------|---|
| ISG | <p>Definition of soil-structure interface:</p> <p>EQ.0: SSID is ID for soil-structure interface defined by *INTERFACE_SSI_ID for non-matching mesh between soil and structure.</p> <p>EQ.1: SSID is the ID of the segment set on the soil side of the soil-structure interface. This segment set should be oriented toward the structure.</p> |
| IGM | <p>Specification of ground motions GMX, GMY, GMZ:</p> <p>EQ.0: ground motions are specified as acceleration load curves. See *DEFINE_CURVE</p> <p>EQ.1: Both ground accelerations and velocities specified using *DEFINE_GROUND_MOTION.</p> |

Remarks:

1. **Ground Motion at Soil-Structure Interface.** The ground motion at any node on a soil-structure interface is computed as follows:
 - a) If the node coincides with a location where ground motion is specified, that ground motion is used for that node.
 - b) If the node does not coincide with a location where ground motion is specified, the ground motion at that node along a particular degree-of-freedom is taken as a weighted average of all the ground motions specified on the interface along that degree-of-freedom, where the weights are inversely proportional to the distance of the node from the ground motion location.
2. **Multiple Ground Motions.** Multiple ground motions specified at the same location are added together to obtain the resultant ground motion at that location.
3. **Spatially-Uniform Ground Motion.** Spatially-uniform ground motion may be specified on a soil-structure interface by specifying the ground motion at only one location on that interface. Specifying the ground motion at more than one point on a soil-structure interface results in spatially-varying ground motion on that interface.

***LOAD_SHELL_OPTION1_{OPTION2}**

Available options for *OPTION1* include:

ELEMENT

SET

Available options for *OPTION2* include:

ID

If the ID is defined, an additional card is required.

Purpose: Apply the distributed pressure load over a single shell element or a shell element set. The numbering of the shell nodal connectivities must follow the right hand rule with positive pressure acting in the negative *t*-direction. See [Figure 28-5](#). This option applies to the three-dimensional shell elements only.

ID Card. Additional card for ID keyword option.

| Card ID | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|---------|---|---|---|---|---|---|
| Variable | ID | HEADING | | | | | | |
| Type | I | A70 | | | | | | |

Shell Cards. Include as many of these cards as desired. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|------|----|----|---|---|---|---|
| Variable | EID/ESID | LCID | SF | AT | | | | |
| Type | I | I | F | F | | | | |
| Default | none | none | 1. | 0. | | | | |

VARIABLE**DESCRIPTION**

EID/ESID

Shell ID (EID) or shell set ID (ESID), see *ELEMENT_SHELL or *SET_SHELL.

***LOAD_SPCFORC**

Purpose: When used in a full-deck restart run, this card will apply the SPC constraint forces from the initial run on the corresponding degrees of freedom in the current run. This is useful when modeling unbounded domains using a non-reflecting boundary while incorporating static stresses computed in the initial run: the fixed constraints on the outer boundary in the initial static analysis are removed in the transient analysis and replaced by equivalent static forces.

While *BOUNDARY_NON_REFLECTING acts similarly if dynamic relaxation is used for the static analysis, this approach works for any method used to preload the model.

No parameters are necessary for this card.

*LOAD

*LOAD_SSA

*LOAD_SSA

Purpose: The Sub-Sea Analysis (SSA) capability allows a simple and efficient way of loading the structure to account for the effects of the primary shock wave and the subsequent bubble oscillations of an underwater explosion. It achieves its efficiency by approximating the pressure scattered by air and water-backed plates and the pressure transmitted through a water-back plate. The loading incorporates the plane wave approximation for direct shock response and the virtual mass approximation for bubble response. *LOAD_SSA does not implement a doubly asymptotic approximation of transient fluid-structure interaction.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

| Variable | XS | YS | ZS | W | TDELY | RAD | CZ | |
| Type | F | F | F | F | F | F | F | |
| Default | none | none | none | none | none | none | none | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| VS | Sound speed in fluid |
| DS | Density of fluid |
| REFL | Consider reflections from sea floor. EQ.0: off EQ.1: on |
| ZB | Z coordinate of sea floor if REFL = 1, otherwise, not used. |
| ZSURF | Z coordinate of sea surface |
| FPSID | Part set ID of parts subject to flood control. See Remark 2 . Use the *SET_PART_COLUMN option where the parameters A1 and A2 must be defined as follows: Parameter A1: Flooding status: EQ.1.0: Fluid on both sides. EQ.2.0: Fluid outside, air inside. EQ.3.0: Air outside, fluid inside. EQ.4.0: Material or part is ignored. Parameter A2: Tubular outer diameter of beam elements. For shell elements this input must be greater than zero for loading. |
| PSID | Part set IDs of parts defining the wet surface. The elements defining these parts must have their outward normals pointing into the fluid. See Figure 28-8 . EQ.0: all parts are included. GT.0: the part set ID. |
| NPTS | Number of integration points for computing pressure (1 or 4) |
| A | Shock pressure parameter |
| ALPHA | α , shock pressure parameter |
| GAMMA | γ , time constant parameter |
| KTHETA | K_θ , time constant parameter |
| KAPPA | κ , ratio of specific heat capacities |

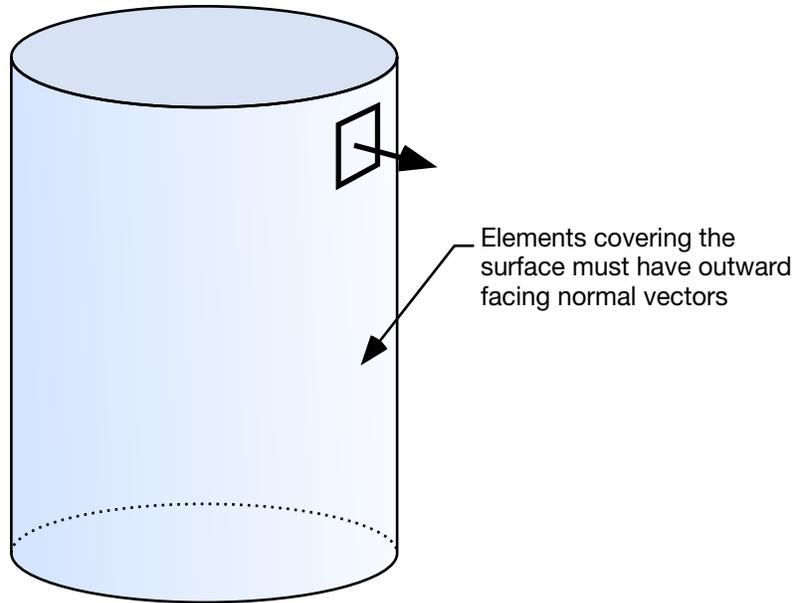

Figure 28-8. The shell elements interacting with the fluid must be numbered such that their outward normal vector points into the fluid media.

| VARIABLE | DESCRIPTION |
|----------|------------------------------------|
| XS | X coordinate of charge |
| YS | Y coordinate of charge |
| ZS | Z coordinate of charge |
| W | Weight of charge |
| TDELAY | Time delay before charge detonates |
| RAD | Charge radius |
| CZ | Charge depth |

Remarks:

1. **Units.** SSA assumes the model is in MKS units. If it is in another system of units, *CONTROL_COUPLING should be used to account for the conversion.
2. **Flooding Status.** The “flooding status” is instrumental in determining how the model parts are loaded. If A1 = 1.0, the front of the plate as defined by the outward normal is exposed to the incident pressure. The back of the plate is not exposed to the incident pressure but feels a transmitted pressure that re-

sists plate motion. If $A1 = 2.0$, then the plate has fluid on the outside as determined by the outward normal. It is exposed to the incident pressure and feels the scattered pressure. No loading is applied to the back side. If $A1 = 3.0$, then air is on the front of the plate and water is on the back. Neither the front nor the back of the plate is exposed to the incident pressure, but the motion of the plate is resisted by pressure generated on the back of the plate when it moves. Transmitted pressures are assumed not to strike another plate.

3. **Pressure History of Primary Shockwave.** The pressure history of the primary shockwave at a point in space through which a detonation wave passes is given as:

$$P(t) = P_m e^{-\frac{t}{\theta}}$$

where P_m and the time constant θ below are functions of the type and weight W of the explosive charge and the distance Q from the charge.

$$P_{peak} = A \left[\frac{W^{1/3}}{Q} \right]^\alpha$$
$$\theta = K_\theta W^{1/3} \left[\frac{W^{1/3}}{Q} \right]^\gamma$$

where A , α , γ , and K_θ are constants for the explosive being used.

*LOAD

*LOAD_STEADY_STATE_ROLLING

*LOAD_STEADY_STATE_ROLLING

Purpose: Steady state rolling analysis is a generalization of *LOAD_BODY, allowing the user to apply body loads to part sets due to translational and rotational accelerations in a manner that is more general than the *LOAD_BODY capability. *LOAD_STEADY_STATE_ROLLING may be invoked multiple times as long as no part has the command applied more than once. Furthermore, the command may be applied to arbitrary meshes, that is, axisymmetric meshes are not required.

Card Sets. Include as many sets consisting of the following four cards as desired. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|---|---|---|---|---|---|
| Variable | ID | PSID | | | | | | |
| Type | I | I | | | | | | |
| Default | none | none | | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|------|-------|---|---|---|---|
| Variable | N1 | N2 | LCD1 | LCD1R | | | | |
| Type | I | I | I | I | | | | |
| Default | 0 | 0 | 0 | LCD1 | | | | |

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|------|-------|---|---|---|---|
| Variable | N3 | N4 | LCD2 | LCD2R | | | | |
| Type 4 | I | I | I | I | | | | |
| Default | 0 | 0 | 0 | LCD2 | | | | |

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|------|-------|---|---|---|---|
| Variable | N5 | N6 | LCD3 | LCD3R | | | | |
| Type | I | I | I | I | | | | |
| Default | 0 | 0 | 0 | LCD3 | | | | |

VARIABLE**DESCRIPTION**

| | |
|-------|--|
| ID | ID |
| PSID | Part set ID |
| N1 | Node 1 defining rotational axis |
| N2 | Node 2 defining rotational axis |
| LCD1 | Load curve defining angular velocity around rotational axis. |
| LCD1R | Optional load curve defining angular velocity around rotational axis for dynamic relaxation. LCD1 is used during dynamic relaxation if LCD1R is not defined. |
| N3 | Node 3 defining turning axis |
| N4 | Node 4 defining turning axis |
| LCD2 | Load curve defining angular velocity around turning axis. |
| LCD2R | Optional load curve defining angular velocity around turning axis for dynamic relaxation. LCD2 is used during dynamic relaxation if LCD2R is not defined. |
| N5 | Node 5 defining translational direction |
| N6 | Node 6 defining translational direction |
| LCD3 | Load curve defining translational velocity in translational direction. |
| LCD3R | Optional load curve defining translational velocity in translational direction. LCD3 is used during dynamic relaxation if LCD3R is not defined. |

Remarks:

1. **Model.** The steady state rolling capability adds inertial body loads in terms of a moving reference defined by the user input. The current coordinates are defined in terms of the displacement, u , and the moving reference frame, Y ,

$$x_{SSR} = u + Y \quad \dot{x}_{SSR} = \dot{u} + \dot{Y} \quad \ddot{x}_{SSR} = \ddot{u} + \ddot{Y}$$

$$Y = R(\omega_2 t)[R(\omega_1 t)(X - X_O) - X_C] + Y_T(t)$$

where R is the rotation matrix obtained by integrating the appropriate angular velocity, the magnitude of the angular velocities ω_1 and ω_2 are defined by load curves LCD1 and LCD2 respectively, and the directions are defined by the current coordinates of the node pairs N1-N2 and N3-N4. The velocity corresponding to the translational term, $Y_T(t)$, is defined in magnitude by LCD3 and in direction by the node pair N5-N6. The initial coordinates of the nodes are X , X_O is the initial coordinate vector of node N1 and X_C is the initial coordinate vector of node N3. If data defining an angular velocity is not specified, the velocity is defaulted to zero, and R is the identity matrix. In a similar manner, if the translational velocity is not specified, it is defaulted to zero.

2. **Restrictions.** This capability is useful for initializing the stresses and velocity of tires during dynamic relaxation, and rolling processes in manufacturing. It is available for solid formulations 1, 2, 10, 13, and 15, and for shell formulations 2, 4, 5, 6, 16, 25, 26, and 27. It is not available for beams and tshells. It is available for implicit and explicit simulations and is invoked for dynamic relaxation by specifying that the load curves are used during dynamic relaxation. At the end of the dynamic relaxation, the velocities of the parts are set to \dot{x}_{SSR} and the remaining parts are initialized according to the input file.
3. **Convergence and Stability.** Users must ensure that the appropriate load curves are turned on during the relaxation process, and if implicit dynamic relaxation is used, that sufficient constraints are applied during the initialization to remove any rigid body motion and that they are removed at the end of the dynamic relaxation. The implicit iteration convergence rate is often improved by adding the geometric stiffness matrix using `*CONTROL_IMPLICIT_GENERAL`. A consistent tangent matrix is available by using `*CONTROL_IMPLICIT_GENERAL`, and while it improves the convergence rate with problems with small strains, it is often unstable for problems with large strains. The `*CONTROL_STEADY_STATE_ROLLING` options should be used to ramp up the frictional forces to obtain smooth solutions and good convergence rates.
4. **Angular Velocity and Hoop Strain.** To obtain the free-rolling angular velocity, the tire should be first inflated, then brought into contact with the road while the frictional force is ramped up with a load curve and a large value of `SCL_K` specified in `*CONTROL_STEADY_STATE_ROLLING`. The angular velocity of the tire is then slowly varied over a range that covers the free rolling

velocity. The free rolling velocity is obtained when either the frictional force in the direction of rolling or the moment about the tire axis is near zero. For a tire with an initial radius of R and a translational velocity of V , the approximate value for the free rolling value of the rolling velocity is

$$\omega = \frac{V}{(1 + \varepsilon)R} ,$$

where ε is the hoop strain of the rolling tire. For a first guess, the hoop strain can be set to 0.0, and the rolling velocity will be within 10% of the actual value. After the first calculation, a smaller range bracketing the free rolling velocity should be used in a second calculation to refine the free rolling velocity. An accurate value of the free rolling velocity is necessary for subsequent analyses, such as varying the slip angle of the tire.

5. **Slip Angle.** A time varying slip angle can be specified by moving one of the nodes defining the direction vector of the translational velocity. To check that the stiffness scale factor in *CONTROL_STEADY_STATE_ROLLING is high enough, a complete cycle from a zero slip angle to a maximum value, then back to zero, should be performed. If the loading and unloading values are reasonably close, then the stiffness scale factor is adequate.

***LOAD_STIFFEN_PART_{OPTION}**

Available options include:

<BLANK>

SET

Purpose: Staged construction. Available for solid, shell, and beam elements.

Construction Cards. Include as many of these cards as desired. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|----|---------|------|------|---|---|---|
| Variable | PID/PSID | LC | (blank) | STGA | STGR | | | |
| Type | I | I | | I | I | | | |
| Default | none | 0 | | 0 | 0 | | | |

VARIABLE**DESCRIPTION**

| | |
|------|--|
| PID | Part ID (or Part Set ID for the SET keyword option) |
| LC | Load curve defining factor as a function of time. See Remark 5 . |
| STGA | Construction stage at which part is added (optional) |
| STGR | Construction stage at which part is removed (optional) |

Remarks:

1. **Removing and Adding Parts.** For parts that are initially present but are removed during the analysis (for example, soil that is excavated), the stiffness factor starts at 1.0. Before the part is deleted, the stiffness factor should ramp down to a small value, such as 10^{-6} , over a duration long enough to avoid introducing shock or dynamic effects. The elements of a part introduced during the construction, such as retaining walls, are initially present in the model; however, the factor for this part is initially set to a low value, such as 10^{-6} . The stiffness factor increases to 1.0 when the part is added. A factor that increases from 10^{-6} to 1.0 and then reduces back to 10^{-6} can be used for temporary retaining walls, props, etc.

2. **Increasing and Decreasing Factor.** When the factor is increasing, it applies *only* to the stiffness and strength of the material in response to *subsequent* strain increments, not to any existing stresses. When the factor is decreasing, it applies to existing stresses as well as to the stiffness and strength.
3. **Compatible Material Models.** This feature works with all material models when used only to *reduce* the stiffness (e.g. parts that are excavated, not parts that are added during construction). When used to *increase* the stiffness from an initial low value, this feature works for most material types but not for hyperelastic types as well as certain others. There is no error check at present to detect STIFFEN_PART being used with an inappropriate material model. Symptoms of resulting problems would include non-physical large stresses when a part stiffens due to the accumulated strains in the “dormant” material since the start of the analysis.
4. **Gravity Factor.** This feature is generally used with *LOAD_GRAVITY_PART. The same curve is often used for the stiffness factor and the gravity factor.
5. **Factor Curve.** There are 3 methods for defining the factor as a function of time:
 - a) LC overrides STGA and STGR if LC is non-zero.
 - b) STGA and STGR refer to stages at which the part is added and removed: the stages are defined in *DEFINE_CONSTRUCTION_STAGES. If STGA is zero, the part has full stiffness at time zero. If not, it starts with a value equal to FACT (on *CONTROL_STAGED_CONSTRUCTION) and increases immediately to 1.0 at the start of stage STGA. If STGR is zero, the stiffness factor continues at 1.0 until the end of the analysis. If not, it ramps down from 1.0 to FACT over the ramp time at the start of stage STGR.
 - c) *DEFINE_STAGED_CONSTRUCTION_PART can be used instead of *LOAD_STIFFEN_PART to define this loading. During initialization, a *LOAD_STIFFEN_PART card will be created, and the effect is the same as using the STGA and STGR method described above. In many cases using *DEFINE_STAGED_CONSTRUCTION_PART is more convenient than this keyword.

***LOAD_SUPERPLASTIC_FORMING**

Purpose: Perform superplastic forming (SPF) analysis. This option can be applied to 2D and 3D solid elements and to 3D shell elements, and has been implemented for both explicit and implicit analyses. The pressure loading controlled by the load curve ID given below is scaled to maintain a constant maximal strain rate or other target value.

This option must be used with material model 64, *MAT_RATE_SENSITIVE_POWERLAW_PLASTICITY, for strain rate sensitive, powerlaw plasticity. For the output of data, see *DATABASE_SUPERPLASTIC_FORMING. Mass scaling is recommended in SPF applications.

New options to compute the target value with various averaging techniques and autojump options to control the simulation are implemented. Strain-rate speedup is also available. See [Remarks 5](#), [6](#), and [7](#) for details.

Card Sets. Include as many sets consisting of the following four cards as desired. This input ends at the next keyword ("*") card.

VARIABLE

DESCRIPTION

- LCP1 Load curve number for Phase I pressure loading; see *DEFINE_CURVE. The scaled version of this curve as calculated by LS-DYNA is output to curve1. See [Remark 3](#).
- CSP1 Contact surface number to determine completion of Phase I.
- NCP1 Percent of nodes in contact to terminate Phase I; see *CONTACT_OPTION.
- LCP2 Load curve number for Phase II pressure loading (reverse); see *DEFINE_CURVE. The scaled version of this curve as calculated by LS-DYNA is output to curve2. See [Remark 3](#).
- CSP2 Contact surface to determine completion of Phase II; see *CONTACT_OPTION.
- NCP2 Percent of nodes in contact to terminate Phase II.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| PCTS1 | Percentage of nodes-in-contact to active autojump in Phase I forming. |
| PCTS2 | Percentage of nodes-in-contact to active autojump in Phase II forming. |
| ERATE | Desired target value. If it's strain rate, this is the time derivative of the logarithmic strain. |
| SCMIN | Minimum allowable value for load curve scale factor. To maintain the target value, the pressure curve is scaled. In the case of a snap through buckling the pressure may be removed completely. By putting a value here the pressure will continue to act but at a value given by this scale factor multiplying the pressure curve. |
| SCMAX | Maximum allowable value for load curve scale factor. Generally, it is a good idea to put a value here to keep the pressure from going to unreasonable values after full contact has been attained. When full contact is achieved the strain rates will approach zero and pressure will go to infinity unless it is limited or the calculation terminates. |
| NCYL | Number of cycles for monotonic pressure after reversal. |
| NTGT | Type of the target (controlling) variable: EQ.1: strain rate. EQ.2: effective stress. |
| LEVEL | Criterion to compute averaged maximum of controlling variable: EQ.0: no average used. GE.1: averaging over neighbors of element with peak value of the controlling variable. This parameter determines the level of neighbor search. EQ.-1: averaging over elements within selective range of peak controlling variable. |
| TSRCH | Time interval to conduct neighbors search. |
| AT | Time when SPF Phase I simulation starts. |
| TPEAK | Additional run time to terminate simulation when maximum pressure is reached. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| TNEG | Additional run time to terminate simulation when percentage change of nodes-in-contact is zero or negative. |
| TOSC | Additional run time to terminate simulation when percentage change of nodes-in-contact oscillates within a specific value. |
| POSC | Percentage change to define the oscillation of percentage of nodes-in-contact. |
| PDROP | Drop in percentage of nodes-in-contact from the maximum to terminate simulation after the specified termination percentage has been reached. |
| STR | Autojump option or strike-through time (period of time without autojump check): EQ.0: no autojump EQ.-1: autojump controlled by peak pressure EQ.-2: autojump controlled by percentage of nodes in contact EQ.-3: autojump controlled by both above GT.0: strike-through time, then same as STR = -3 |
| THRES | Threshold percentage that gives the threshold value above which elements are considered for average. |
| LOWER | Lower percentile of elements above the threshold value to be included for average. |
| UPPER | Upper percentile of elements above the threshold value to be included for average. |
| RILIM | Maximum percentage change for pressure increment. |
| RDLIM | Maximum percentage change for pressure decrement. |
| TFACT | Strain rate speedup factor. |
| NTFCT | Number of computing cycles to ramp up speedup. |
| BOX | Box ID or Box Set ID. See Remark 8 . GT.0: Box ID; see *DEFINE_BOX. LT.0: BOX is box set ID; see *SET_BOX. |

Remarks:

1. **Second Phase.** Optionally, a second phase can be defined. In this second phase a *unique* set of pressure segments must be defined whose pressure is controlled by LCP2. During the first phase, the pressure segments of LCP2 are inactive, and likewise, during the second phase the pressure segments of the first phase are inactive. When shell elements are used, the complete set of pressure segments can be repeated in the input with a sign reversal used on the load curve. When solid elements are used, the pressure segments for each phase, in general, must be unique.
2. **NCYCL.** This is an ad hoc parameter which should probably not be used.
3. **Output Files.** There are three output files `pressure`, `curve1`, and `curve2` from the SPF simulation, and they may be plotted using ASCII → `superpl` in LS-PrePost. The file `curve2` is created only if the second phase is active. The time interval for writing out these files is controlled by `*DATABASE_SUPERPLASTIC_FORMING`. The files `curve1` and `curve2` contain the adjusted pressure histories calculated by SPF solver. The file `pressure` contains time histories of scaling factor, maximal target value, averaged target value, and percentage of contact.
4. **Contact.** The constraint method `contact`, `*CONTACT_CONSTRAINT_NODES_TO_SURFACE`, is recommended for superplastic forming simulations since the penalty methods are not as reliable when mass scaling is applied. Generally, in superplastic simulations mass scaling is used to enable the calculation to be carried out in real time.
5. **Averaging Algorithms.** In order to reduce the oscillation in pressure, the maximal target value used to adjust the pressure load is calculated by a special averaging algorithm. There are two options available:
 - a) *Averaging over neighbors of element with maximum target value:* In this method, the element that has the maximum strain rate or other controlling variable is stored in each cycle of the computation. The elements close to the element with the maximum value are searched and stored in an array. The averaged maximal target value is computed over the neighboring elements. The user can input an integer number to control the level of neighbor search, which will affect the total number of elements for average. Because the neighbor search is time consuming, the user can input a time interval to limit the occurrence of searching. The neighbor search is conducted only when the simulation time reaches the specified time or the element with maximum target value falls out of the array of neighbors.
 - b) *Averaging over elements within selective range of target value:* In this method, all elements that have target value above a threshold value (a threshold

percentage of maximum target value) are sorted according to their target value, and the elements between the user specified lower percentile and upper percentile are selected to compute the average of the maximal target value.

6. **Autojump.** The SPF simulation can be controlled by various autojump options. When autojump conditions are met, the SPF simulation will be either terminated or continued from phase I to phase II simulation. The autojump check can be held inactive by setting a strikethrough time. In this case the SPF simulation will continue for that period of time and only be interrupted when the percentage of nodes-in-contact reaches 100% for a specified time. The available autojump conditions are:
 - a) *Peak pressure is reached and stays for certain time:* The peak pressure is determined by the maximum allowable scale factor and the load curve. The simulation will continue for a user specified time before termination.
 - b) *User specified percentage of nodes-in-contact is reached:* The simulation will be terminated or continued to Phase II automatically if one of the following conditions is met:
 - i) If the change of the percentage of nodes-in-contact is zero or negative for a specified time.
 - ii) If the percentage of nodes-in-contact oscillates in a specified range for a specified time.
 - iii) If the percentage of nodes-in-contact drops more than a specified value from the maximum value recorded.
 - iv) If the percentage of nodes-in-contact reaches a user specified stop value.
7. **Computation Time.** In order to speed up the simulation of the superplastic forming process, we scale down the computation time. By doing this we increase the strain rate allowed in the SPF process, resulting in reduced simulation time. However, caution should be utilized with this speedup as it may affect the accuracy of the results. We recommend no or small strain rate speedup for simulations with complex geometry or tight angles.
8. **Critical Regions.** If the user knows the area(s) in the workpiece that are critical in the SPF process, he can use the box option to limit the region(s) where the elements are checked for computing the average of the maximal target value.

*LOAD

*LOAD_SURFACE_STRESS

*LOAD_SURFACE_STRESS_{OPTION}

Available options include:

<BLANK>

SET

Purpose: This keyword modifies the behavior of shell elements causing them to pass pressure-type loads to material models 37 and 125 (see [Remarks 1](#) and [2](#)); shells usually omit such effects.

With this keyword, LS-DYNA calculates segment pressures from contact and applied pressure loads on both the upper and lower surfaces of the shell and applies them as negative local z-stresses during the simulation. It is found in some cases this capability can improve the accuracy of metal forming simulations.

Card Sets. Include as many sets consisting of the following three cards as desired. This input ends at the next keyword (“*”) card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|---|---|---|---|---|---|---|
| Variable | PID/PSID | | | | | | | |
| Type | I | | | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|--------|--------|--------|--------|--------|--------|
| Variable | LSCID1 | LSCID2 | LSCID3 | LSCID4 | LSCID5 | LSCID6 | LSCID7 | LSCID8 |
| Type | I | I | I | I | I | I | I | I |

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|--------|--------|--------|--------|--------|--------|
| Variable | USCID1 | USCID2 | USCID3 | USCID4 | USCID5 | USCID6 | USCID7 | USCID8 |
| Type | I | I | I | I | I | I | I | I |

| VARIABLE | DESCRIPTION |
|-----------|--|
| PID/PSID | Part ID or, if option SET is active, part set ID. |
| LSCID n | <p data-bbox="475 331 1409 527">Lower surface contact IDs. Up to eight IDs can be defined. These contacts definitions contribute to the pressure acting on the lower surface of the shell. If the pressure on the lower surface is due to applied pressure loads, specify a value -1 instead of a contact ID. Only one of the LSCIDn may be set to -1.</p> <p data-bbox="475 537 1409 611">Lower surface of a part is on the opposite side of the shell element normals, which must be made consistent (in LS-PrePost).</p> |
| USCID n | <p data-bbox="475 638 1409 833">Upper surface contact IDs. Up to eight IDs can be defined. These contacts definitions contribute to the pressure acting on the upper surface of the shell. If the pressure on the upper surface is due to applied pressure loads, specify a value of -1 instead of a contact ID. Only one of the USCIDn may be set to -1.</p> <p data-bbox="475 844 1409 913">Upper surface of a part is on the same side of the shell element normals, which must be made consistent (in LS-PrePost).</p> |

Remarks:

1. **MAT_TRANSVERSLY_ANISOTROPIC_ELASTIC_PLASTIC (37).** This keyword can be used with *MAT_037 when ETAN is set to a negative value (see *MAT_037 manual pages), which triggers normal stresses (local z-stresses) resulting either from sliding contact or applied pressure to be considered in the shell formulation. The normal stresses can be significant in male die radius and corners in forming of Advanced High Strength Steels (AHSS). The negative local z-stresses are written to the d3plot files after Revision 97158 and can be plotted in LS-PrePost by selecting z-stress under *FCOMP* → *Stress* and select *local* under *FCOMP*.
2. **MAT_KINEMATIC_HARDENING_TRANSVERSLY_ANISOTROPIC (125).** This keyword can also be used in a simulation with *MAT_125 to account for the normal stresses (see *MAT_125 manual pages). For this material inserting this keyword *anywhere* in the input deck will invoke the shell normal stress calculation.

***LOAD_THERMAL_OPTION**

Available options include:

CONSTANT
CONSTANT_ELEMENT_OPTION
CONSTANT_NODE
LOAD_CURVE
TOPAZ
VARIABLE
VARIABLE_ELEMENT_OPTION
VARIABLE_NODE
VARIABLE_SHELL_OPTION

Purpose: To define nodal temperatures that thermally load the structure. Nodal temperatures defined by the **LOAD_THERMAL_OPTION* method are all applied in a structural only analysis. They are ignored in a thermal only or coupled thermal/structural analysis, see **CONTROL_THERMAL_OPTION*.

All the **LOAD_THERMAL* options cannot be used in conjunction with each other. Only those of the same thermal load type, as defined below in column 2, may be used together.

| | |
|---------------------------------------|-----------------------|
| <i>*LOAD_THERMAL_CONSTANT</i> | - Thermal load type 1 |
| <i>*LOAD_THERMAL_ELEMENT</i> | - Thermal load type 1 |
| <i>*LOAD_THERMAL_CONSTANT_NODE</i> | - Thermal load type 1 |
| <i>*LOAD_THERMAL_LOAD_CURVE</i> | - Thermal load type 2 |
| <i>*LOAD_THERMAL_TOPAZ</i> | - Thermal load type 3 |
| <i>*LOAD_THERMAL_VARIABLE</i> | - Thermal load type 4 |
| <i>*LOAD_THERMAL_VARIABLE_ELEMENT</i> | - Thermal load type 4 |
| <i>*LOAD_THERMAL_VARIABLE_NODE</i> | - Thermal load type 4 |
| <i>*LOAD_THERMAL_VARIABLE_SHELL</i> | - Thermal load type 4 |

***LOAD_THERMAL_CONSTANT**

Purpose: Define the constant temperature that is applied to a given nodal set. The reference temperature state is assumed to be a null state with this option. A nodal temperature state, read in and held constant throughout the analysis, dynamically loads the structure. Thus, the temperature defined can also be seen as a relative temperature to a surrounding or initial temperature.

Card Sets. Include as many sets consisting of the following two cards as desired. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|--------|-------|---|---|---|---|---|
| Variable | NSID | NSIDEX | BOXID | | | | | |
| Type | I | I | I | | | | | |
| Default | {all} | 0 | 0 | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|---|---|---|---|---|---|
| Variable | T | TE | | | | | | |
| Type | F | F | | | | | | |
| Default | 0. | 0. | | | | | | |

VARIABLE**DESCRIPTION**

NSID

Nodal set ID containing nodes for initial temperature

EQ.0: all nodes are included

NSIDEX

Nodal set ID containing nodes that are exempted from the imposed temperature (optional).

BOXID

All nodes in box which belong to NSID are initialized. Others are excluded (optional).

T

Temperature

*LOAD

*LOAD_THERMAL_CONSTANT

| VARIABLE | DESCRIPTION |
|----------|--|
| TE | Temperature of exempted nodes (optional) |

*LOAD_THERMAL_CONSTANT_ELEMENT_OPTION

Available options include:

- BEAM
- SHELL
- SOLID
- TSHELL

Purpose: Define a uniform element temperature that remains constant for the duration of the calculation. The reference temperature state is assumed to be a null state. An element temperature, read in and held constant throughout the analysis, dynamically loads the structure. The defined temperature can also be seen as a relative temperature to a surrounding or initial temperature.

Element Cards. Include as many cards in this format as desired. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|----|---|---|---|---|---|---|
| Variable | EID | T | | | | | | |
| Type | I | F | | | | | | |
| Default | none | 0. | | | | | | |

| <u>VARIABLE</u> | <u>DESCRIPTION</u> |
|-----------------|---|
| EID | Element ID |
| T | Temperature, see Remark 1 . |

Remarks:

1. **Reference Temperature.** The temperature range for the constitutive constants in the thermal materials must include the reference temperature of zero. If not, termination will occur with a temperature out-of-range error immediately after the execution phase is entered.

*LOAD

*LOAD_THERMAL_CONSTANT_NODE

*LOAD_THERMAL_CONSTANT_NODE

Purpose: Define nodal temperature that remains constant for the duration of the calculation. The reference temperature state is assumed to be a null state with this option. A nodal temperature state, read in and held constant throughout the analysis, dynamically loads the structure. Thus, the temperature defined can also be seen as a relative temperature to a surrounding or initial temperature.

Node Cards. Include as many cards in this format as desired. This input ends at the next keyword ("*") card.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|----|---|---|---|---|---|---|
| Variable | NID | T | | | | | | |
| Type | I | F | | | | | | |
| Default | none | 0. | | | | | | |

VARIABLE

DESCRIPTION

| | |
|-----|---|
| NID | Node ID |
| T | Temperature, see Remark 1 . |

Remarks:

1. **Reference Temperature.** The temperature range for the constitutive constants in the thermal materials must include the reference temperature of zero. If not, termination will occur with a temperature out-of-range error immediately after the execution phase is entered.

***LOAD_THERMAL_D3PLOT**

Purpose: Temperatures computed in a prior thermal-only analysis are used to load a mechanical-only analysis. The rootname of the d3plot database from the thermal-only analysis is specified on the execution line of the mechanical-only analysis using `T = tpf`, where `tpf` is that rootname, such as `T = d3plot`.

Warnings:

1. If using a double precision LS-DYNA executable in making the two runs, do not write the d3plot data using 32ieee format in the thermal-only run, that is, the environment variable `LSTC_BINARY` must not be set.
2. The rootnames of the d3plot databases from the two runs must not conflict. Such conflict can be avoided, for example, by using `jobid = jobname` on the execution line of the second (mechanical-only) run.

*LOAD

*LOAD_THERMAL_LOAD_CURVE

*LOAD_THERMAL_LOAD_CURVE

Purpose: Nodal temperatures will be uniform throughout the model and will vary according to a load curve. The temperature at time = 0 becomes the reference temperature for the thermal material. The reference temperature is obtained from the optional curve for dynamic relaxation if this curve is used. The load curve option for dynamic relaxation is useful for initializing preloads.

Thermal Load Curve Cards. Include as many cards in this format as desired. This input ends at the next keyword (“*”) card.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|---|---|---|---|---|---|
| Variable | LCID | LCIDDR | | | | | | |
| Type | I | I | | | | | | |
| Default | none | 0 | | | | | | |

VARIABLE

DESCRIPTION

LCID Load curve ID, see *DEFINE_CURVE, to define temperature as a function of time.

LCIDDR An optional load curve ID, see *DEFINE_CURVE, to define temperature as a function of time during the dynamic relaxation phase.

***LOAD_THERMAL_TOPAZ**

Purpose: Nodal temperatures will be read in from the TOPAZ3D database. This file is defined on the execution line by the specification: T = tpf, where tpf is a binary database file (e.g., T3PLOT).

*LOAD

*LOAD_THERMAL_VARIABLE

*LOAD_THERMAL_VARIABLE

Purpose: Define nodal temperature using node set(s) and temperature as a function of time curve(s).

Card Sets. Include as many sets consisting of the following two cards as desired. This input ends at the next keyword ("**") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|--------|-------|---|---|---|---|---|
| Variable | NSID | NSIDEX | BOXID | | | | | |
| Type | I | I | I | | | | | |
| Default | {all} | {∅} | 0 | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|------|-----|-----|-------|-------|---------|
| Variable | TS | TB | LCID | TSE | TBE | LCIDE | LCIDR | LCIDEDR |
| Type | F | F | I | F | F | I | I | I |
| Default | 0. | 0. | none | 0. | 0. | ↓ | none | ↓ |
| Remark | 1 | 1 | 1 | 1 | 1 | | | |

VARIABLE

DESCRIPTION

| | |
|--------|--|
| NSID | Nodal set ID containing nodes (see *SET_NODE_OPTION): EQ.0: all nodes are included. |
| NSIDEX | Nodal set ID containing nodes that are exempted (optional), (see *SET_NODE_OPTION). |
| BOXID | All nodes in box which belong to NSID are initialized. Others are excluded. |
| TS | Scaled temperature. |
| TB | Base temperature. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| LCID | Load curve ID that multiplies the scaled temperature, (see *DEFINE_CURVE). |
| TSE | Scaled temperature of the exempted nodes (optional). |
| TBE | Base temperature of the exempted nodes (optional). |
| LCIDE | Load curve ID that multiplies the scaled temperature of the exempted nodes (optional), (see *DEFINE_CURVE). |
| LCIDR | Load curve ID that multiplies the scaled temperature during the dynamic relaxation phase |
| LCIDEDR | Load curve ID that multiplies the scaled temperature of the exempted nodes (optional) during the dynamic relaxation phase. |

Remarks:

1. **Temperature Model.** The total temperature is defined as

$$T = TB + TS \times f(t) ,$$

where $f(t)$ is the current value of the load curve, TS is the scaled temperature, and TB is the base temperature.

2. **Thermal Strain.** The rate of thermal strain is based on the rate of temperature change. In other words, the thermal load arises from change in total temperature. Furthermore, the calculation of the thermal strain from the coefficient of thermal expansion depends on the material model, and some material models, e.g., *MAT_255, may offer multiple options. Temperature-dependent material properties are based on the total temperature.

*LOAD

*LOAD_THERMAL_VARIABLE_BEAM

*LOAD_THERMAL_VARIABLE_BEAM_{OPTION}

Available options include:

<BLANK>

SET

Purpose: Define a known temperature time history as a function of the section coordinates for beam elements. To set the temperature for the whole element see *LOAD_THERMAL_VARIABLE_ELEMENT_BEAM.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---------|--------|---|---|---|---|---|
| Variable | ID | EID/SID | IPOLAR | | | | | |
| Type | I | I | I | | | | | |
| Default | none | none | 0 | | | | | |

Temperature Cards. Include as many cards in the following format as desired. See [Remarks 2](#) and [3](#). This input ends at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|--------|--------|--------|-------|-------|---|---|
| Variable | TBASE | TSCALE | TCURVE | TCURDR | SCOOR | TCOOR | | |
| Type | F | F | I | I | F | F | | |
| Default | 0. | 1.0 | 0 | TCURVE | none | none | | |

VARIABLE

DESCRIPTION

| | |
|---------|---|
| ID | Load case ID |
| EID/SID | Beam ID or beam set ID |
| IPOLAR | Flag to use polar coordinates instead of rectangular coordinates. GT.0: The coordinates SCOOR and TCOOR are given in polar coordinates. See Remark 3 . |
| TBASE | Base temperature |

| VARIABLE | DESCRIPTION |
|----------|-------------|
|----------|-------------|

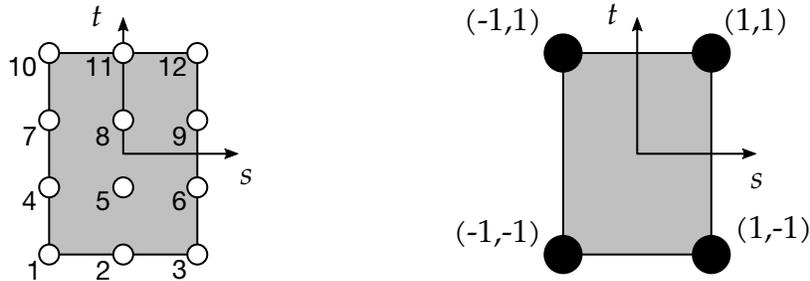

Figure 0-1. Figure illustrating point ordering.

| | |
|--------|---|
| TSCALE | Constant scale factor applied to temperature from curve |
| TCURVE | Curve ID for temperature as a function of time |
| TCURDR | Curve ID for temperature as a function of time used during dynamic relaxation |
| SCOOR | Normalized coordinate in local s -direction (-1.0 to +1.0) |
| TCOOR | Normalized coordinate in local t -direction (-1.0 to +1.0) |

Remarks:

1. **Temperature Curve.** The temperature T is defined as:

$$T = TBASE + TSCALE \times f(t)$$

where $f(t)$ is the current ordinate value of the curve. If the curve is undefined, then $T = TBASE$ at all times.

2. **Cross Section Coordinates.** At least four points (four Card 2's) must be defined in a rectangular grid since each edge can have a different temperature history. The required order of the points is as shown in [Figure 0-1](#). First, define the bottom row of points (most negative t), left to right in order of increasing s . Then increment t to define the next row of points, left-to-right in order of increasing s , and so on. The s - t axes are in the plane of the beam cross-section with the s -axis in the plane of nodes N1, N2, N3 defined in *ELEMENT_BEAM.
3. **Polar Cross Section Coordinates.** For this option only two points (two Card 2's) must be defined for the center and edge of the section because the temperature changes are assumed to only be in the radial direction. For the polar option, SCOOR is the non-dimensional radius R/R_0 where R_0 is the outer radius

of the section; and TCOOR is defined as θ/π , where θ is the angle in radians from the s -axis and ranges from $-\pi$ to π .

4. **Integration Point Temperatures.** Temperatures will be assigned to the integration points by linear interpolation from the points defined using this command.

***LOAD_THERMAL_VARIABLE_ELEMENT_OPTION**

Available options include:

- BEAM
- SHELL
- SOLID
- TSHELL

Purpose: Define element temperature that is variable during the calculation. The reference temperature state is assumed to be the temperature at time = 0.0 with this option.

Element Cards. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|----|----|------|---|---|---|---|
| Variable | EID | TS | TB | LCID | | | | |
| Type | I | F | F | I | | | | |
| Default | none | 0. | 0. | none | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| EID | Element ID |
| TS | Scaled temperature |
| TB | Base temperature |
| LCID | Load curve ID defining a scale factor that multiplies the scaled temperature as a function of time (see *DEFINE_CURVE). |

Remarks:

1. The temperature is defined as:

$$T = TB + TS \times f(t)$$

where $f(t)$ is the current value of the load curve, TS is the scaled temperature, and TB is the base temperature

*LOAD

*LOAD_THERMAL_VARIABLE_NODE

*LOAD_THERMAL_VARIABLE_NODE

Purpose: Define nodal temperature that is variable during the calculation. The reference temperature state is assumed to be a null state with this option. A nodal temperature state read in and varied according to the load curve dynamically loads the structure. Thus, the defined temperatures are relative temperatures to an initial reference temperature.

Node Cards. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|----|----|------|---|---|---|---|
| Variable | NID | TS | TB | LCID | | | | |
| Type | I | F | F | I | | | | |
| Default | none | 0. | 0. | none | | | | |

| <u>VARIABLE</u> | <u>DESCRIPTION</u> |
|-----------------|--|
| NID | Node ID |
| TS | Scaled temperature |
| TB | Base temperature |
| LCID | Load curve ID that multiplies the scaled temperature, (see *DEFINE_CURVE). |

Remarks:

1. The temperature is defined as:

$$T = TB + TS \times f(t)$$

where $f(t)$ is the current value of the load curve, TS is the scaled temperature, and TB is the base temperature

***LOAD_THERMAL_VARIABLE_SHELL_{OPTION}**

Available options include:

<BLANK>

SET

Purpose: Define a known temperature time history as a function of the through-thickness coordinate for the shell elements.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---------|---|---|---|---|---|---|
| Variable | ID | EID/SID | | | | | | |
| Type | I | I | | | | | | |
| Default | none | none | | | | | | |

Temperature Cards. Include as many cards of this type as desired. This input ends at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|--------|--------|--------|------|---|---|---|
| Variable | TBASE | TSCALE | TCURVE | TCURDR | ZCO | | | |
| Type | F | F | I | I | F | | | |
| Default | 0.0 | 1.0 | Rem 1 | TCURVE | none | | | |

| <u>VARIABLE</u> | <u>DESCRIPTION</u> |
|-----------------|---|
| ID | Load case ID |
| EID/SID | Shell ID or shell set ID |
| TBASE | Base temperature |
| TSCALE | Constant scale factor applied to temperature from curve |
| TCURVE | Curve ID for temperature as a function of time |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| TCURDR | Curve ID for temperature as a function of time used during dynamic relaxation |
| ZCO | Normalized through-thickness coordinate (-1.0 to +1.0). See Remarks 2 and 3 . |

Remarks:

1. **Temperature Definition.** The temperature T is defined as:

$$T = TBASE + TSCALE \times f(t) ,$$

where $f(t)$ is the current ordinate value of the curve. If the curve is undefined, then $T = TBASE$ at all times.

2. **Through-Thickness Coordinate.** Through-thickness points must be defined in order of increasing ZCO (-1.0 to +1.0). ZCO = +1.0 is the top surface of the element, that is, the element surface in the positive outward normal vector direction from the mid-plane.
3. **Shell Temperature Distribution.** At least two points (two Card 2's) must be defined. Temperatures will be assigned in the through-thickness direction by linear interpolation from the points defined using this command. If the element has multiple in-plane integration points, the same temperature distribution is used at each in-plane integration point.
4. **LOAD_THERMAL_NODE.** If a shell's temperature distribution is defined using this card, any values defined by *LOAD_THERMAL_NODE are ignored for that shell.

***LOAD_VOLUME_LOSS**

Purpose: To represent the effect of tunneling on surrounding structures, it is common to assume that a pre-defined fraction (e.g., 2%) of the volume occupied by the tunnel is lost during the construction process. This feature is available for solid elements only.

Part Set Cards. Include as many of these cards as desired. This input ends at the next keyword ("**") card.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|------|----|----|----|--------|--------|
| Variable | PSID | COORD | LCUR | FX | FY | FZ | PMIN | FACTOR |
| Type | I | I | I | F | F | F | F | F |
| Default | none | 0 | 0 | 1 | 1 | 1 | -1.e20 | .01 |

VARIABLE**DESCRIPTION**

| | |
|--------|---|
| PSID | Part Set ID |
| COORD | Coordinate System ID (default - global coordinate system) |
| LCUR | Curve ID containing volume fraction lost vs. time |
| FX | Fraction of strain occurring in x -direction |
| FY | Fraction of strain occurring in y -direction |
| FZ | Fraction of strain occurring in z -direction |
| PMIN | (Leave blank) |
| FACTOR | Feedback factor |

Remarks:

Volume loss is modeled by a process similar to thermal contraction: if the material is unrestrained it will shrink while remaining unstressed; if restrained, stresses will become more tensile. Typically the material surrounding the tunnel offers partial restraint; the volume loss algorithm adjusts the applied "thermal" strains to attempt to achieve the desired volume loss. Optionally, FX, FY and FZ may be defined: these will be treated as ratios for the x , y and z strains; this feature can be used to prevent contraction parallel to the tunnel axis.

The total volume of all the parts in the part set is monitored and output at the time-history interval (on *DATABASE_BINARY_D3THDT) to a file named `vloss_output`. This file contains lines of data (*time, volume1, volume2, volume3...*) where *volume1* is the total volume of elements controlled by the first *LOAD_VOLUME_LOSS card, *volume2* is the total volume of elements controlled by the second *LOAD_VOLUME_LOSS card, etc.

This feature works only with material types that use incremental strains to compute stresses. Thus, hyperelastic materials (e.g. MAT_027) are excluded, as are certain foam material types (e.g. MAT_083).

The feedback factor (see FACTOR field) controls how strongly the algorithm tries to impose the desired change of volumetric strain. The default value is recommended. If the volumetric response appears noisy or unstable, it may be necessary to reduce FACTOR. Alternatively, if the actual volumetric strain changes much more slowly than the input curve, it may be necessary to increase FACTOR.

*MODULE

The keyword *MODULE provides a way to load user compiled libraries at runtime, to support user defined capabilities such as material models, equations of state, element formulations, etc. The following keywords implement this capability:

*MODULE_LOAD

*MODULE_PATH

*MODULE_USE

*MODULE

*MODULE_LOAD

*MODULE_LOAD

Purpose: Load a dynamic library for user subroutines.

Card Sets. Repeat as many sets of data cards as desired (Cards 1 and 2) to load multiple libraries. This input ends at the next keyword (“*”) card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|-------|---|---|---|---|---|
| Variable | MDLID | | TITLE | | | | | |
| Type | A20 | | A60 | | | | | |
| Default | none | | none | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|---|---|---|---|---|---|---|
| Variable | FILENAME | | | | | | | |
| Type | A80 | | | | | | | |
| Default | none | | | | | | | |

VARIABLE

DESCRIPTION

MDLID Module identification. A unique string label must be specified.

TITLE Description of the module.

FILENAME File name of the library to be loaded, 80 characters maximum.
If the filename has no path component, LS-DYNA will search in all directories specified in *MODULE_PATH first. If not found and the filename starts with “+” (a plus sign), LS-DYNA will continue to search all directories specified in the system environment variable LD_LIBRARY_PATH.

Remarks:

1. **Library Restrictions.** The MODULE capability described here and in *MODULE_USE is still under development and is considered experimental. As such,

it is currently only supported in specially compiled executables on Linux systems.

2. **Execution Line Option.** If only one dynamic library is loaded and no rules are required (*MODULE_USE), this dynamic library can be specified through the execution line option "module=dll". The system environment variable LD_LIBRARY_PATH is also used for searching the dynamic library if the filename starts with "+". This execution line option provides the support to the classic user subroutine subroutines without modifying the input deck.

***MODULE_PATH_{OPTION}**

Available options:

<BLANK>

RELATIVE

LS-DYNA's default behavior is to search for modules in the current working directory. If a module file is not found and the filename has no path component, LS-DYNA will search in all directories specified on the cards following a *MODULE_PATH keyword. Multiple paths can be specified using one *MODULE_PATH keyword card, that is,

```
*MODULE_PATH  
Directory_path1  
Directory_path2  
Directory_path3
```

Directory paths are read until the next keyword ("*") card is encountered. A directory path can have up to 236 characters. See [Remark 3](#).

When the RELATIVE option is used, all directories are relative to the location of the input file. For example, if "i=/home/test/problems/input.k" is given on the command line, and the input contains

```
*MODULE_PATH_RELATIVE  
lib  
../lib
```

then the two directories /home/test/problems/lib and /home/test/lib will be searched for module files.

Remarks:

1. **Input Format.** Filenames and pathnames are limited to 236 characters spread over up to three 80 character lines. When 2 or 3 lines are needed to specify the filename or pathname, end the preceding line with "␣+" (space followed by a plus sign) to signal that a continuation line follows. Note that the "␣+" combination is, itself, part of the 80 character line; hence the maximum number of allowed characters is $78 + 78 + 80 = 236$.

***MODULE_USE**

Purpose: Define the rules for mapping the user subroutines loaded in dynamic libraries to the model. The rules can be applied to:

| | |
|-----------------------------------|--------------------|
| *MAT_USER_DEFINED_MATERIAL_MODELS | (MAT 41 - 50) |
| *MAT_THERMAL_USER_DEFINED | (MAT T11 - T15) |
| *EOS_USER_DEFINED | (EOS 21 - 30) |
| *SECTION_SOLID | (ELFORM 101 - 105) |
| *SECTION_SHELL | (ELFORM 101- 105) |

and other subroutines in the LS-DYNA user subroutine package.

LS-DYNA requires that subroutines in modules (see [*MODULE_LOAD](#)) be named as if they were part of the traditional user subroutine framework. Each module, however, can contain a complete set of those subroutines, and it is, therefore, possible to import in different modules the same subroutines of the same name several times. Each module is, essentially, an independent copy of the traditional user-subroutine framework. This keyword, `*MODULE_USE`, deals with namespace conflicts by defining how each subroutine in the module is presented to the other keywords.

The rules defined in `*MODULE_USE` are applied to only one dynamic library.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|---|---|---|---|---|---|
| Variable | MDLID | | | | | | | |
| Type | A20 | | | | | | | |
| Default | none | | | | | | | |

Rule Cards. Card 2 defines rules for the module specified in Card 1. Include one instance of this card for each subroutine to be mapped. If two rules conflict, new rules override existing rules. Input ends at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|--------|---|--------|---|---|---|
| Variable | TYPE | | PARAM1 | | PARAM2 | | | |
| Type | A20 | | A20 | | A20 | | | |
| Default | none | | blank | | blank | | | |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| MDLID | Module identification defined in *MODULE_LOAD. |
| TYPE | Rule type. See TYPE definitions below. |
| PARAM1 | Type dependent parameter. |
| PARAM2 | Type dependent parameter. |

User Defined Materials:**TYPE****DESCRIPTION**

UMAT Implements the user material type PARAM1 in the model via a possibly different type PARAM2 in the dynamic library. Types in the extended range from 1001 to 2000 can be used as material types in the model. For example, if PARAM1 = 1001 and PARAM2 = 42, then model material 1001 will use subroutine umat42 from this library.

If PARAM1 is blank and PARAM2 is not, then all user materials in the model will use the indicated subroutine from this library.

If PARAM2 is blank and PARAM1 is not, the material type PARAM1 in the model will use the traditional subroutine from this library. For example, if PARAM1 = 43 and PARAM2 is blank, then material type 43 in the model will use the subroutine umat43 from this library

If both PARAM1 and PARAM2 are blank, then all user defined

| TYPE | DESCRIPTION |
|-------------|---|
| | materials in the model will use the traditional subroutines from this library (41 → umat41, 42 → umat42, etc). |
| MATID | <p>Implements the user material having ID = PARAM1 via a possibly different material type PARAM2 in the dynamic library. PARAM2 may be blank if the material type defined in the model is the same as the one in the dynamic library.</p> <p>PARAM1 can be a numerical id or label of the material as defined in the model.</p> <p>Materials beyond user material models can be overloaded.</p> |

Thermal User Defined Materials:

| TYPE | DESCRIPTION |
|-------------|--|
| TUMAT | Implements the user thermal material type PARAM1 in the model (PARAM1 = 11-15) via type PARAM2 in the dynamic library. See type UMAT for the default rules. |
| TMATID | <p>Implements the user thermal material having ID = PARAM1 via thermal material type PARAM2 in the dynamic library. PARAM2 may be blank if the material type defined in the model is the same as the one in the dynamic library.</p> <p>PARAM1 can be a numerical id or label of the thermal material as defined in the model.</p> <p>Materials beyond user material models can be overloaded.</p> |

User Defined EOS:

| TYPE | DESCRIPTION |
|-------------|--|
| UEOS | Implements the user EOS model PARAM1 in the model (PARAM1 = 21-30) via EOS model PARAM2 in the dynamic library. See type UMAT for the default rules. |

User Defined Elements:

| TYPE | DESCRIPTION |
|-------------|--|
| UELEM | Implements the user element type PARAM1 in the model (PARAM1 = 101-105) via element type PARAM2 in the dynamic library. See type UMAT for the default rules. |

| TYPE | DESCRIPTION |
|-------------|---|
| SECTIONID | Implements the user element type with section ID = PARAM1 via element type PARAM2 in the dynamic library. PARAM2 may be blank if the element type defined in the model is the same as the one in the dynamic library. |

| |
|--|
| <p>Note: Solid element types are mapped to subroutine <code>usrslid</code>, and shell element types are mapped to subroutine <code>usrshl</code>. These interfaces are documented in <code>dyn21b.f</code>.</p> |
|--|

Other User Subroutines:

| TYPE | DESCRIPTION |
|--------------|---|
| | The following subroutines implemented in the dynamic library are used for the model. Any subroutines with the same name in other dynamic libraries, if they exist, are ignored. |
| UMATFAIL | matusr_24 matusr_103 |
| UFRICITION | usrfric |
| UWEAR | userwear |

| UOUTPUT | ushout |

Remarks:

1. In order to simplify the development of user defined materials via modules, the *MODULE_USE keyword can be omitted in one special case. If only a single module library will be used and no remapping of material types is desired, then a *MODULE_LOAD keyword may appear with a single library and no other *MODULE keywords. In this case, all the user defined subroutines found in this library will be used in the normal way. For example, if the library contains umat41 and umat43, those routines will be used for all materials of type 41 and 43 respectively, and the *MODULE_USE keyword describing this may be omitted.

*NODE

The keywords defined in this section include:

*NODE_{*OPTION*}

*NODE_MERGE_SET

*NODE_MERGE_TOLERANCE

*NODE_RIGID_SURFACE

*NODE_SCALAR_{*OPTION*}

*NODE_THICKNESS

*NODE_TO_TARGET_VECTOR

*NODE_TRANSFORM

***NODE_{OPTION}**

Available options include:

<BLANK>

MERGE

Purpose: Define a node and its coordinates in the global coordinate system. Also, the boundary conditions in global directions can be specified. Generally, nodes are assigned to elements; however, exceptions are possible (see [Remark 2](#) below). The nodal point ID must be unique relative to other nodes defined in the *NODE section.

The MERGE option is usually applied to boundary nodes on disjoint parts and only applies to nodes defined when the merge option is invoked. With this option, nodes with identical coordinates are replaced during the input phase by the first node encountered that shares the coordinate. During the merging process a tolerance is used to determine whether a node should be merged. This tolerance can be defined using the keyword *NODE_MERGE_TOLERANCE keyword, which is recommended over the default value. See the *NODE_MERGE_TOLERANCE input description in the next section.

Node Cards. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|------|----|----|----|----|----|---|---|---|----|
| Variable | NID | X | Y | Z | TC | RC | | | | |
| Type | I | F | F | F | I | I | | | | |
| Default | none | 0. | 0. | 0. | 0 | 0 | | | | |
| Remarks | | | | | | | | 1 | 1 | |

VARIABLE**DESCRIPTION**

| | |
|-----|--------------|
| NID | Node number |
| X | x coordinate |
| Y | y coordinate |
| Z | z coordinate |

| VARIABLE | DESCRIPTION |
|----------|---|
| TC | Translational Constraint: EQ.0: no constraints, EQ.1: constrained x displacement, EQ.2: constrained y displacement, EQ.3: constrained z displacement, EQ.4: constrained x and y displacements, EQ.5: constrained y and z displacements, EQ.6: constrained z and x displacements, EQ.7: constrained x , y , and z displacements. |
| RC | Rotational constraint: EQ.0: no constraints, EQ.1: constrained x rotation, EQ.2: constrained y rotation, EQ.3: constrained z rotation, EQ.4: constrained x and y rotations, EQ.5: constrained y and z rotations, EQ.6: constrained z and x rotations, EQ.7: constrained x , y , and z rotations. |

Remarks:

- 1. Boundary Conditions.** Boundary conditions can also be defined on nodal points in a local (or global) system by using the keyword `*BOUNDARY_SPC`. For other possibilities also see the `*CONSTRAINED` keyword section of the manual. No attempt should be made to apply boundary conditions to nodes belonging to rigid bodies (see `*MAT_RIGID` for application of rigid body constraints).
- 2. Massless Nodes.** A node without an element or a mass attached to it will be assigned a very small amount of mass and rotary inertia. Generally, massless nodes should not cause any problems but in rare cases may create stability problems if these massless nodes interact with the structure. Warning messages are printed when massless nodes are found. Also, massless nodes are used with rigid bodies to place joints, see `*CONSTRAINED_EXTRA_NODES_OPTION` and `*CONSTRAINED_NODAL_RIGID_BODY`.

***NODE_MERGE_SET**

Purpose: The MERGE_SET option is applied to a set of boundary nodes on disjoint part. With this option, nodes with identical coordinates that are members of any node set ID defined by this keyword are replaced during the input phase by one node within the set or sets. Of the nodes sharing the same coordinates, the node chosen is the one with the smallest ID. During the merging process a tolerance is used to determine whether a node should be merged. This tolerance can be defined using the keyword *NODE_MERGE_TOLERANCE keyword, which is recommended over the default value. See the *NODE_MERGE_TOLERANCE input description in the next section. Only nodes contained within the specified sets will be merged. Nodes contained within the set are defined by the *NODE keyword. With this option, the keyword *NODE_MERGE is not needed.

Node Set Cards. Include as many cards as desired. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | NSID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

VARIABLE**DESCRIPTION**

NSID

Node set ID containing list of nodes to be considered for merging.

*NODE_MERGE_TOLERANCE

Purpose: Define a tolerance that determines whether a node listed in *NODE_MERGE should be merged.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|---|---|---|---|---|---|
| Variable | TOLR | | | | | | | |
| Type | F | | | | | | | |
| Default | Rem 1 | | | | | | | |

VARIABLE

DESCRIPTION

| | |
|------|--|
| TOLR | Physical distance used to determine whether to merge a nodal pair of nearby nodes. |
|------|--|

Remarks:

- Default Tolerance.** If the tolerance, TOLR, is undefined or if it is defaulted to zero, a value is computed as:

$$TOLR = 10^{-5} \cdot \frac{XMAX + YMAX + ZMAX - XMIN - YMIN - ZMIN}{3 \times \sqrt[3]{NUMNP}}$$

where XMIN, XMAX, YMIN, YMAX, ZMIN, and ZMAX represent the minimum and maximum values of the (x, y, z) nodal point coordinates in the global coordinate system, and NUMNP is the number of nodal points.

*NODE

*NODE_RIGID_SURFACE

*NODE_RIGID_SURFACE

Purpose: Define a rigid node and its coordinates in the global coordinate system. These nodes are used to define rigid road surfaces, and they have no degrees of freedom. The nodal points are used in the definition of the segments that define the rigid surface. See *CONTACT_RIGID_SURFACE. The nodal point ID must be unique relative to other nodes defined in the *NODE section.

Node Cards. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|------|----|---|----|---|----|---|---|---|----|
| Variable | NID | X | | Y | | Z | | | | |
| Type | I | F | | F | | F | | | | |
| Default | none | 0. | | 0. | | 0. | | | | |

VARIABLE

DESCRIPTION

| | |
|-----|---------------------|
| NID | Node number |
| X | <i>x</i> coordinate |
| Y | <i>y</i> coordinate |
| Z | <i>z</i> coordinate |

***NODE_SCALAR_{OPTION}**

Available options include:

<BLANK>

VALUE

Purpose: Define a scalar nodal point which has a specified number of degrees-of-freedom. The scalar point ID must be unique relative to other nodes defined in the *NODE section.

Node Card. Card 1 for no keyword option (option set to <BLANK>). Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

| Card 1a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|------|------|---|---|---|---|---|---|---|----|
| Variable | NID | NDOF | | | | | | | | |
| Type | I | I | | | | | | | | |
| Default | none | 0 | | | | | | | | |

Node Card. Card 1 for the VALUE keyword option. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

| Card 1b | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
|----------|------|-----|-----|-----|------|---|---|
| Variable | NID | X1 | X2 | X3 | NDOF | | |
| Type | I | F | F | F | I | | |
| Default | none | 0.0 | 0.0 | 0.0 | 0 | | |

VARIABLE

DESCRIPTION

NID

Scalar node ID.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| NDOF | Number of degrees-of-freedom EQ.0: fully constrained EQ.1: one degree-of-freedom EQ.2: two degrees-of-freedom EQ.3: three degrees-of-freedom |
| X_i | Initial value of i^{th} degree of freedom. |

***NODE_THICKNESS_{OPTION1}_{OPTION2}**

For OPTION1 the available options include:

<BLANK>

SET

For OPTION2 the available options include:

<BLANK>

GENERATE

Purpose: Define nodal thickness that overrides nodal thickness otherwise determined via *SECTION_SHELL, *PART_COMPOSITE, or *ELEMENT_SHELL_THICKNESS. The option GENERATE generates a linear thickness distribution between a starting node (or node set) and a ending node (or node set).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|---|---|---|---|
| Variable | ID1 | THK | ID2 | INC | | | | |
| Type | I | F | I | I | | | | |
| Default | none | none | none | none | | | | |

VARIABLE**DESCRIPTION**

| | |
|-----|---|
| ID1 | Node ID, or node set ID if SET option is active. If GENERATE option is active, ID1 serves as the starting node (or node set). |
| THK | Thickness at node ID1, or node set ID1 if SET option is active (ignored if GENERATE option is active). |
| ID2 | Ending node (or node set) if GENERATE option is active. |
| INC | Increment in node numbers if GENERATE option is active. |

Remarks:

When the GENERATE option is active, both the starting and ending nodes (or node sets) must have a nodal thickness as defined by *NODE_THICKNESS or NODE_-

THICKNESS_SET. The sample commands shown below create a linear thickness distribution between node set 100 and node set 200.

```
*SET_NODE_LIST
100
1, 15, 39
*SET_NODE_LIST
200
7, 21, 45
*NODE_THICKNESS_SET
$ assign thickness of 2.0 to node 1, 15 and 39
100, 2.0
*NODE_THICKNESS_SET
$ assign thickness of 5.0 to node 7, 21 and 45
200, 5.0
*NODE_THICKNESS_SET_GENERATE
$ assign thickness of 3. (= 2.+1.) to node 3 (=1+2), 17 (=15+2) and 41 (=39+2)
$ assign thickness of 4. (= 2.+2.) to node 5 (=1+4), 19 (=15+4) and 43 (=39+4)
100,, 200, 2
```

***NODE_TO_TARGET_VECTOR**

Purpose: When the input contains a *CONTROL_FORMING_BESTFIT_VECTOR card, LS-DYNA writes as output a keyword file named **bestfit.out**. Unlike most keyword cards, which are read by LS-DYNA to define a model, LS-DYNA's keyword reader ignores this card. This card and its associated data cards are a kind of output for the user's benefit (or for post-processing).

Recall that the *CONTROL_FORMING_BESTFIT_VECTOR keyword (mentioned above) rigidly moves a part to best fit a target, such as a scanned part. For each node of the best fit part LS-DYNA writes a data card (Card 1, below) consisting of the components of the vector that is the shortest distance from the node to the target.

Node Cards. As many cards as needed are output in the following format. This output ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|------|--------|---|--------|---|--------|---|---|---|----|
| Variable | NID | XDELTA | | YDELTA | | ZDELTA | | | | |
| Type | I | F | | F | | F | | | | |
| Default | none | 0. | | 0. | | 0. | | | | |

VARIABLE**DESCRIPTION**

| | |
|--------|---|
| NID | Node ID on a part best fitted to the target. |
| XDELTA | <i>x</i> -component of the shortest vector from the node to the target |
| YDELTA | <i>y</i> -component of the shortest vector from the node to the target. |
| ZDELTA | <i>z</i> -component of the shortest vector from the node to the target. |

Revision Information:

The keyword is available starting from revision 112655.

*NODE

*NODE_TRANSFORM

*NODE_TRANSFORM

Purpose: Perform a transformation on a node set based on a transformation defined by the keyword *DEFINE_TRANSFORMATION.

Transformation Cards. Include as many cards in the following format as desired. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|------|---|---|---|---|---|---|
| Variable | TRSID | NSID | | | | | | |
| Type | I | I | | | | | | |
| Default | none | none | | | | | | |

VARIABLE

DESCRIPTION

| | |
|-------|--|
| TRSID | The ID of the transformation defined under *DEFINE_TRANSFORMATION. |
| NSID | Node set ID of the set of nodes to be subject to the transformation. |

*PARAMETER

The *PARAMETER family of commands assign numerical values or expressions to named parameters. The parameter names can be used subsequently in the input in place of numerical values.

*PARAMETER_OPTION

*PARAMETER_DUPLICATION

*PARAMETER_EXPRESSION

*PARAMETER_TYPE

***PARAMETER_{OPTION}_{OPTION}**

The available options are

<BLANK>

LOCAL

MUTABLE

Purpose: Define the numerical values of parameter names referenced throughout the input file. The parameter definitions, if used, should be placed at the beginning of the input file following *KEYWORD or at the beginning of an include file if the LOCAL option is specified.

Parameter Cards. Include as many cards as necessary.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-----------|-------|-----------|-------|-----------|-------|-----------|
| Variable | PRMR1 | VAL1 | PRMR2 | VAL2 | PRMR3 | VAL3 | PRMR4 | VAL4 |
| Type | A | I, F or C |
| Default | none | none | none | none | none | none | none | none |

VARIABLE

DESCRIPTION

PRMR n

PRMR n sets both the n^{th} parameter and its storage type.

PRMR = T xxxxxxxxxx
9 character name

The first character, "T", is decoded as follows:

T.EQ."R": Parameter is a real number

T.EQ."I": Parameter is an integer

T.EQ."C": Parameter is a character

The remaining 9 characters specify the name of the parameter. A parameter name "time" (case insensitive) is disallowed.

For example, to define a shell thickness named, "SHLTHK", the input "RSHLTHK", "R SHLTHK", or "R SHLTHK " are all equivalent 10 character strings (" " is space). For instructions regarding how to use the variable "SHLTHK," see [Remark 1](#).

| VARIABLE | DESCRIPTION |
|----------|---|
| VAL n | Define the value of the n^{th} parameter as either a real or integer number, or a character string consistent with preceding definition for PRMR n . |

Remarks:

1. **Syntax for Using Parameters.** Parameters can be referenced anywhere in the input by placing an "&" immediately preceding the parameter name. If a minus sign "-" is placed directly before "&", i.e., "-&", with no space the sign of the numerical value will be switched.
2. **LOCAL Option.** *PARAMETER_LOCAL behaves like the *PARAMETER keyword with one difference. A parameter defined by *PARAMETER without the LOCAL option is visible and available at any later point in the input processing. Parameters defined with the LOCAL versions disappear when the input parser finishes reading the file in which they appear. LOCAL variables can temporarily mask non-LOCAL variables.

For example, suppose you have the following input files:

main.k:

```
*PARAMETER
R VAL1 1.0
*PARAMETER
R VAL2 2.0
*PARAMETER
R VAL3 3.0
*CONTROL_TERMINATION
  &VAL1
*INCLUDE
file1
```

file1:

```
*PARAMETER
R VAL1 10.0
*PARAMETER_LOCAL
R VAL2 20.0
*PARAMETER_LOCAL
R VAL4 40.0
*INCLUDE
file2
:
```

Then, inside file2 we will see VAL1 = 10.0, VAL2 = 20.0, VAL3 = 3.0 and VAL4 = 40.0. In main.k, after returning from file1, we will see VAL1 = 10.0, VAL2 = 2.0, and VAL3 = 3.0. VAL4 will not exist. This allows for include files that can set all their own parameters without clobbering the parameters in the rest of the input.

3. **MUTABLE Option for Redefining.** The MUTABLE option is used to indicate that an integer or real parameter may be redefined at some later point in the input processing (it is ignored for character parameters). Redefinition is allowed regardless of the setting of *PARAMETER_DUPLICATION. The MUTABLE qualifier must appear on the first definition of the parameter. It is not required on any later redefinition.

***PARAMETER_DUPLICATION**

Purpose: The purpose is to control how the code behaves if a duplicate parameter definition is found in the input.

| | | | | | | | | |
|----------|-------|---|---|---|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | DFLAG | | | | | | | |
| Type | I | | | | | | | |
| Default | 1 | | | | | | | |

VARIABLE

DESCRIPTION

DFLAG

Flag to control treatment of duplicate parameter definitions:

EQ.1: issue a warning and ignore the new definition (default)

EQ.2: issue a warning and accept the new definition

EQ.3: issue an error and ignore (terminates at end of input)

EQ.4: accept silently

EQ.5: ignore silently

Remarks:

- LOCAL and non-LOCAL Variables.** A LOCAL variable appearing in a file, which masks a non-LOCAL parameter, won't trigger these actions; however, a LOCAL that masks another LOCAL or a non-LOCAL that masks a non-LOCAL will.
- Multiple Cards.** Only one *PARAMETER_DUPLICATION card is allowed. If more than one is found, a warning is issued and any after the first are ignored.

***PARAMETER_EXPRESSION_{OPTION}**

The available options are

<BLANK>

LOCAL

MUTABLE

Purpose: Define the numerical values of parameter names referenced throughout the input file. Like the *PARAMETER keyword, but allows for general algebraic expressions, not simply fixed values. The LOCAL option allows for include files to contain their own unique expressions without clobbering the expressions in the rest of the input. See the *PARAMETER keyword.

Parameter Cards. Include as many cards as necessary.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------------|---|---|---|---|---|---|
| Variable | PRMR1 | EXPRESSION1 | | | | | | |
| Type | A | A | | | | | | |
| Default | none | none | | | | | | |

VARIABLE**DESCRIPTION**

PRMR n

Define the n th parameter in a field of 10. Within this field the first character must be either an "R" for a real number, "I" for an integer, or "C" for a character string. Lower or upper case for "I/C/R" is okay. Following the type designation, define the name of the parameter using up to, but not exceeding nine characters. For example, when defining a shell thickness named, "SHLTHK", both inputs "RSHLTHK" or "R SHLTHK" can be used and placed anywhere in the field of 10. When referencing SHLTHK in the input file, see [Remark 1](#) below.

EXPRESSION n

General expression which is evaluated, having the result stored in PRMR n . The following functions are available:

sin, cos, tan, csc, sec, ctn, asin, acos, atan, atan2, sinh, cosh, tanh, asinh, acosh, atanh, min, max, sqrt, mod, abs, sign, int, aint, nint, anint, float, exp, log, log10, float, pi, and general arithmetic expressions involving +, -, *, /, and **.

| VARIABLE | DESCRIPTION |
|----------|-------------|
|----------|-------------|

The standard rules regarding operator precedence are obeyed, and nested parentheses are allowed. The expression can reference previously defined parameters (with or without the leading &). The expression can be continued on multiple lines simply by leaving the first 10 characters of the continuation line blank.

For type "C" parameters, the expression is not evaluated in any sense, just stored as a string.

Remarks:

1. **Referencing Parameters.** Parameters can be referenced anywhere in the input by placing an "&" immediately preceding the parameter name. Expressions can be included in the input when placed between brackets "<>" as long as the total line length does not exceed 80 columns and fields are comma-delimited. For example, this...

```
*parameter
rterm, 0.2, istates, 80
*parameter_expression
rplot, term/(states-30)
*DATABASE_BINARY_D3PLOT
&plot
```

is equivalent to

```
*parameter
rterm, 0.2, istates, 80
*DATABASE_BINARY_D3PLOT
<term/(states-30)> ,
```

2. **Expression Properties.** Properties used when evaluating the expressions are listed below.
 - a) The integer and real properties of constants and parameters are honored when evaluating expressions. So 2/5 becomes 0, but 2.0/5 becomes 0.4.
 - b) The sign, atan2, min, max, and mod functions all take two arguments. The others all take only 1.
 - c) Functions that use an angle as their argument, e.g., sin or cos, assume the angle is in radians.

- d) The unary minus has higher precedence than exponentiation, that is, the formula $-3**2$ will be interpreted as $(-3)^2 = 9$.
3. **Redefining Parameters.** The MUTABLE option is used to indicate that an integer or real parameter may be redefined at some later point in the input processing (it is ignored for character parameters). Redefinition is allowed regardless of the setting of *PARAMETER_DUPLICATION. The MUTABLE qualifier must appear on the first definition of the parameter. It is not required on any later redefinition.

***PARAMETER_TYPE**

*PARAMETER_TYPE is a variation on the *PARAMETER keyword command. In addition to its basic function of associating a parameter name (PRMR) with a numerical value (VAL), the *PARAMETER_TYPE command also includes information (PRTYP) about how the parameter is used by LS-DYNA, such as a Part ID or as a segment set ID.

*PARAMETER_TYPE is useful only when (1) the parameter is used to represent an integer ID number, and (2) LS-PrePost is used to combine two or more models (keyword decks) into a larger model.

Only by knowing how the parameter is used by LS-DYNA is LS-PrePost able to increment the parameter value by the proper “offset” when LS-PrePost combines two or more input decks together into a larger deck. These offsets are necessary so that IDs of a certain type, such as Part IDs, are not duplicated in the assembled model. Figure 31-1 (b) shows the offset input dialog box of LS-PrePost where offset values for specific ID types are assigned.

Background:

This command is designed to support workflows involving models that are built up from discrete subassemblies created by independent workgroups. As the subassembly models evolve through the design process, Part IDs, material IDs, etc. in the models may change with each design iteration; therefore, it is advantageous to parameterize those IDs. In this way, though the parameter values may change, the parameter names remain the same. When the subassembly models are combined by LS-PrePost to create a larger model of an assembly or of a complete system, for instance, an aircraft engine model, parameter values assigned using *PARAMETER_TYPE are incremented by the proper ID offset value as prescribed when LS-PrePost imports each keyword file.

Card Format:

Parameter Cards. For each parameter with type information, include an additional card. This input ends at the next keyword (“*”) card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-------|---|---|---|---|---|
| Variable | PRMR | VAL | PRTYP | | | | | |
| Type | A | I | A | | | | | |
| Default | none | none | none | | | | | |

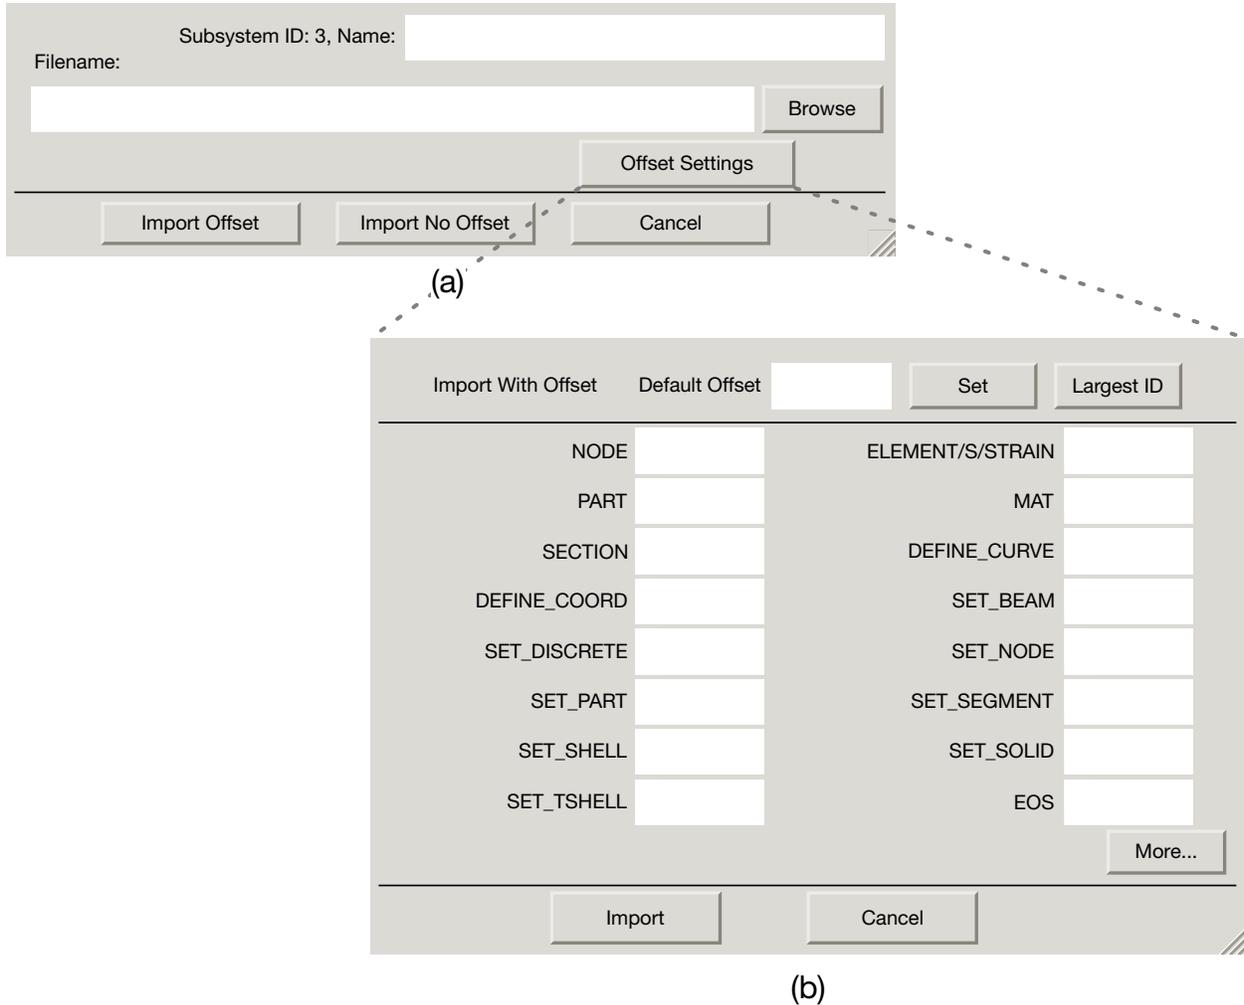

Figure 31-1. (a) the *file* → *import* → *keyword dialog box*; (b) the LS-PrePost dialog that takes the offset as a function of ID type.

VARIABLE

DESCRIPTION

PRMR

PRMR must be in the following format

$$\text{PRMR} = \text{I} \underline{\text{xxxxxxxxxx}}$$

9 character name

The first character is the type indicator and must be set to “I” for integer. The remaining 9 characters specify the name of the parameter.

For example, to define a part ID “WHLPID”, the input “IWHLPID”, “IWHLPID”, or “IWHLPID” are all equivalent 10 character strings (“” is space). For instructions regarding how to use the variable “WHLPID” see [Remark 1](#).

| VARIABLE | DESCRIPTION |
|----------|---|
| VAL | Define the value of the parameter. The VAL field must contain an integer. |
| PRTYP | <p>Describes, for the benefit of LS-PrePost only, how the parameter PRMR is used by LS-DYNA. PRTYP is ignored by LS-DYNA. For example, if VAL represents a Part ID, then PRTYP should be set to "PID". Knowing how the parameter is used by LS-DYNA, LS-PrePost can apply the appropriate offset to VAL when input decks are combined using LS-PrePost.</p> <p>EQ.NID: Node ID, EQ.NSID: Node set ID, EQ.PID: Part ID, EQ.PSID: Part set ID, EQ.MID: Material ID, EQ.EOSID: Equation of state ID, EQ.BEAMID: Beam element ID, EQ.BEAMSID: Beam element set ID, EQ.SHELLID: Shell element ID, EQ.SHELLSID: Shell element set ID, EQ.SOLIDID: Solid element ID, EQ.SOLIDSID: Solid element set ID, EQ.TSHELLID: Tshell element ID, EQ.TSHELLSID: Tshell element set ID, EQ.SSID: Segment set ID</p> |

Remarks:

- Referencing Parameters.** Parameters can be referenced anywhere in the input by placing an "&" at the first column of its field followed by the name of the parameter without blanks. For example, if PRMR is set to "I_□WHLPID_□", then the appropriate reference is "&WHLPID".

Example:

```
*PARAMETER_TYPE
I WHLPID 100 PID
I WHLMID 300 MID
```

*PART
Wheel
&WHLPID, 200, &WHLMID

2. **LS-PrePost.** *PARAMETER_TYPE is only supported by LS-PrePost 4.1 or later.
3. **Use Limitations.** Combining *INCLUDE_TRANSFORM with *PARAMETER_TYPE is unsupported. This will introduce conflicting parameter offset values, and offset values specified in *INCLUDE_TRANSFORM will override offset values associated with *PARAMETER_TYPE.

*PART

The following keywords are used in this section:

*PART_{*OPTION1*}_{*OPTION2*}_{*OPTION3*}_{*OPTION4*}_{*OPTION5*}

*PART_ADAPTIVE_FAILURE

*PART_ANNEAL

*PART_COMPOSITE_{*OPTION*}

*PART_DUPLICATE

*PART_MODES

*PART_MOVE

*PART_SENSOR

*PART_STACKED_ELEMENTS

***PART_{OPTION1}_{OPTION2}_{OPTION3}_{OPTION4}_{OPTION5}**

For *OPTION1* the available options are

<BLANK>

INERTIA

REPOSITION

For *OPTION2* the available options are

<BLANK>

CONTACT

For *OPTION3* the available options are

<BLANK>

PRINT

For *OPTION4* the available options are

<BLANK>

ATTACHMENT_NODES

For *OPTION5* the available options are

<BLANK>

AVERAGED

Options 1, 2, 3, 4, and 5 may be specified in any order on the *PART card.

Purpose: Define parts, that is, combine material information, section properties, hourglass type, thermal properties, and a flag for part adaptivity.

The INERTIA option allows the inertial properties and initial conditions to be defined rather than calculated from the finite element mesh. This applies to rigid bodies, see *MAT_RIGID, only.

The REPOSITION option applies to deformable materials and is used to reposition deformable materials attached to rigid dummy components whose motion is controlled by either CAL3D or MADYMO. At the beginning of the calculation each component controlled by CAL3D/MADYMO is automatically repositioned to be consistent with

the CAL3D/MADYMO input. However, deformable materials attached to these components will not be repositioned unless this option is used.

The CONTACT option allows part based contact parameters to be used with the automatic contact types a3, 4, a5, b5, a10, 13, a13, 15 and 26, that is

- *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE,
- *CONTACT_AUTOMATIC_SURFACE_TO_SURFACE_MORTAR,
- *CONTACT_SINGLE_SURFACE,
- *CONTACT_AUTOMATIC_NODES_TO_SURFACE,
- *CONTACT_AUTOMATIC_BEAMS_TO_SURFACE,
- *CONTACT_AUTOMATIC_ONE_WAY_SURFACE_TO_SURFACE,
- *CONTACT_AUTOMATIC_SINGLE_SURFACE,
- *CONTACT_AUTOMATIC_SINGLE_SURFACE_MORTAR,
- *CONTACT_AIRBAG_SINGLE_SURFACE,
- *CONTACT_ERODING_SINGLE_SURFACE,
- *CONTACT_AUTOMATIC_GENERAL.

The default values to use for these contact parameters can be specified on the *CONTACT input section card.

The PRINT option allows user control over whether output data is written into the ASCII files matsum and rbdout. See *DATABASE_ASCII.

The AVERAGED option may be applied *only* to parts consisting of a single (non-branching) line of truss elements. The average strain and strain rate over the length of the truss elements in the *part* is calculated, and the resulting average axial force is applied to all the elements in the part. Truss elements in an averaged part form one long continuous “macro-element.” The time step size for an AVERAGED part is based on the total length of the assembled trusses, rather than on the shortest truss.

Effectively, the truss elements of an AVERAGED part behave as a string under uniform tension. In an AVERAGED part there are no internal forces acting to keep the nodes separated, and other force contributions from the surrounding system *must* play that role. Therefore, the nodes connected to the truss elements should be attached to other structural members. This model is prototypically used for modeling cables in

mechanical actuators. The AVERAGED option can be activated for all material types, which are available for truss elements.

Card Summary:

Card Sets. Repeat as many sets of data cards as desired (Card 1 through 10 depending on options). This input ends at the next keyword (“*”) card.

Card 1. This card is required.

| | |
|---------|--|
| HEADING | |
|---------|--|

Card 2. This card is required.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | HEADING | | | | | | | |
| Type | C | | | | | | | |
| Default | none | | | | | | | |

| <u>VARIABLE</u> | <u>DESCRIPTION</u> |
|-----------------|----------------------|
| HEADING | Heading for the part |

| | | | | | | | | |
|----------|------|----------|----------|----------|----------|------|--------|----------|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | PID | SECID | MID | EOSID | HGID | GRAV | ADPOPT | TMID |
| Type | I/A | I or A10 | I or A10 | I or A10 | I or A10 | I | I | I or A10 |
| Default | none | none | none | 0 | 0 | 0 | 0 | 0 |

| <u>VARIABLE</u> | <u>DESCRIPTION</u> |
|-----------------|--|
| PID | Part identification. A unique number or label must be specified. |
| SECID | Section identification defined in a *SECTION keyword. See Remark 7 . |
| MID | Material identification defined in the *MAT section. See Remark 7 . |
| EOSID | Equation of state identification defined in the *EOS section. Nonzero only for solid elements using an equation of state to compute pressure. See Remark 7 . |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| HGID | <p>Hourglass/bulk viscosity identification defined in the *HOURLASS Section. See Remark 7.</p> <p>EQ.0: default values are used.</p> |
| GRAV | <p>Flag to turn on gravity initialization according to *LOAD_DENSITY_DEPTH.</p> <p>EQ.0: Part will be initialized only if included in the part set PSID in *LOAD_DENSITY_DEPTH.</p> <p>EQ.1: Part will be initialized irrespective of PSID in *LOAD_DENSITY_DEPTH.</p> |
| ADPOPT | <p>Indicate if this part is adapted or not. (See also *CONTROL_ADAPTIVE):</p> <p>LT.0: <i>r</i>-adaptive remeshing for 2D solids, ADOPT gives the load curve ID that defines the element size as a function of time.</p> <p>EQ.0: Adaptive remeshing is inactive for this part ID.</p> <p>EQ.1: <i>h</i>-adaptive for 3D shells.</p> <p>EQ.2: <i>r</i>-adaptive remeshing for 2D solids, 3D tetrahedrons and 3D EFG.</p> <p>EQ.3: Axisymmetric <i>r</i>-adaptive remeshing for 3D solid (see Remark 6).</p> <p>EQ.9: Passive <i>h</i>-adaptive for 3D shells. The elements in this part will not be split unless their neighboring elements in other parts need to be split more than one level.</p> |
| TMID | <p>Thermal material property identification defined in the *MAT_THERMAL Section. Thermal properties must be specified for all solid, shell, and thick shell parts if a thermal or coupled thermal structural/analysis is being performed. Discrete elements are not considered in thermal analyses. See Remark 7.</p> |

Inertia Card 1. Additional Card for the INERTIA option. See [Remarks 2, 3, and 4](#).

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|----|----|------|--------|---|---|
| Variable | XC | YC | ZC | TM | IRCS | NODEID | | |
| Type | F | F | F | F | I | I | | |

VARIABLE**DESCRIPTION**

| | |
|--------|---|
| XC | Global x -coordinate of center of mass. If nodal point, NODEID, is defined XC, YC, and ZC are ignored and the coordinates of the nodal point, NODEID, are taken as the center of mass. |
| YC | Global y -coordinate of center of mass |
| ZC | Global z -coordinate of center of mass |
| TM | Translational mass |
| IRCS | Flag for inertia tensor reference coordinate system: EQ.0: global inertia tensor, EQ.1: local inertia tensor is given in a system defined by the orientation vectors. |
| NODEID | Nodal point defining the CG of the rigid body. This node should be included as an extra node for the rigid body; however, this is not a requirement. If this node is free, its motion will not be updated to correspond with the rigid body after the calculation begins. |

Inertia Card 2. Additional Card for the INERTIA option.

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-----|-----|---|---|
| Variable | IXX | IXY | IXZ | IYY | IYZ | IZZ | | |
| Type | F | F | F | F | F | F | | |

VARIABLE**DESCRIPTION**

| | |
|-----|---|
| IXX | I_{xx} , xx component of inertia tensor (see Remark 4) |
|-----|---|

| VARIABLE | DESCRIPTION |
|-----------------|---|
| IXY | I_{xy} , xy component of inertia tensor (see Remark 4) |
| IXZ | I_{xz} , xz component of inertia tensor (see Remark 4) |
| IYY | I_{yy} , yy component of inertia tensor (see Remark 4) |
| IYZ | I_{yz} , yz component of inertia tensor (see Remark 4) |
| IZZ | I_{zz} , zz component of inertia tensor (see Remark 4) |

Inertia Card 3. Additional Card for the INERTIA option.

| Card 5 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-----|-----|---|---|
| Variable | VTX | VTY | VTZ | VRX | VRX | VRZ | | |
| Type | F | F | F | F | F | F | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| VTX | initial translational velocity of rigid body in global x -direction (see Remark 5) |
| VTY | initial translational velocity of rigid body in global y -direction (see Remark 5) |
| VTZ | initial translational velocity of rigid body in global z -direction (see Remark 5) |
| VRX | initial rotational velocity of rigid body about global x -axis (see Remark 5) |
| VRX | initial rotational velocity of rigid body about global y -axis (see Remark 5) |
| VRZ | initial rotational velocity of rigid body about global z -axis (see Remark 5) |

Inertial Coordinate System Card. Optional card required for IRCS = 1 with INERTIA option. Define two local vectors or a local coordinate system ID.

| Card 6 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|----|------|------|------|-----|---|
| Variable | XL | YL | ZL | XLIP | YLIP | ZLIP | CID | |
| Type | F | F | F | F | F | F | I | |
| Remark | 1 | 1 | 1 | 1 | 1 | 1 | | |

VARIABLE**DESCRIPTION**

| | |
|------|--|
| XL | <i>x</i> -coordinate of local <i>x</i> -axis. Origin lies at (0,0,0). |
| YL | <i>y</i> -coordinate of local <i>x</i> -axis |
| ZL | <i>z</i> -coordinate of local <i>x</i> -axis |
| XLIP | <i>x</i> -coordinate of vector in local <i>x-y</i> plane |
| YLIP | <i>y</i> -coordinate of vector in local <i>x-y</i> plane |
| ZLIP | <i>z</i> -coordinate of vector in local <i>x-y</i> plane |
| CID | Local coordinate system ID, see *DEFINE_COORDINATE_... With this option leave fields 1 - 6 blank. |

Reposition Card. An additional Card is for the REPOSITION option.

| Card 7 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|--------|---|---|---|---|---|
| Variable | CMSN | MDEP | MOVOPT | | | | | |
| Type | I | I | I | | | | | |

VARIABLE**DESCRIPTION**

| | |
|------|--|
| CMSN | CAL3D segment number / MADYMO system number. See the numbering in the corresponding program. |
|------|--|

| VARIABLE | DESCRIPTION |
|-----------------|--|
| MDEP | MADYMO ellipse/plane number: GT.0: ellipse number, EQ.0: default, LT.0: absolute value is plane number. |
| MOVOPT | Flag to deactivate moving for merged rigid bodies, see *CONSTRAINED_RIGID_BODIES. This option allows a merged rigid body to be fixed in space while the nodes and elements of the generated CAL3D / MADYMO parts are repositioned: EQ.0: merged rigid body is repositioned, EQ.1: merged rigid body is not repositioned. |

Contact Card. Additional Card is required for the CONTACT option.

| Card 8 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|----|----|------|-----|-----|--------|
| Variable | FS | FD | DC | VC | OPTT | SFT | SSF | CPARM8 |
| Type | F | F | F | F | F | F | F | F |

NOTE: If FS, FD, DC, and VC are specified they will not be used unless FS is set to a negative value (-1.0) in the *CONTACT section. These frictional coefficients apply only to contact types:

SINGLE_SURFACE,
 AUTOMATIC_GENERAL,
 AUTOMATIC_SINGLE_SURFACE,
 AUTOMATIC_SINGLE_SURFACE_MORTAR,
 AUTOMATIC_NODES_TO_....,
 AUTOMATIC_SURFACE_....,
 AUTOMATIC_SURFACE_..._MORTAR,
 AUTOMATIC_ONE_WAY_....,
 ERODING_SINGLE_SURFACE

Default values are input via *CONTROL_CONTACT input.

| VARIABLE | DESCRIPTION |
|----------|--|
| FS | <p>Static coefficient of friction. The functional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact,</p> $\mu_c = FD + (FS - FD)e^{-DC \times v_{rel} }.$ <p>For mortar contact $\mu_c = FS$, that is, dynamic effects are ignored.</p> |
| FD | <p>Dynamic coefficient of friction. The functional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact</p> $\mu_c = FD + (FS - FD)e^{-DC \times v_{rel} }.$ <p>For mortar contact $\mu_c = FS$, that is, dynamic effects are ignored.</p> |
| DC | <p>Exponential decay coefficient. The functional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact</p> $\mu_c = FD + (FS - FD)e^{-DC \times v_{rel} }.$ <p>For mortar contact $\mu_c = FS$ (dynamical effects are ignored).</p> |
| VC | <p>Coefficient for viscous friction. This is necessary to limit the friction force to a maximum. A limiting force is computed by</p> $F_{lim} = VC \times A_{cont},$ <p>where A_{cont} is the area of the segment contacted by the node in contact. The suggested value for VC is to use the yield stress in shear $VC = \sigma_0 / \sqrt{3}$ where σ_0 is the yield stress of the contacted material.</p> |
| OPTT | <p>Optional contact thickness. This applies to solids, shells and beams.</p> |
| SFT | <p>Optional thickness scale factor for PART ID in automatic contact (scales true thickness). This option applies only to contact with shell elements. True thickness is the element thickness of the shell elements.</p> |
| SSF | <p>Scale factor on default slave penalty stiffness for this PART ID whenever it appears in the contact definition. If zero, SSF is taken as unity.</p> |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| CPARM8 | <p>Flag to exclude beam-to-beam contact from the same PID for CONTACT_AUTOMATIC_GENERAL. This applies only to MPP. Global default may be set using CPARM8 on *CONTACT_..._MPP Optional Card.</p> <p>EQ.0: Flag is not set (default).</p> <p>EQ.1: Flag is set.</p> <p>EQ.2: Flag is set. CPARM8 = 2 has the additional effect of permitting contact treatment of spot weld (type 9) beams in AUTOMATIC_GENERAL contacts; spot weld beams are otherwise disregarded entirely by AUTOMATIC_GENERAL contacts.</p> |

Print Card. An additional card is required for the PRINT option. This option applies to rigid bodies and provides a way to turn off ASCII output in files rbdout and matsum.

| Card 9 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | PRBF | | | | | | | |
| Type | I | | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| PRBF | <p>Print flag for rbdout and matsum files.</p> <p>EQ.0: default is taken from the keyword *CONTROL_OUTPUT.</p> <p>EQ.1: write data into rbdout file only</p> <p>EQ.2: write data into matsum file only</p> <p>EQ.3: do not write data into rbdout and matsum</p> |

Attachment Nodes Card. Additional card required for the ATTACHMENT_NODES option. See [Remark 8](#).

| Card 10 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|---|---|---|---|---|---|
| Variable | ANSID | | | | | | | |
| Type | I | | | | | | | |

VARIABLE**DESCRIPTION**

ANSID

Attachment node set ID. See [Remark 8](#). This option should be used very cautiously and applies only to rigid bodies. The attachment point nodes are updated each cycle whereas other nodes in the rigid body are updated only in the output databases. All loads seen by the rigid body must be applied through this nodal subset or directly to the center of gravity of the rigid body. If the rigid body is in contact, this set must include all interacting nodes.

EQ.0: All nodal updates are skipped for this rigid body. The null option can be used if the rigid body is fixed in space or if the rigid body does not interact with other parts, for example, the rigid body is only used for some visual purpose.

Remarks:

1. **Local Inertia Tensor Coordinate System.** The local Cartesian coordinate system is defined as described in *DEFINE_COORDINATE_VECTOR. The local z-axis vector is the vector cross product of the x-axis and the in-plane vector. The local y-axis vector is finally computed as the vector cross product of the z-axis vector and the x-axis vector. The local coordinate system defined by CID has the advantage that the local system can be defined by nodes in the rigid body which makes repositioning of the rigid body in a pre-processor much easier since the local system moves with the nodal points.
2. **Inertia Option and Shared Rigid/Deformable Nodes.** When specifying mass properties for a rigid body using the inertia option, the mass contributions of deformable bodies to nodes which are shared by the rigid body should be considered as part of the rigid body.
3. **Inertia Option Lacks Default Values.** If the inertia option is used, all mass and inertia properties of the body *must* be specified. *There are no default values.*

4. **Inertia Tensor Characteristics.** The inertia terms are always with respect to the center of mass of the rigid body. The reference coordinate system defines the orientation of the axes, not the origin. Note that the off-diagonal terms of the inertia tensor are opposite in sign from the products of inertia.
5. **Initial Velocity Card for Rigid Bodies.** The initial velocity of the rigid body may be overwritten by the *INITIAL_VELOCITY card.
6. **Axisymmetric Remeshing.** Axisymmetric remeshing is specially for 3D orbital forming. The adaptive part using this option needs to meet the following requirements for both geometry and discretization:
 - a) The geometry is (quasi-) symmetric with respect to the local z-axis, which in turn must be parallel to the global z-axis. See CID in *CONTROL_REMESHING.
 - b) A set of 2D cross-sections with uniform angular interval around z-axis are discretized by mixed triangular and quadrilateral elements in a similar pattern.
 - c) A set of circular lines around the z-axis pass through the nodes of the cross-sections and form orbital pentahedrons and hexahedrons.
7. **Allowed ID Values.** The variables SID, MID, EOSID, HGID, and TMID in *PART, and in *SECTION, *MAT, *EOS, *HOURGLASS, and *MAT_THERMAL, respectively, may be input as an 10-character alphanumeric variable (20-characters if long format is used), for example, "HS Steel", or as an integer not to exceed $2^{32} - 1$, e.g., "123456789" is allowed.
8. **Attachment Nodes Option.** All nodes are treated as attachment nodes if this option is not used. Attachment nodes apply to rigid bodies only. The motion of these nodes, which must belong to the rigid body, are updated each cycle. Other nodes in the rigid body are updated only for output purposes. Include all nodes in the attachment node set which interact with the structure through joints, contact, merged nodes, applied nodal point loads, and applied pressure. Include all nodes in the attachment node set if their displacements, accelerations, and velocities are to be written into an ASCII output file. Body force loads are applied to the center of gravity of the rigid body.

***PART_ADAPTIVE_FAILURE**

Purpose: This is an option for two-dimensional adaptivity to allow a part that is singly connected to split into two parts. This option is under development and will be generalized in the future to allow the splitting of parts that are multiply connected.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|---|---|---|---|---|---|---|
| Variable | PID | T | | | | | | |
| Type | I | F | | | | | | |

VARIABLE

DESCRIPTION

PID

Part ID

T

Thickness. When the thickness of the part reaches this minimum value the part is split into two parts. *The value for T should be on the order of the element thickness of a typical element.*

***PART_ANNEAL**

Available options include:

<BLANK>

SET

Purpose: To initialize the stress states at integration points within a specified part to zero at a given time during the calculation. This option is valid for parts that use constitutive models where the stress is incrementally updated. This option applies to the Hughes-Liu beam elements, the integrated shell elements, thick shell elements, and solid elements. In addition to the stress tensor components, the effective plastic strain is also set to zero.

Part Cards. Include as many parts cards as desired. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|------|---|---|---|---|---|---|
| Variable | PID/PSID | TIME | | | | | | |
| Type | I | F | | | | | | |
| Default | none | none | | | | | | |

VARIABLE

DESCRIPTION

PID/PSID

Part ID or part set ID if the SET option is active.

TIME

Time when the stress states are reinitialized.

***PART_COMPOSITE_{OPTION}**

Available options include:

<BLANK>

CONTACT

TSHELL

LONG

Purpose: The following input provides a simplified method of defining a composite material model for shell elements and thick shell (TSHELL) elements that eliminates the need for user defined integration rules and part ID's for each composite layer. When *PART_COMPOSITE is used, a section definition, *SECTION_SHELL or *SECTION_TSHELL, and integration rule definition, *INTEGRATION_SHELL, are unnecessary. Using *PART_COMPOSITE, the user specifies layer thicknesses, and integration points reside at the mid-points of layers. Integration is by the trapezoidal rule. So while *PART_COMPOSITE is more straightforward than *INTEGRATION_SHELL, it does not offer the same generality as *INTEGRATION_SHELL in terms of defining an integration rule.

The material ID, thickness, material angle and thermal material ID for each through-thickness integration point of a composite shell or thick shell are provided in the input for this command. The total number of integration points is determined by the number of entries on these cards.

Unless the *ELEMENT_SHELL_THICKNESS card is set, the thickness is assumed to be constant on each shell element. The thickness, then, is given by summing the THICK i values from card 4 below over the integration points i . When the *ELEMENT_SHELL_THICKNESS card is included, the THICK i values are scaled to fit the nodal thickness values assigned using the *ELEMENT_SHELL_THICKNESS keyword. For thick shells, the total thickness is obtained from the positions of the nodes on the top and bottom surfaces. In this case, the THICK i are also scaled to conform to the geometry defined by the element's nodes.

For a more general method of defining composite shells and thick shells, see *ELEMENT_SHELL_COMPOSITE and *ELEMENT_TSHELL_COMPOSITE. These commands permit unique layer stack-ups for each element without requiring a unique part ID for each element.

With *PART_COMPOSITE, two integration points with 4 constants each are provided in each [Integration Point Properties Card](#). With the LONG option, namely *PART_COMPOSITE_LONG, for each integration point there is one Integration Point

Properties Card. The LONG option can also be used with *PART_COMPOSITE_-TSHELL.

To maintain a direct association of through-thickness integration point numbers with physical plies in the case where plies span over more than one part ID, see [Remark 5](#).

The CONTACT option allows part based contact parameters to be used with the automatic contact types a3, 4, a5, a10, 13, a13, 15 and 26, which are listed under the *PART definition above.

Card Summary:

Card 1. This card is required.

| HEADING | | | | | | | |
|---------|--|--|--|--|--|--|--|
|---------|--|--|--|--|--|--|--|

Card 2a. This card is included if and only if the TSHELL option is *not* used.

VARIABLE**DESCRIPTION**

PID Part ID

ELFORM Element formulation options for thin shells:

- EQ.1: Hughes-Liu,
- EQ.2: Belytschko-Tsay,
- EQ.3: BCIZ triangular shell,
- EQ.4: C^0 triangular shell,
- EQ.6: S/R Hughes-Liu,
- EQ.7: S/R co-rotational Hughes-Liu,
- EQ.8: Belytschko-Leviathan shell,
- EQ.9: Fully integrated Belytschko-Tsay membrane,

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | EQ.10: Belytschko-Wong-Chiang, EQ.11: Fast (co-rotational) Hughes-Liu, EQ.16: Fully integrated shell element (very fast) |
| SHRF | Shear correction factor which scales the transverse shear stress. |
| NLOC | Location of reference surface, available for thin shells only. If nonzero, the offset distance from the plane of the nodal points to the reference surface of the shell in the direction of the shell normal vector is a value: $\text{offset} = -0.50 \times \text{NLOC} \times (\text{average shell thickness}).$ This offset is not considered in the contact subroutines unless CNTCO is set to 1 in *CONTROL_SHELL. Alternatively, the offset can be specified by using the OFFSET option in the *ELEMENT_SHELL input section. EQ.1.0: top surface, EQ.0.0: mid-surface (default), EQ.-1.0: bottom surface. |
| MAREA | Non-structural mass per unit area. This is additional mass which comes from materials such as carpeting. This mass is not directly included in the time step calculation. |
| HGID | Hourglass/bulk viscosity identification defined in the *HOURLASS Section: EQ.0: default values are used. |
| ADPOPT | Indicate if this part is adapted or not. Also see, *CONTROL_ADAPTIVITY: EQ.0: no adaptivity, EQ.1: <i>h</i> -adaptive for 3-D thin shells. |
| THSHEL | Thermal shell formulation EQ.0: Default is governed by THSHEL on *CONTROL_SHELL EQ.1: Thick thermal shell EQ.2: Thin thermal shell |

Thick Shell Card. This is an additional card for the TSHELL option.

| Card 2b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|------|---|---|------|---|--------|
| Variable | PID | ELFORM | SHRF | | | HGID | | TSHEAR |
| Type | I | I | F | | | I | | I |
| Default | none | none | 1.0 | | | 0 | | 0 |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| PID | Part ID |
| ELFORM | Element formulation options for thick shells: EQ.1: one point reduced integration, EQ.2: selective reduced 2×2 in plane integration, EQ.3: assumed strain 2×2 in plane integration, EQ.5: assumed strain reduced integration with brick materials EQ.6: assumed strain reduced integration with shell materials EQ.7: assumed strain 2×2 in plane integration |
| SHRF | Shear correction factor which scales the transverse shear stress. |
| HGID | Hourglass/bulk viscosity identification defined in the *HOUR-GLASS Section: EQ.0: default values are used. |
| TSHEAR | Flag for transverse shear stress distribution (see Remarks 3 and 4): EQ.0: Parabolic, EQ.1: Constant through thickness. |

Contact Card. Additional Card is required for the CONTACT option.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|----|----|------|-----|-----|---|
| Variable | FS | FD | DC | VC | OPTT | SFT | SSF | |
| Type | F | F | F | F | F | F | F | |

NOTE: If FS, FD, DC, and VC are specified they will not be used unless FS is set to a negative value (-1.0) in the *CONTACT section. These frictional coefficients apply only to contact types:

SINGLE_SURFACE,
 AUTOMATIC_GENERAL,
 AUTOMATIC_SINGLE_SURFACE,
 AUTOMATIC_NODES_TO_...,
 AUTOMATIC_SURFACE_...,
 AUTOMATIC_ONE_WAY_...,
 ERODING_SINGLE_SURFACE

Default values are input via *CONTROL_CONTACT input.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| FS | Static coefficient of friction. The functional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact as $\mu_c = FD + (FS - FD)e^{-DC \times v_{rel} }$ |
| FD | Dynamic coefficient of friction. The functional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact as $\mu_c = FD + (FS - FD)e^{-DC \times v_{rel} }$ |
| DC | Exponential decay coefficient. The functional coefficient is assumed to be dependent on the relative velocity v_{rel} of the surfaces in contact as $\mu_c = FD + (FS - FD)e^{-DC \times v_{rel} }$ |

| VARIABLE | DESCRIPTION |
|----------|--|
| VC | Coefficient for viscous friction. This is necessary to limit the friction force to a maximum. A limiting force is computed $F_{lim} = VC \times A_{cont}$. A_{cont} being the area of the segment contacted by the node in contact. The suggested value for VC is to use the yield stress in shear $VC = \sigma_0 / \sqrt{3}$ where σ_0 is the yield stress of the contacted material. |
| OPTT | Optional contact thickness. This applies to shells only. |
| SFT | Optional thickness scale factor for PART ID in automatic contact (scales true thickness). This option applies only to contact with shell elements. True thickness is the element thickness of the shell elements. |
| SSF | Scale factor on default slave penalty stiffness for this PART ID whenever it appears in the contact definition. If zero, SSF is taken as unity. |

Integration Point Data Cards without Long Option. The material ID, thickness, and material angle for each through-thickness integration point of a composite shell are provided below (up to two integration points per card). The integration point data should be given sequentially starting with the bottommost integration point. The total number of integration points is determined by the number of entries on these cards. Include as many cards as necessary. The next "*" card terminates this input.

| Card 4a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|----|-------|------|--------|----|-------|
| Variable | MID1 | THICK1 | B1 | TMID1 | MID2 | THICK2 | B2 | TMID2 |
| Type | I | F | F | I | I | F | F | I |

Integration Point Data Cards for Long Option. The material ID, thickness, and material angle for each through-thickness integration point of a composite shell are provided below (one integration point per card). The integration point data should be given sequentially starting with the bottommost integration point. The total number of integration points is determined by the number of entries on these cards. Include as many cards as necessary. The next "*" card terminates this input.

| Card 4b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|----|-------|--------|---------|---|---|
| Variable | MID1 | THICK1 | B1 | TMID1 | PLYID1 | SHRFAC1 | | |
| Type | I | F | F | I | I | F | | |

VARIABLE**DESCRIPTION**

| | |
|------------|--|
| MID i | Material ID of integration point i , see *MAT_... Section. |
| THICK i | Thickness of integration point i . |
| B i | Material angle of integration point i . This material angle applies only to material types 21, 22, 23, 33, 33_96, 34, 36, 40, 41-50, 54, 55, 58, 59, 103, 103_P, 104, 108, 116, 122, 133, 135, 135_PLC, 136, 157, 158, 190, 219, 226, 233, 234, 235, 242, and 243. |
| TMID i | Thermal material ID of integration point i |
| PLYID i | Ply ID of integration point i (for post-processing purposes) |
| SHRFAC i | Transverse shear stress scale factor |

Remarks:

- Orthotropic Materials.** In cases where there is more than one orthotropic material model referenced by *PART_COMPOSITE, the orthotropic material orientation parameters (AOPT, BETA, and associated vectors) from the material model of the first orthotropic integration point apply to all the orthotropic integration points. AOPT, BETA, etc. input for materials of subsequent integration points are ignored. B i , not to be confused with BETA, is applied into account for each integration point.
- SHRF Field and Zero Traction Condition.** Thick shell formulations 1, 2, and 3, and all shell formulations, except for BCIZ and DK elements, are based on first order shear deformation theory that yields constant transverse shear

strains which violates the condition of zero traction on the top and bottom surfaces of the shell. For these elements, setting $SHRF = 0.83333$ will compensate for this error and result in the correct transverse shear deformation, so long as all layers have the same transverse stiffness. $SHRF$ is not used by thick shell forms 3, 5, or 7 except for materials 33, 36, 133, 135, and 243.

3. **Thick Shell 5 or 6 and Shear Stress.** When thick shell formulation 5 and 6 are used, LS-Dyna will use either a parabolic transverse shear stress distribution when $TSHEAR = 0$ or a constant shear stress distribution when $TSHEAR = 1$. The parabolic option is recommended when elements are used in a single layer to model a plate or beam. The constant option may be better when elements are stacked so there are two or more elements through the thickness.
4. **Laminated Shear Stress Theory to Minimize Discontinuities.** For composites that have a transverse shear stiffness that varies by layer, laminated shell theory, activated by $LAMSHT$ on $*CONTROL_SHELL$, will correct the transverse shear stress to minimize stress discontinuities between layers and at the bottom and top surfaces by imposing a parabolic transverse shear stress. $SHRF$ should be set to the default value of 1.0 when the shear stress distribution is parabolic. If thick shells are stacked so that there is more than one element through the thickness of a plate or beam model, setting $TSHEAR = 1$ will cause a constant shear stress distribution which may be more accurate than parabolic. The $TSHEAR$ parameter is available for all thick shell forms when laminated shell theory is active. Alternatively, a scale factor can be defined for transverse shear stress in each layer of shell or thick shell composites using the $SHRFAC$ parameter. The inputted $SHRFAC$ values are normalized so that overall shear stiffness is unaffected by the distribution. Therefore, only the ratio of parameter values is significant.
5. **Assignment of Zero Thickness to Integration Points.** The ability to assign zero thickness integration points in the stacking sequence allows the number of integration points to remain constant even as the number of physical plies varies from part to part and eases post-processing since a particular integration point corresponds to a physical ply. Such a capability is important when one or more of the physical plies are not continuous across a composite structure. To represent a missing ply in $*PART_COMPOSITE$, set $THICK_i$ to 0.0 for the corresponding integration point and additionally, set either $MID = -1$ or, if the $LONG$ option is used, set $PLYID$ to any nonzero value.

When the number of physical plies varies from element to element in a part, one can assign zero thickness to integration points in exactly the same manner as described above but on an element-by-element basis using $*ELEMENT_SHELL_COMPOSITE_LONG$ or $*ELEMENT_TSHELL_COMPOSITE$.

When postprocessing the results using LS-PrePost version 4.5, read both the keyword deck and d3plot database into the code and then select *Option* → *N/A gray fringe*. Then, when viewing fringe plots for a particular integration point (*FriComp* → *Ipt* → *intpt#*), the element will be grayed out if the selected integration point is missing (or has zero thickness) in that element.

***PART_DUPLICATE_{OPTION}**

The available *OPTION* is:

<BLANK>

NULL_OVERLAY

NULL_OVERLAY is used to generate null shells for contact. See [Remark 5](#).

Purpose: To provide a method of duplicating parts or part sets without the need to use the *INCLUDE_TRANSFORM option.

Duplication Cards. This format is used when the keyword option is left <BLANK>. Include as many of these cards as desired. This input ends at the next keyword ("*") card.

| Card 1a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|--------|--------|--------|--------|--------|---|---|
| Variable | PTYPE | TYPEID | IDPOFF | IDEOFF | IDNOFF | TRANID | | |
| Type | A | I | I | I | I | I | | |
| Default | none | none | 0 | 0 | 0 | 0 | | |

Null Duplication Cards. This format is used when the keyword option is set to NULL_OVERLAY. Include as many of these cards as desired. This input ends at the next keyword ("*") card.

| Card 1b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|--------|--------|--------|---------|---|----|---|
| Variable | PTYPE | TYPEID | IDPOFF | IDEOFF | DENSITY | E | PR | |
| Type | A | I | I | I | F | F | F | |
| Default | none | none | 0 | 0 | 0 | 0 | 0 | |

VARIABLE

DESCRIPTION

PTYPE

Type of entity to duplicate:

EQ.PART: duplicate a single part

EQ.PSET: duplicate a part set

| VARIABLE | DESCRIPTION |
|-----------------|--|
| TYPEID | ID of part or part set to be duplicated |
| IDPOFF | ID offset of newly created parts |
| IDEOFF | ID offset of newly created elements |
| IDNOFF | ID offset of newly created nodes |
| TRANID | ID of *DEFINE_TRANSFORMATION to transform the existing nodes in a part or part set; see Remark 4 . |
| DENSITY | Density |
| E | Young's modulus |
| PR | Poisson's ratio |

Remarks:

1. **Parts with Common Nodes.** All parts sharing common nodes must be grouped in a *PART_SET and duplicated in a single *PART_DUPLICATE command so that the newly duplicated parts still share common nodes.
2. **Allowed Elements.** The following elements which need a *PART to complete their definition can be duplicated by using this command: *ELEMENT_SOLID, *ELEMENT_DISCRETE, *ELEMENT_SHELL, *ELEMENT_TSHELL, *ELEMENT_BEAM, and *ELEMENT_SEATBELT.
3. **Constraints.** This command only duplicates definition of nodes, elements and parts, not the associated constraints. For example, TC and RC defined in *NODE will not be passed to the newly created nodes.
4. **Transformation.** When IDNOFF = IDPOFF = IDEOFF = 0, the existing part, or part set, will be transformed as indicated by TRANID; no new node or elements will be created.
5. **Null Elements.** The NULL_OVERLAY option may be used to generate 3 and 4-node null shell elements from the 6- and 8-node quadratic elements for use in contact. No additional nodes are generated.

***PART_MODES**

Purpose: Treat a part defined with *MAT_RIGID as a linearized flexible body (LFB) whereby deformations are calculated from mode shapes. Unlike superelements (*ELEMENT_DIRECT_MATRIX_INPUT), linearized flexible bodies are accurate for systems undergoing large displacements and large rotations.

Currently, linearized flexible bodies cannot share nodes with other linearized flexible bodies or rigid bodies; however, interconnections to other linearized flexible bodies or to rigid bodies can use the penalty joint option. The linearized flexible bodies are not implemented with the Lagrange multiplier joint option (see LMF in *CONTROL_RIGID).

The deformations are modeled using the modes shapes obtained experimentally or in a finite element analysis, e.g., NASTRAN .pch file or a LS-DYNA d3eigv or d3mode file. These files may contain a combination of normal modes, constraint modes, and attachment modes. For stress recovery in linearized flexible bodies, use of linear element formulations is recommended. A lump mass matrix is assumed in the implementation. See also *CONTROL_RIGID.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|------|------|-------|--------|--------|-------|--------|
| Variable | PID | NMFB | FORM | ANSID | FORMAT | KMFLAG | NUPDF | SIGREC |

| Type | I | I | I | I | I | I | I | I |
| Default | none | nont | none | nont | none | nont | none | nont |

Optional Modal Damping Cards. This input ends at the next keyword ("**") card.

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|-------|-------|---|---|---|---|---|
| Variable | MSTART | MSTOP | DAMPF | | | | | |
| Type | I | I | F | | | | | |
| Default | none | none | none | | | | | |

VARIABLE**DESCRIPTION**

| | |
|--------|---|
| PID | Part identification. This part must be a rigid body. |
| NMFB | Number of kept modes in linearized flexible body. The number of modes in the file, FILENAME, must equal or exceed NMFB. If KMFLAG = 0 the first NMFB modes in the file are used. |
| FORM | Linearized flexible body formulation. See remark 5 below. EQ.0: exact EQ.1: fast EQ.2: general formulation EQ.3: general formulation without rigid body mode orthogonalization. |
| ANSID | Attachment node set ID (optional). |
| FORMAT | Input format of modal information: |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | EQ.0: NASTRAN.pch file. EQ.1: (not supported) EQ.2: NASTRAN.pch file (LS-DYNA binary version). The binary version of this file is automatically created if a NASTRAN.pch file is read. The name of the binary file is the name of the NASTRAN.pch file but with ".bin" appended. The binary file is smaller and can be read much faster. EQ.3: LS-DYNA d3eigv binary eigenvalue database (see *CONTROL_IMPLICIT_EIGENVALUE). EQ.4: LS-DYNA d3mode binary constraint/attachment mode database (see *CONTROL_IMPLICIT_MODE). |
| KMFLAG | Kept mode flag. Selects method for identifying modes to keep. This flag is not supported for FORMAT = 4 (d3mode). EQ.0: the first NMFB modes in the file, FILENAME, are used. EQ.1: define NMFB kept modes with additional input. |
| NUPDF | Nodal update flag. If active, an attachment node set, ANSID, must be defined. EQ.0: all nodes of the rigid part are updated each cycle. EQ.1: only attachment nodes are fully updated. All nodes in the body are output based on the rigid body motion without the addition of the modal displacements. For maximum benefit an attachment node set can also be defined with the PART_ATTACHMENT_NODES option. The same attachment node set ID should be used here. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| SIGREC | <p>Stress recovery flag.</p> <p>EQ.0: Do not recover stress.</p> <p>EQ.1: Recover stress.</p> <p>EQ.2: Recover stress and then set the recovery stress as initial stress when switching to a deformable body via *DEFORMABLE_TO_RIGID_AUTOMATIC. (shell formulations 16, 18, 20, 21 and solid formulation 2).</p> <p>EQ.3: Recover stress based on shell formulation 21, and then set the recovery stress as initial stress for shell formulation 16 when switching to a deformable body via *DEFORMABLE_TO_RIGID_AUTOMATIC (shell formulation 16 only).</p> |
| FILENAME | The path and name of a file which contains the modes for this rigid body. |
| MODE n | Keep normal mode, MODE n . |
| MSTART | First mode for damping, ($1 \leq \text{MSTART} \leq \text{NMFB}$). |
| MSTOP | Last mode for damping, MSTOP, ($1 \leq \text{MSTOP} \leq \text{NMFB}$). All modes between MSTART and MSTOP inclusive are subject to the same modal damping coefficient, DAMPF. |
| DAMPF | Modal damping coefficient, ζ . |

Remarks:

1. The format of the file which contains the normal modes follows the file formats of NASTRAN output for modal information.
2. The mode set typically combines both normal modes and attachment modes. The eigenvalues for the attachment modes are computed from the stiffness and mass matrices.
3. The part ID specified must be either a single rigid body or a master rigid body (see *CONSTRAINED_RIGID_BODIES) which can be made up of many rigid parts.
4. The modal damping is defined by the modal damping coefficient ζ , where a value of 1.0 equals critical damping. For a one degree of freedom model system, the relationship between the damping and the damping coefficient is

$c = 2\zeta\omega_n m$, where c is the damping, m is the mass, and ω_n is the natural frequency, $\sqrt{k/m}$.

5. There are four formulations. The first is a formulation that contains all the terms of the linearized flexible body equations, and its cost grows approximately as the square of the number of modes. The second formulation ignores most of the second order terms appearing in the exact equations and its cost grows linearly with the number of modes. If the angular velocities are small and if the deflections are small with respect to the geometry of the system, the cost savings of the second formulation may make it more attractive than the first method.

Please note that the first two formulations are only applicable when the modes are eigenmodes computed for the free-free problem, that is including the 6 rigid body modes. The third formulation, the default, is a more general formulation which allows more general mode shapes. The fourth formulation does not orthogonalize the modes with respect to the rigid body modes, and may allow boundary conditions to be imposed more simply in some cases than the third formulation. This last formulation is selected regardless of user input if attachment modes are used.

***PART_MOVE**

Purpose: Translate a part by an incremental displacement in either a local or a global coordinate system. This option currently applies to parts defined by either shell or solid elements. All nodal points of the given part ID are moved. Care must be observed since parts that share boundary nodes with the part being moved must also be moved to avoid severe mesh distortions – the variable IFSET can be used to handle the situation.

Part/Part Set Move Cards. Include as many of following cards as desired. This input ends at the next keyword (“*”) cards.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|----------|------|------|---|------|---|------|---|-----|-------|----|
| Variable | PID | XMOV | | YMOV | | ZMOV | | CID | IFSET | |
| Type | I | F | | F | | F | | I | I | |
| Default | none | 0.0 | | 0.0 | | 0.0 | | 0 | 0 | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| PID | Part or part set identification number. |
| XMOV | Move shell/solid part ID, PID, in the <i>x</i> -direction by the incremental distance, XMOV. |
| YMOV | Move shell/solid part ID, PID, in the <i>y</i> -direction by the incremental distance, YMOV. |
| ZMOV | Move shell/solid part ID, PID, in the <i>z</i> -direction by the incremental distance, ZMOV. |
| CID | Coordinate system ID to define incremental displacement in local coordinate system. All displacements, XMOV, YMOV, and ZMOV, are with respect to CID. EQ.0: global |
| IFSET | Indicate if part set ID is used in PID definition. EQ.0: part ID is used. EQ.1: part set ID is used. |

Remarks:

1. **Multiple Parts.** IFSET addresses the movement of multiple parts that share common boundary nodes, such as tailor-welded blanks. This field allows for all parts in a part set to move simultaneously.
2. **Draw Beads.** Draw beads can be modeled as beam elements that move the same distance and direction as either the die or punch, depending on the draw types.

Example:

The example partial deck given below automatically positions all tools in a toggle draw of a decklid inner, with a tailor welded blank consisting of PID 1 and PID5, as shown in [Figure 32-1](#). The keyword *CONTROL_FORMING_AUTOPOSITION_PARAMETER_SET calculates where to position various part sets as follows:

- a) the tailor-welded blank part set ID 1 is to be positioned in the global Z-direction on top of the lower die cavity (part set ID 4);
- b) the binder (part set ID 3) is to be positioned on top of the blank;
- c) the upper punch (part set ID 2) is to be positioned on top of the blank.

The three positioning distances for the blank, upper binder and upper punch are calculated and stored in variables &blnkmv, &upbinmv, and &uppunmv, respectively. The keyword *PART_MOVE, with IFSET set to 1, is responsible for moving the three part sets, using the three corresponding positioning variables. It is noted that the AUTOPOSITION keyword is only applicable to shell elements.

```

```

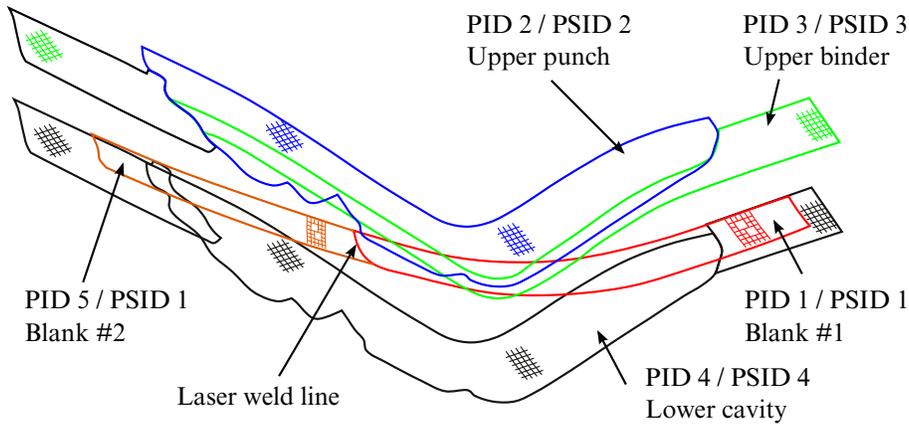

Figure 32-1. A tailer welded blank is positioned in a decklid (toggle draw).

Revision information:

This IFSET feature is available starting in LS-DYNA Revision #62935. It is also implemented in all the applicable stamping processes in LS-PrePost4.0 Metal Forming Application eZ-Setup (<http://ftp.lstc.com/anonymous/outgoing/lsprepost/4.0/metalforming/>).

***PART_SENSOR**

Purpose: Activate and deactivate parts, based on sensor defined in *ELEMENT_SEAT-BELT_SENSOR. This option applies to discrete beam element only.

Sensor Part Coupling Cards. Include as many of the following cards as desired. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|--------|---|---|---|---|---|
| Variable | PID | SIDA | ACTIVE | | | | | |
| Type | I | I | I | | | | | |
| Default | none | none | 0 | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| PID | Part ID which is controlled by sensor |
| SIDA | Sensor ID to activate or deactivate part |
| ACTIVE | Part activation flag: EQ.0: part is active from time zero until a signal is received by the part to deactivate. EQ.1: part is inactive from time zero and becomes active when a signal is received by the part to activate. The history variables for inactive parts are initialized at time zero. |

***PART_STACKED_ELEMENTS**

Purpose: This keyword provides a method of defining a stacked element model for shell-like structures. These types of plane load-bearing components possess a thickness which is small compared to their other (in-plane) dimensions. Their physical properties vary in the thickness direction according to distinct layers. Application examples include sandwich plate systems, composite laminates, plywood, and laminated glass.

With this keyword it is possible to discretize layered structures by an arbitrary sequence of shell and/or solid elements over the thickness. Whether a physical ply should be discretized by shell or solid elements depends on the individual thickness and other mechanical properties. Every single layer can consist of one shell element over the thickness or one or several solid elements over thickness.

The stacked element mesh can either be provided directly or it be automatically generated by LS-DYNA itself. For automatic generation extrusion methods are used to determine the new node locations that characterize the out-of-plane geometry. Each layer gets its own predefined properties such as individual thickness, material characteristic, and element type.

A more detailed description of this feature including a detailed description of the appropriate mesh generation procedure is given in Erhart [2015].

Layer Data Cards. The part ID, section ID, material ID, hourglass ID, thermal material ID, thickness, and number of through thickness solid elements for each layer i of a stacked element model are provided below. The layer data should be given sequentially starting with the bottommost layer. This card should be included NUMLAY times (one for each layer). The definitions in Card 3 replace the usual *PART cards.

| Type | I | I | I | I | I | F | I | |
| Default | none | none | none | 0 | 0 | none | none | |

VARIABLE**DESCRIPTION**

| | |
|----------|---|
| HEADING | Heading for the part composition. |
| PIDREF | Part ID of reference shell element mesh. |
| NUMLAY | Number of layers. |
| ADPOPT | Indicate if parts are adapted or not. (See also *CONTROL_ADAPTIVE): EQ.0: inactive EQ.1: h -adaptive refinement |
| INPLCMP | Option for in-plane composed parts: EQ.0: off EQ.1: on, see remark 6. |
| PID i | Part identification. |
| SID i | Section identification for layer i defined in a *SECTION keyword. |
| MID i | Material identification for layer i defined in a *MAT keyword. |
| HGID i | Hourglass identification for layer i defined in a *HOURGLASS keyword. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| TMID i | Thermal material identification for layer i defined in a *MAT_THERMAL keyword. |
| THK i | Thickness of layer i . |
| NSLD i | Number of through-thickness solid elements for layer i . |

Remarks:

- 1. Provided vs. Automatically Generated Meshes.** In general, there are two different options for this keyword:
 - a) The user provides a finished mesh comprising stacked shell and/or solid elements and then combines the corresponding part IDs using this keyword. This mode does not require a reference mesh in the PIDREF field nor does it require that either the layer thickness (THK i fields) and the number of through-thickness solids elements (NSLD i fields) be specified.
 - b) The user may provide a shell reference mesh (PIDREF) together with the layup sequence. The stacked element mesh is automatically generated during the initialization phase of LS-DYNA. In that second case, layer thickness (THK i) and number of through-thickness solids (NSLD i) must be defined.
- 2. Shell Solid Overlap.** In the mesh generation case, two consecutive layers (solid-solid or solid-shell) are firmly connected, meaning that they share nodes in the most obvious way possible (except they are both shell element layers, see [Remark 3](#) for that case). This condition leads to the necessity that shell and solid elements partly overlap if they follow each other in the stacking sequence. This deficiency can be corrected afterwards by subsequent relocation of the shell mid-surfaces via NLOC on *SECTION_SHELL (only works for first or last layer in this stacked element approach) or appropriate adjustment of the material stiffness for the solid elements.
- 3. Stacked Shells.** Starting with the release of LS-DYNA version R10, it is possible to define shell element layers directly on top of each other (i.e. without solid elements in between). A potential connection/interaction of such layers has to be declared separately by additional contact definitions (standard, tied, or tiebreak) otherwise they are free to penetrate each other.
- 4. Chained Calculations.** This keyword (*PART_STACKED_ELEMENTS) can also be used for modeling multi-stage processes. The *INTERFACE_SPRING-

BACK_LSDYNA card can be used to save a final state including deformed geometry, stresses, and strains to a `dynain` file. In a subsequent calculation the `*INCLUDE` keyword can be used with that `dynain` to apply the layup sequence without regenerating the mesh. LS-DYNA automatically detects if a reference shell element mesh is present or not.

5. **Example.** An example specifying a three layer shell-solid-shell structure is given below:

```
*PART_STACKED_ELEMENTS
$ title
sandwich

```

A sandwich structure is discretized by shell elements (SID = 200) on the outer layers with part identifiers 100 and 102. The interior of the “sandwich” consists of three solid elements (SID = 201, NSLD = 3) part identifier 101. In this case, the reference shell mesh belongs to part 11 (PIDREF). The thickness of each layer is defined by the value of the THK field, which will overwrite the thickness values from `*SECTION_SHELL`. Related materials (MID, TMID) and hourglass types (HGID) are treated as usual and therefore not shown here.

6. **In-Plane Composed Parts.** If the reference mesh is made up of several parts with matching nodes at their boundaries (e.g. tailor welded blanks), one `*PART_STACKED_ELEMENTS` must be defined for each reference part and option `INPLCMP` should be set to 1 for all of them. In addition, it is necessary to define `*NODE_MERGE_SET` for the newly generated parts, so that they stay together after new mesh generation.

***PARTICLE_BLAST**

Purpose: To define control parameters for particle based blast loading.

VARIABLE**DESCRIPTION**

| | |
|----------|--|
| LAGSID | Structure id for particle structure interaction |
| LAGSTYPE | Structure type EQ.0: Part Set EQ.1: Part |
| NODID | Discrete element sphere (DES) or Smooth particle hydrodynamics (SPH) id for the interaction between particles and nodes. |
| NODTYPE | Nodal type EQ.0: Node Set EQ.1: Node EQ.2: Part Set EQ.3: Part |
| HECID | Initial container for high explosive particle |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| HECTYPE | Structure type EQ.0: Part Set EQ.1: Part EQ.2: Geometry, see *DEFINE_PBLAST_GEOMETRY |
| AIRCID | Initial geometry for air particles EQ.0: filled air particles to entire domain defined by Card 5 GT.0: Reference to *DEFINE_PBLAST_AIRGEO ID |
| NPHE | Number of high explosive particles |
| NPAIR | Number of air particles |
| IUNIT | Unit System EQ.0: Kg-mm-ms-K EQ.1: SI Units EQ.2: Ton-mm-s-K EQ.3: g-cm-us-K EQ.4: blob-in-s-K: Where, $[\text{blob}] = \frac{[\text{lbf}][\text{s}]^2}{[\text{in}]}$ |
| IHETYPE | High Explosive type (See Remark 1) EQ.1: TNT EQ.2: C4 Others: Self Define |
| DENSITY | High Explosive density |
| ENERGY | High Explosive energy per unit volume |
| GAMMA | High Explosive fraction between C_p and C_v |
| COVOL | High Explosive co-volume |
| DET_V | High Explosive detonation velocity |
| DETX | Detonation point x |
| DETY | Detonation point y |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| DETZ | Detonation point z |
| TDET | Detonation time |
| BTEND | Blast end time |
| NID | An optional node ID defining the position of the detonation point. If defined, its coordinates will overwrite the DETX, DETY, and DETZ defined above. |
| BCX0 | Global domain x -min |
| BCX1 | Global domain x -max |
| BCY0 | Global domain y -min |
| BCY1 | Global domain y -max |
| BCZ0 | Global domain z -min |
| BCZ1 | Global domain z -max |
| IBCX0 | Boundary conditions for global domain x -min EQ.0: Free EQ.1: Rigid reflecting boundary |
| IBCX1 | Boundary conditions for global domain x -max EQ.0: Free EQ.1: Rigid reflecting boundary |
| IBCY0 | Boundary conditions for global domain y -min EQ.0: Free EQ.1: Rigid reflecting boundary |
| IBCY1 | Boundary conditions for global domain y -max EQ.0: Free EQ.1: Rigid reflecting boundary |

| VARIABLE | DESCRIPTION |
|----------|---|
| IBCZ0 | Boundary conditions for global domain z-min EQ.0: Free EQ.1: Rigid reflecting boundary |
| IBCZ1 | Boundary conditions for global domain z-max EQ.0: Free EQ.1: Rigid reflecting boundary |
| BC_P | Pressure ambient boundary condition for global domain EQ.0: Off (Default) EQ.1: On (Remark 2) |

Remarks:**1. Common Material Constants for commonly used High Explosives.**

| IHETYPE | ρ | e_0 | γ | COV | D |
|---------|-------------------------------------|----------------------------------|----------|-----|----------------------------------|
| TNT | $1630 \frac{\text{kg}}{\text{m}^3}$ | $7 \frac{\text{GJ}}{\text{m}^3}$ | 1.35 | 0.6 | $6930 \frac{\text{m}}{\text{s}}$ |
| C4 | $1601 \frac{\text{kg}}{\text{m}^3}$ | $9 \frac{\text{GJ}}{\text{m}^3}$ | 1.32 | 0.6 | $8193 \frac{\text{m}}{\text{s}}$ |

2. **Pressure Boundary Conditions.** If pressure boundary conditions are used, particles will not escape from the global domain when the pressure in the domain is lower than the ambient. The ambient is automatically assumed as 1 ATM by default inside LS-DYNA.

***PERTURBATION**

The keyword *PERTURBATION provides a means of defining deviations from the designed structure such as buckling imperfections. These perturbations can be viewed in LS-PrePost as user-defined fringe plots. Available options are:

*PERTURBATION_MAT

*PERTURBATION_NODE

*PERTURBATION_SHELL_THICKNESS

*PERTURBATION_OPTION

Available options are:

MAT

NODE

SHELL_THICKNESS

Purpose: Define a perturbation (stochastic field) over the whole model or a portion of the model, typically to trigger an instability. The NODE option modifies the three-dimensional coordinates for the whole model or a node set. For the SHELL_THICKNESS option, the shell thicknesses are perturbed for the whole model or a shell set. The MAT option perturbs a material parameter value for all the elements associated with that material.

Card Summary:

Card 1a. This card is included if and only if the MAT option is used.

| Default | 1 | {all} | 1.0 | 0 | 0 | | | |

| VARIABLE | DESCRIPTION |
|----------|--|
| TYPE | Type of perturbation EQ.1: Harmonic Field (see Remark 3) EQ.2: Fade out all perturbations at this element set (see Remark 4) EQ.3: Read perturbations from a file EQ.4: Spectral field |
| EID | Element set ID. Specify 0 to perturb all the elements in the model. |
| SCL | Scale factor |
| ICCOORD | Coordinate system to use; see Remarks 7, 8 and 9 EQ.0: Global Cartesian |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | EQ.1: Cartesian |
| | EQ.2: Cylindrical (computed and applied) |
| | EQ.3: Spherical (computed and applied) |
| | EQ.-2: Computed in cartesian but applied in cylindrical |
| | EQ.-3: Computed in cartesian but applied in spherical |
| CID | Coordinate system ID; see *DEFINE_COORDINATE_NODES. |

Harmonic Perturbation Cards (TYPE = 1). Card format 2 for TYPE = 1. Include as many cards of the following card as necessary. The input ends at the next keyword ("*") card.

| Card 2a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|------|-----|------|-----|------|---|
| Variable | AMPL | XWL | XOFF | YWL | YOFF | ZWL | ZOFF | |
| Type | F | F | F | F | F | F | F | |
| Default | 1.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| AMPL | Amplitude of the harmonic perturbation |
| XWL | <i>x</i> wavelength of the harmonic field |
| XOFF | <i>x</i> offset of harmonic field |
| YWL | <i>y</i> wavelength of the harmonic field |
| YOFF | <i>y</i> offset of harmonic field |
| ZWL | <i>z</i> wavelength of the harmonic field |
| ZOFF | <i>z</i> offset of harmonic field |

PERTURBATION**PERTURBATION**

Fade Field Perturbation Card (TYPE = 2). Card format 2 for TYPE = 2. See [Remark 4](#).

| Card 2b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | FADE | | | | | | | |
| Type | F | | | | | | | |
| Default | 1.0 | | | | | | | |

VARIABLE**DESCRIPTION**

FADE

Parameter controlling the distance over which faded perturbations are faded (material perturbations are not faded).

Perturbation from File Card (TYPE = 3). Card format 2 for TYPE = 3.

| Card 2c | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

VARIABLE**DESCRIPTION**

CSTYPE

Correlation structure:

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | EQ.1: 3D isotropic. The x , y and z correlations are described using one correlation function. Define CFC1. |
| | EQ.2: 3D product. The x , y and z correlations are described using a correlation function each. Define CFC1, CFC2 and CFC3. |
| | EQ.3: 2D isotropic. A correlation function describes the x correlation while the yz isotropic relationship is described using another correlation function. Define CFC1 and CFC2. |
| | EQ.4: 2D isotropic. The xz isotropic relationship is described using a correlation function, while another correlation function describes the y correlation while. Define CFC1 and CFC2. |
| | EQ.5: 2D isotropic. The xy isotropic relationship is described using a correlation function, while another correlation function describes the z correlation while. Define CFC1 and CFC2. |
| | EQ.6: 3D elliptic. Define CSE1, CSE2 and CFC1. |
| | EQ.7: 2D elliptic. A correlation function describes the x correlation while the yz elliptic relationship is described using another correlation function. Define CSE1 and CFC1. |
| | EQ.8: 2D elliptic. A correlation function describes the y correlation while the zx elliptic relationship is described using another correlation function. Define CSE1 and CFC1. |
| | EQ.9: 2D elliptic. The xy elliptic relationship is described using a correlation function, while another correlation function describes the z correlation while. Define CSE1 and CFC1. |
| ELLIP1 | Elliptic constant for 2D and 3D elliptic fields |
| ELLIP2 | Elliptic constant for 3D elliptic field |
| RND | Seed for random number generator. EQ.0: LS-DYNA will generate a random seed GT.0: Value to be used as seed |

Spectral Perturbation Parameter Cards. Include one, two, or three cards of this format, depending on the value of CSTYPE.

| Card 2d.1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-----------|--------|------|------|------|---|---|---|---|
| Variable | CSTYPE | CFC1 | CFC2 | CFC3 | | | | |
| Type | I | F | F | F | | | | |
| Default | none | 1.0 | 1.0 | 1.0 | | | | |

VARIABLE**DESCRIPTION**

CSTYPE Correlation function (see [Remark 6](#))
 EQ.1: Gaussian
 EQ.2: Exponential
 EQ.3: Exponential Cosine
 EQ.4: Rational
 EQ.5: Linear

CFC i Correlation function constant i

Remarks:

1. **Postprocessing.** The perturbation can be viewed in LS-PrePost. For the NODE option, LS-DYNA creates files named `pert_node_x/y/z/res`, which can be viewed as user-defined fringe plots. For the SHELL_THICKNESS and MAT options, the files are named `pert_shell_thickness` and `pert_mat` respectively. If a coordinate system with a radial component is used, then the file `pert_node_radial` is also written.
2. **Linear Combinations and Maximum Amplitudes.** Perturbations specified using separate *PERTURBATION cards are created separately and then added together. This is true as well for special cases, such as `CMP = 7` in which case the x , y and z fields are created separately and added together afterwards, which can result in an absolute amplitude greater than specified using `AMPL` or `SCL`.
3. **Harmonic Perturbations.** The harmonic perturbation is

$$p_{\text{CMP}}(x, y, z) = \text{SCL} \\ \times \text{AMPL} \times \left[\sin\left(2\pi \frac{x + \text{XOFF}}{\text{XWL}}\right) + \sin\left(2\pi \frac{y + \text{YOFF}}{\text{YWL}}\right) \right. \\ \left. + \sin\left(2\pi \frac{z + \text{ZOFF}}{\text{ZWL}}\right) \right]$$

Note that the harmonic perturbations can sum to values greater than $\text{SCL} \times \text{AMPL}$.

4. **Fade Perturbation.** The fade perturbation is

$$p'(x, y, z) = \text{SCL} \times \left(1 - \frac{1}{e^{\text{FADE}_{xx'}}}\right) p(x, y, z)$$

where x' is the shortest distance to a node in the node set or element set specified and FADE is the parameter controlling the sharpness of the fade perturbation.

5. **Keyword Format for FNAME Field.** The file FNAME must contain the perturbation in the LS-DYNA keyword format. This file can be created from the d3plot results using the LS-PrePost Output capability. The data must be arranged into two columns with the first column being the node ids. Lines starting with the character \$ will be ignored.
6. **Correlation Functions.** The correlation functions are defined as follows:

- a) Gaussian: $B(t) = e^{-(at)^2}$
- b) Exponential: $B(t) = e^{-|at|^b}$
- c) Exponent and Cosine: $B(t) = e^{-|at|} \cos(bt)$
- d) Rational: $B(t) = (1 + |at|^b)^{-c}$
- e) Piecewise Linear: $B(t) = (1 - |at|)\chi(1 - |at|)$

with χ the Heaviside step function and a , b and c corresponding to CFC1, CFC2 and CFC3, respectively.

7. **Cylindrical Coordinates.** For the cylindrical coordinate system option (ICOORD = 2), the default is to use the global coordinate system for the location of the cylindrical part, with the base of the cylinder located at the origin, and the global z-axis aligned with the cylinder axis. For cylindrical parts not located at the global origin, define a coordinate system (numbered CID) using *DEFINE_COORDINATE_NODES by selecting any three nodes on the base of the cylinder in a clockwise direction (resulting in the local z-axis to be aligned with the cylinder).

8. **Spherical Coordinates.** For the spherical coordinate system ($ICCOORD = 3$), the coordinates are the radius, zenith angle $[0, \pi]$, and the azimuth angle $[0, 2\pi]$. The default is to use the global coordinate system with the zenith measured from the z -axis and the azimuth measured from the x -axis in the xy -plane. For spherical parts not located at the global origin, define a coordinate system using `*DEFINE_COORDINATE_NODES` by selecting any three nodes as follows: the first node is the center of the sphere, the second specifies the x -axis of the coordinate system, while the third point specifies the plane containing the new y -axis. The z -axis will be normal to this plane.
9. **Computed in Cartesian Applied to Cylindrical or Spherical.** It is possible to compute the perturbations in a Cartesian coordinate system, but to apply them in a cylindrical or spherical coordinate system ($ICCOORD = -2, -3$). This is the natural method of doing say a radial perturbation of a sphere using a spectral perturbation field. We expect that computing the perturbation in the spherical coordinate system should be rare ($ICCOORD = 3$). Computing a perturbation in a cylindrical coordinate system should be common though; for example, a circumferential harmonic perturbation.
10. **Material Perturbation Feature.** Only `*MAT_238` (`*MAT_PERT_PIECEWISE_LINEAR_PLASTICITY`) and solid elements in an explicit analysis can be perturbed using `*PERTURBATION_MAT`. See the documentation of this material for allowable components. Only one part per model can be perturbed. For some perturbed quantity c , the material perturbation is applied on an element-by-element basis as

$$c_{\text{new}} = (1 + p)c_{\text{base}}$$

where p is a random number, which is written to the `pert_mat` file during the calculation. Values of p less than -1 are not allowed because the material behavior is not defined.

Completely independent of `*PERTURBATION_MAT`, see `*DEFINE_STOCHASTIC_VARIATION` for a way to define a stochastic variation of yield stress and/or failure strain in material models 10, 15, 24, 81, and 98 and the shell version of material 123.

***RAIL**

Two keywords are defined in this section.

*RAIL_TRACK

*RAIL_TRAIN

***RAIL_TRACK**

Purpose: Wheel-rail contact algorithm intended for railway applications but can also be used for other purposes. The wheel nodes (defined on *RAIL_TRAIN) represent the contact patch between wheel and rail. A penalty method is used to constrain the wheel nodes to slide along the track. A track consists of two rails, each of which is defined by a set of beam elements.

Card Sets. For each track include one pair of Cards 1 and 2. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---------|--------|-------|-------|-----|-----|------|
| Variable | ID | BSETID1 | NORGN1 | LCUR1 | OSET1 | SF1 | GA1 | IDIR |
| Type | I | I | I | I | F | F | F | I |
| Default | none | none | none | ↓ | 0.0 | 1.0 | 0.0 | 0 |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---|---------|--------|-------|-------|-----|-----|---|
| Variable | | BSETID2 | NORGN2 | LCUR2 | OSET2 | SF2 | GA2 | |
| Type | | I | I | I | F | F | F | |
| Default | | none | none | ↓ | 0.0 | 1.0 | 0.0 | |

VARIABLE**DESCRIPTION**

| | |
|-----------|---|
| ID | Track ID |
| BSETID1,2 | Beam set ID for rails 1 and 2 containing all beam elements that make up the rail; see *SET_BEAM. |
| NORGN1,2 | Reference node at one end of each rail, used as the origin for the roughness curve. The train will move in a direction away from this node. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| LCUR1,2 | Load curve ID (see *DEFINE_CURVE) defining track roughness (vertical displacement from line of beam elements) of the rail as a function of distance from the reference node NORIGIN. Distance from reference node on x -axis of curve, roughness on y -axis. Default: no roughness. |
| OSET1,2 | Origin of curve LCUR is shifted by distance OSET towards the reference node. |
| SF1,2 | Roughness values are scaled by SF. Default: 1.0. |
| GA1,2 | Shear stiffness of rail per unit length (used to calculate local rail shear deformation within each beam element). $GA = \text{shear modulus} \times \text{cross-sectional area}$. Default: local shear deformation is ignored. |
| IDIR | Determines which way is “up” for purposes of wheel/rail contact. Vertical contact works like a normal penalty-based contact while horizontal contact follows Figure 35-2 . <p>EQ.0: (Default) global z is “up” and the global xy-plane is assumed horizontal irrespective of the geometry of the rails.</p> <p>EQ.1: “Up” is the normal vector to the plane containing the 2 rails, given by the vector \mathbf{c} where $\mathbf{c} = \mathbf{a} \times \mathbf{b}$, \mathbf{a} is the direction along rail 1 heading away from node NORGN1 and \mathbf{b} is the vector from rail 1 to rail 2. Both \mathbf{a} and \mathbf{b} are determined locally at the contact point.</p> <p>EQ.-1: Same as IDIR = 1 except “up” is along $-\mathbf{c}$.</p> |

Remarks:

*RAIL_TRACK and *RAIL_TRAIN were written by Arup to represent wheel-rail contact. They have been used to generate loading on models of bridges for vibration predictions, for stress calculations, and for estimating accelerations experienced by passengers. Other non-railway uses are possible: the algorithm causes the “train” nodes to follow the line defined by the “rail” beam elements and transfers forces between them. In some cases (especially vibration modeling), double precision versions of LS-DYNA may give superior results because of the small relative deflections between wheel and rail.

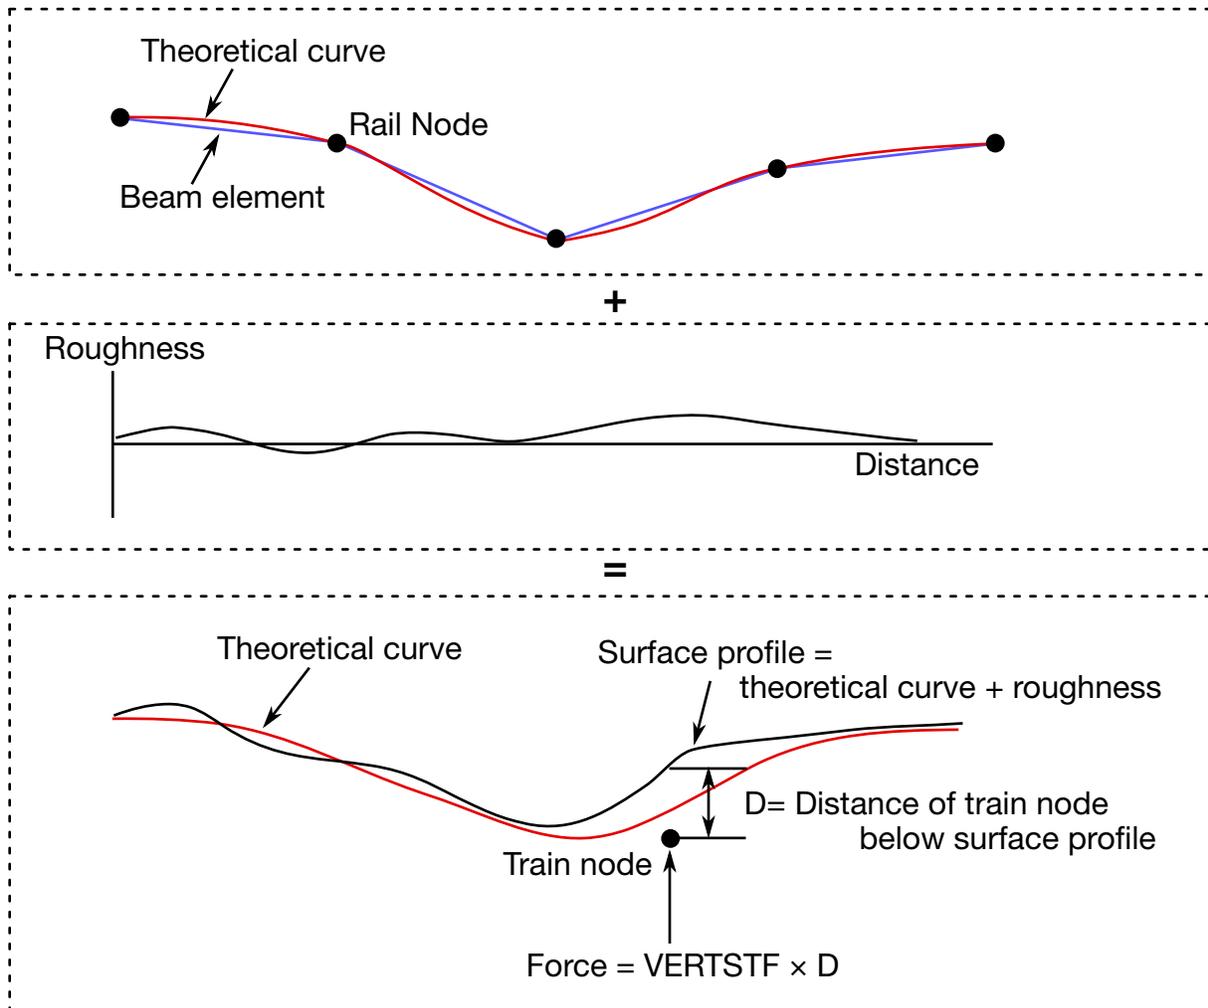

Figure 35-1. Track Model

Track Modeling:

The rails of the track should be modeled by two parallel lines of beam elements. The track can be curved or straight and the rails can be modeled as deformable or rigid. If required, rail pads, sleepers and ballast may also be modeled – typically with spring, damper and beam elements. It is also possible to use this algorithm to control the motion of simple road vehicle models: beam element “rails” made of null material can be embedded in the road surface. It is recommended that the mesh size of the two rails should be similar: LS-DYNA calculates a local coordinate system for each train node based on the alignment of the currently contacted beam element and the nearest node on the other rail.

Because wheel-rail contact stiffness is generally very high, and wheel masses are large, small deviations from a straight line or smooth curve can lead to large transient forces. It is recommended that great care be taken in generating and checking the geometry for

the track, especially where the track is curved. Some pre-processors write the coordinates with insufficient precision to the LS-DYNA input file which can cause unintended roughness in the geometry. For the same reason, if the line of the track were taken as straight between nodes, spurious forces would be generated when the wheel passes from one rail element to the next. This is avoided because the *RAIL algorithm calculates a theoretical curved centerline for the rail element to achieve continuity of slope from one element to the next. Where the length of the rail elements is similar to or shorter than the maximum section dimension, shear deformation may be significant, and it is possible to include this in the theoretical centerline calculation to further reduce spurious forces at the element boundaries (inputs GA1, GA2).

Roughness (small deviations in the vertical profile from a perfect straight line) does exist in real life and is a principal source of vibration. *RAIL allows the roughness to be modeled by a load curve giving the vertical deviation (in length units) of the rail surface from the theoretical centerline of the beam elements as a function of distance along the track from the origin node of the rail. The roughness curve is optional. Ideally, roughness profiles measured from both rails of the same piece of track should be used so that the relationship between bump and roll modes is correctly captured.

Whether roughness is included or not, it is important to select as the origin nodes (NORIGIN1 and NORIGIN2) the nodes at the end of the rails away from which the train will be traveling. The train can start at any point along the rails but must travel away from the origin nodes.

Train Modeling:

The vehicles are typically modeled using spring, damper and rigid elements, or simply a point mass at each wheel position. Each node in the set referred to on *RAIL_TRAIN represents the contact patch of one wheel (note: not the center of the wheel). These nodes should be initially on or near the line defined by either of the two rails. LS-DYNA will move the train nodes initially onto the rails to achieve the correct initial wheel-rail forces. If the results are viewed with magnified displacements, the initial movements can appear surprising.

Wheel roughness input is available. This will be applied in addition to track roughness. The input curve must continue for the total rolled distance – it is not assumed to repeat with each wheel rotation. This is to avoid problems associated with ensuring continuity between the start and end of the profile around the wheel circumference, especially since the profiles might be generated from roughness spectra rather than taken directly from measured data.

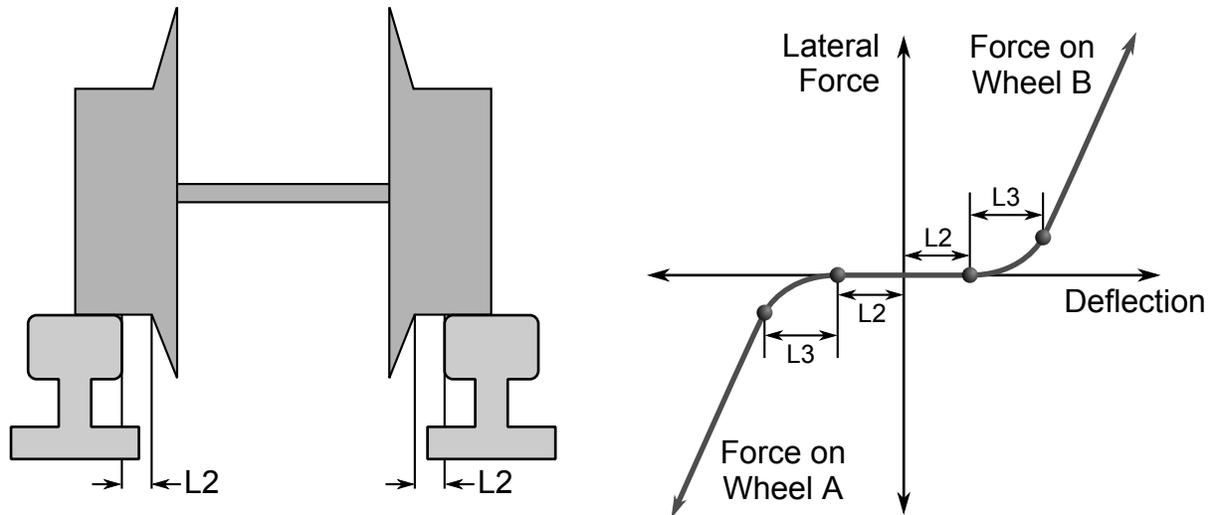

Figure 35-2. Illustration of lateral drift parameters L2 and L3 from *RAIL_TRACK.

Wheel-Rail Interface:

The wheel-rail interface model is a simple penalty function designed to ensure that the train nodes follow the line of the track. It does not attempt to account for the shape of the rail profile. Vertical and lateral loads are treated independently. For this reason, the algorithm is not suitable for rail vehicle dynamics calculations.

Wheel-rail contact stiffness is input on *RAIL_TRAIN. For vertical loads, a linear force-deflection relationship is assumed in compression; no tensile force is generated (this corresponds to the train losing contact with the rail). Typical contact stiffness is 2 MN/mm. Lateral deflections away from the theoretical centerline of the rail beams are also penalized by a linear force-deflection relationship. The lateral force is applied only to wheels on the side towards which the train has displaced (corresponding to wheel flanges that run inside the rails).

Optionally, a “gap” can be defined in input parameter L2 such that the wheel set can drift laterally by L2 length units before any lateral force is generated. A further option is to allow smooth transition between “gap” and “contact” by means of a transition distance input as parameter L3. [Figure 35-2](#) illustrates the geometry of parameters L2 and L3.

Generally, with straight tracks a simple linear stiffness is sufficient. With curved tracks, a reasonable gap and transition distance should be defined to avoid unrealistic forces being generated in response to small inaccuracies in the distance between the rails. Gravity loading is expected, in order to maintain contact between rail and wheel. This is normally applied by an initial phase of dynamic relaxation. To help achieve convergence quickly, or in some cases avoid the need for dynamic relaxation altogether,

the initial force expected on each train node can be input (field FINIT on *RAIL_TRAIN). LS-DYNA positions the nodes initially such that the vertical contact force will be FINIT at each node. If the suspension of the rail vehicles is modeled, it is recommended that the input includes carefully calculated pre-compression of the spring elements; if this is not done, achieving initial equilibrium under gravity loading can be very time consuming.

The *RAIL algorithm ensures that the train follows the rails, but does not provide forward motion. This is generally applied using *INITIAL_VELOCITY, or for straight tracks, *BOUNDARY_PRESCRIBED_MOTION.

Output:

LS-DYNA generates an additional ASCII output file `train_force_n`, where `n` is an integer updated to avoid overwriting any existing files. The file contains the forces on each train node, output at the same time intervals as the binary time history file (DT on *DATABASE_BINARY_D3THDT).

Checking:

It is recommended that track and train models be tested separately before adding the *RAIL cards. Check that the models respond stably to impulse forces and that they achieve equilibrium under gravity loading. The majority of problems we have encountered have been due to unstable behavior of train or track. Often, these are first detected by the *RAIL algorithm and an error message will result.

***RAIL_TRAIN**

Purpose: Define train properties. A train is defined by a set of nodes in contact with a rail defined by *RAIL_TRACK.

Card Sets. For each train include one pair of Cards 1 and 2. This input ends at the next keyword ("**") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|---------|-------|---------|------|------|------|
| Variable | ID | NSETID | (blank) | FINIT | (blank) | TRID | LCUR | OFFS |
| Type | I | I | | F | | I | I | F |
| Default | none | none | | 0.0 | | 0 | ↓ | 0.0 |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---------|--------|-----|-----|-----|-----|---|---|
| Variable | VERTSTF | LATSTF | V2 | V3 | L2 | L3 | | |
| Type | F | F | F | F | F | F | | |
| Default | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | | |

VARIABLE**DESCRIPTION**

| | |
|--------|---|
| ID | Train ID |
| NSETID | Node set ID containing all nodes that are in contact with rails. |
| FINIT | Estimate of initial vertical force on each wheel (optional) – speeds up the process of initial settling down under gravity loading. |
| TRID | ID of track for this train, see *RAIL_TRACK. |
| LCUR | Load curve ID (see *DEFINE_CURVE) containing wheel roughness (distance of wheel surface away from perfect circle) as a function of distance traveled. The curve does not repeat with each rotation of the wheel – the last point should be at a greater distance than the train is expected to travel. Default: no wheel roughness. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| OFFS | Offset distance used to generate different roughness curves for each wheel from the roughness curve LCUR. The curve is offset on the x -axis by a different whole number multiple of OFFS for each wheel. |
| VERTSTF | Vertical stiffness of rail contact. |
| LATSTF | Lateral stiffness of rail contact. |
| V2,V3 | Unused variables – leave blank. |
| L2 | Lateral clearance from rail to wheel rim. Lateral force is applied to a wheel only when it has moved more than L2 away from the other rail, that is, the wheel rims are assumed to be near the inner face of the rail. |
| L3 | Further lateral distance before full lateral stiffness applies (force-deflection curve follows a parabola up to this point). |

***RIGIDWALL**

Two keywords are used in this section to define rigid surfaces:

***RIGIDWALL_GEOMETRIC_OPTION_{OPTION}_{OPTION}}_{OPTION}**

***RIGIDWALL_PLANAR_{OPTION}_{OPTION}}_{OPTION}**

The RIGIDWALL option provides a simple way of treating contact between a rigid surface and nodal points of a deformable body, called slave nodes. Slave nodes which belong to rigid parts are not, in general, checked for contact with only one exception. The RIGIDWALL_PLANAR option may be used with nodal points of rigid bodies if the planar wall defined by this option is fixed in space and the RWPNAL parameter is set to a positive nonzero value on the control card, *CONTROL_CONTACT.

When the rigid wall defined in this section moves with a prescribed motion, the equations of rigid body mechanics are not involved. For a general rigid body treatment with arbitrary surfaces and motion, refer to the *CONTACT_ENTITY definition. The *CONTACT_ENTITY option is for treating contact between rigid and deformable surfaces only.

Energy dissipated due to rigidwalls (sometimes called stonewall energy or rigid wall energy) is computed only if the parameter RWEN is set to 2 in *CONTROL_ENERGY.

The following keyword causes the forces acting on a rigid wall to be computed:

***RIGIDWALL_FORCE_TRANSDUCER**

*RIGIDWALL

*RIGIDWALL_FORCE_TRANSDUCER

*RIGIDWALL_FORCE_TRANSDUCER

Purpose: Define a force transducer for a rigid wall. The output of the transducer is written to the rwforc file.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|---|---|---|---|---|---|

| Remarks | 1 | | | | | | | |

VARIABLE

DESCRIPTION

HEADING Description for force transducer

Node Set Cards. For each node set add one card. This input ends at the next keyword ("**") card.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | NSID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

VARIABLE

DESCRIPTION

NSID Node set ID.

Remarks:

1. **Reporting for Node Set.** The forces acting on rigid wall RWID are reported separately for each NSID.
2. **Segment Option for Rigid Walls.** For rigid walls using the segment option, the forces acting on each segment are reported separately for each NSID.

***RIGIDWALL_GEOMETRIC_SHAPE_{OPTION}_{OPTION}_{OPTION}**

*RIGIDWALL_GEOMETRIC_SHAPE is a family of keywords all sharing common set of data cards and option flags. The available shape variants are:

*RIGIDWALL_GEOMETRIC_FLAT

*RIGIDWALL_GEOMETRIC_PRISM

*RIGIDWALL_GEOMETRIC_CYLINDER

*RIGIDWALL_GEOMETRIC_SPHERE

If prescribed motion is desired an additional option is available:

MOTION

One of the shape types [**FLAT, PRISM, CYLINDER, SPHERE**] must be specified, followed by the optional definition of **MOTION**, both on the same line with ***RIGIDWALL_GEOMETRIC**. If an ID number is specified, the additional option is available:

ID

If active, the ID card is the first card following the keyword. To view the rigid wall, the option:

DISPLAY

is available. With this option a rigid body is automatically defined which represents the shape, the physical position of the wall, and follows the walls motion if the **MOTION** option is active. Additional input is optional if **DISPLAY** is active.

For the **CYLINDER** and **SPHERE**, the option:

INTERIOR

is available. Nodes are confined to the interior of these geometric forms.

The order of the *OPTIONS* is arbitrary, that is, LS-DYNA will read ***RIGIDWALL_GEOMETRIC_SHAPE_MOTION_DISPLAY** the same as ***RIGIDWALL_GEOMETRIC_SHAPE_DISPLAY_MOTION**. However, the data cards have a strict order as indicated in the Card Summary.

Purpose: Define a rigid wall with an analytically described form. Four forms are possible. A prescribed motion is optional. For general rigid bodies with arbitrary surfaces and motion, refer to the ***CONTACT_ENTITY** definition. This option is for treating contact between rigid and deformable surfaces only.

Card Summary:

Card Sets. For each rigid wall include one set of the following data cards. This input ends at the next keyword ("*") card.

ID. First data card of the card set if the ID keyword option is used in the keyword name. Otherwise Card 1 is the first data card.

| | |
|------|---------|
| RWID | HEADING |
|------|---------|

Card 1. This card is required.

| | | | | | | | |
|------|--------|-------|-------|-------|--|--|--|
| NSID | NSIDEX | BOXID | BIRTH | DEATH | | | |
|------|--------|-------|-------|-------|--|--|--|

Card 2. This card is required.

| | | | | | | | |
|----|----|----|----|----|----|------|--|
| XT | YT | ZT | XH | YH | ZH | FRIC | |
|----|----|----|----|----|----|------|--|

Card 3a. This card is included only for the FLAT shape.

| | | | | | | | |
|------|------|------|------|------|--|--|--|
| XHEV | YHEV | ZHEV | LENL | LENM | | | |
|------|------|------|------|------|--|--|--|

Card 3b. This card is included only for the PRISM shape.

| | | | | | | | |
|------|------|------|------|------|------|--|--|
| XHEV | YHEV | ZHEV | LENL | LENM | LENP | | |
|------|------|------|------|------|------|--|--|

Card 3c. This card is included only for the CYLINDER shape.

| | | | | | | | |
|--------|--------|-------|--|--|--|--|--|
| RADCYL | LENCYL | NSEGS | | | | | |
|--------|--------|-------|--|--|--|--|--|

Card 3c.1. NSEGS instances of this card are included only for the CYLINDER shape.

| | | | | | | | |
|----|--------|--|--|--|--|--|--|
| VL | HEIGHT | | | | | | |
|----|--------|--|--|--|--|--|--|

Card 3d. This card is included only for the SPHERE shape.

| | | | | | | | |
|--------|--|--|--|--|--|--|--|
| RADSPH | | | | | | | |
|--------|--|--|--|--|--|--|--|

Card 4. This card is required if the MOTION keyword option is used.

| | | | | | | | |
|------|-----|----|----|----|--|--|--|
| LCID | OPT | VX | VY | VZ | | | |
|------|-----|----|----|----|--|--|--|

Card 5. This card is read only if the DISPLAY keyword option is used. It is optional and may be omitted unless more than one card set is being read in; if more than one card set is being used, then at least a blank line must be included for all but the last card set. If not input, the defaults will be used.

| | | | | | | | |
|-----|----|---|----|--|--|--|--|
| PID | RO | E | PR | | | | |
|-----|----|---|----|--|--|--|--|

Data Card Definitions:

ID Card. Additional card for ID keyword option. This heading is picked up by some of the peripheral LS-DYNA codes to aid in post-processing.

| ID | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---------|---|---|---|---|---|---|
| Variable | RWID | HEADING | | | | | | |
| Type | I | A70 | | | | | | |

VARIABLE**DESCRIPTION**

RWID

Rigid wall ID. This must be a unique number.

HEADING

Rigid wall descriptor. It is suggested that unique descriptions be used. This field can be left undefined.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|--------|-------|-------|---------|---|---|---|
| Variable | NSID | NSIDEX | BOXID | BIRTH | DEATH | | | |
| Type | I | I | I | F | F | | | |
| Default | {all} | {∅} | {∅} | 0. | 1.0E+20 | | | |

VARIABLE**DESCRIPTION**

NSID

Nodal set ID containing slave nodes; see **SET_NODE_OPTION*:
EQ.0: all nodes are slave to rigid wall.

NSIDEX

Nodal set ID containing nodes exempted as slave nodes; see **SET_NODE_OPTION*.

BOXID

If defined, only nodes in box are included as slave nodes to rigid wall.

BIRTH

Birth time of rigid wall. The time values of the load curves that control the motion of the wall are offset by the birth time.

| VARIABLE | DESCRIPTION | | | | | | | |
|-----------------|---|----|----|----|----|----|------|---|
| DEATH | Death time of rigid wall. At this time the wall is deleted from the calculation. If dynamic relaxation is active at the beginning of the calculation and if BIRTH = 0.0, the death time is ignored during the dynamic relaxation. | | | | | | | |
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | XT | YT | ZT | XH | YH | ZH | FRIC | |
| Type | F | F | F | F | F | F | F | |
| Default | 0. | 0. | 0. | 0. | 0. | 0. | 0. | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| XT | x -coordinate of tail of any outward drawn normal vector, \mathbf{n} , originating on wall (tail) and terminating in space (head); see Figure 36-1 . |
| YT | y -coordinate of tail of normal vector \mathbf{n} |
| ZT | z -coordinate of tail of normal vector \mathbf{n} |
| XH | x -coordinate of head of normal vector \mathbf{n} |
| YH | y -coordinate of head of normal vector \mathbf{n} |
| ZH | z -coordinate of head of normal vector \mathbf{n} |
| FRIC | Coulomb friction coefficient, except as noted below: EQ.0.0: frictionless sliding after contact, EQ.1.0: stick condition after contact. |

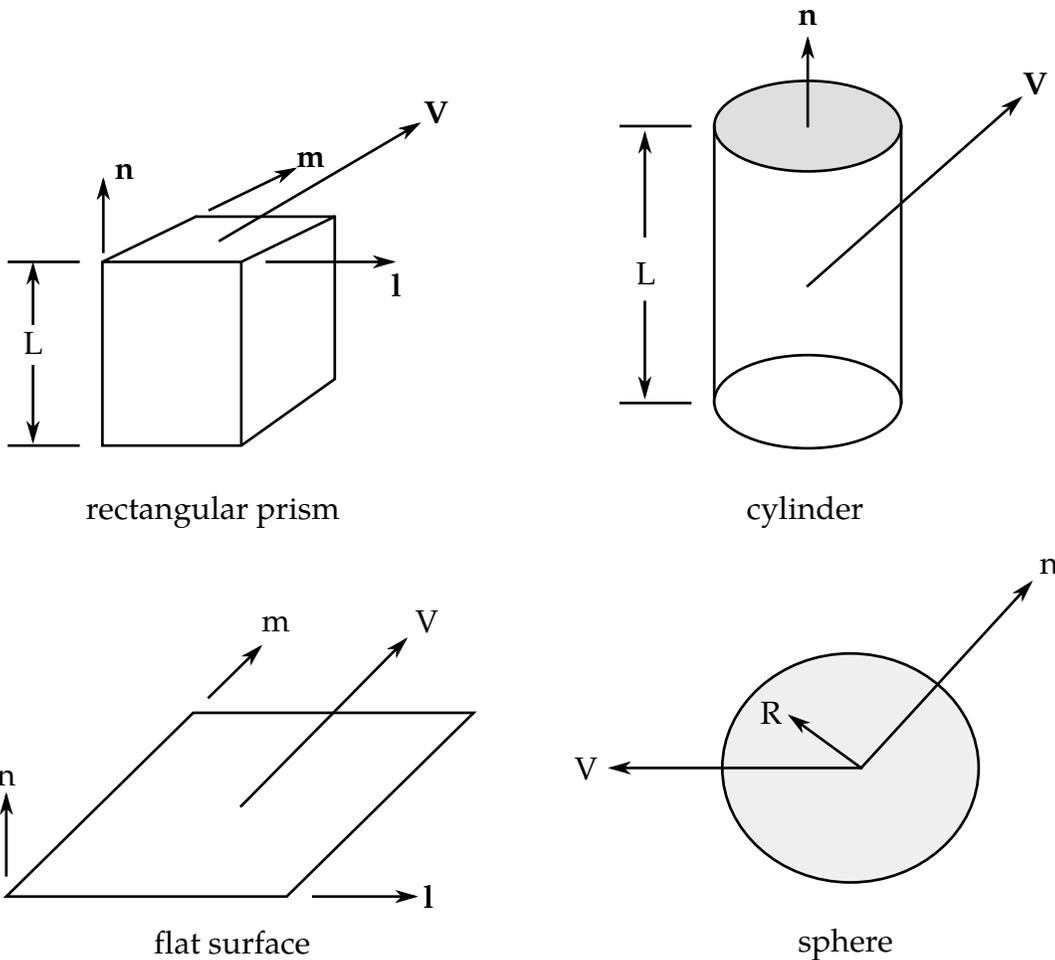

Figure 36-1. Vector \mathbf{n} determines the orientation of the rigidwall. By including the MOTION option, motion of the rigidwall can be prescribed in any direction \mathbf{V} as defined by variables VX, VY, VZ.

Flat Rigidwall Card. Card 3 for FLAT keyword option. A plane with a finite size or with an infinite size can be defined; see Figure 36-1. The vector \mathbf{m} is computed as the vector cross product $\mathbf{n} \times \mathbf{l}$. The origin, which is the tail (the start) of the normal vector, is the corner point of the finite size plane.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|----------|----------|---|---|---|
| Variable | XHEV | YHEV | ZHEV | LENL | LENM | | | |
| Type | F | F | F | F | F | | | |
| Default | 0. | 0. | 0. | infinity | infinity | | | |

| VARIABLE | DESCRIPTION |
|----------|---|
| XHEV | x -coordinate of head of edge vector l ; see Figure 36-1 . |
| YHEV | y -coordinate of head of edge vector l |
| ZHEV | z -coordinate of head of edge vector l |
| LENL | Length of l edge. A zero value defines an infinite size plane. |
| LENM | Length of m edge. A zero value defines an infinite size plane. |

Prismatic Rigidwall Card. Required card for PRISM keyword option that is input after Card 2. The description of the definition of a plane with finite size is enhanced by an additional length in the direction negative to **n**; see [Figure 36-1](#).

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|----------|----------|----------|---|---|
| Variable | XHEV | YHEV | ZHEV | LENL | LENM | LENP | | |
| Type | F | F | F | F | F | F | | |
| Default | none | 0. | 0. | infinity | infinity | infinity | | |

| VARIABLE | DESCRIPTION |
|----------|---|
| XHEV | x -coordinate of head of edge vector l , see Figure 36-1 . |
| YHEV | y -coordinate of head of edge vector l |
| ZHEV | z -coordinate of head of edge vector l |
| LENL | Length of l edge. A zero value defines an infinite size plane. |
| LENM | Length of m edge. A zero value defines an infinite size plane. |
| LENP | Length of prism in the direction negative to n ; see Figure 36-1 . |

Cylindrical Rigidwall Card. Required card for CYLINDER keyword option that is input after Card 2. The tail of **n** specifies the top plane of the cylinder. The length is defined in the direction negative to **n**. See [Figure 36-1](#).

| Card 5 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|----------|-------|---|---|---|---|---|
| Variable | RADCYL | LENCYL | NSEGS | | | | | |
| Type | F | F | I | | | | | |
| Default | none | infinity | 0 | | | | | |

VARIABLE**DESCRIPTION**

| | |
|--------|---|
| RADCYL | Radius of cylinder |
| LENCYL | Length of cylinder; see Figure 36-1 . Only if a value larger than zero is specified is a finite length assumed. |
| NSEGS | Number of subsections along cylinder to output forces for post-processing. The force vector for each subsection is output to <i>rwforc</i> . This gives a better idea of the force distribution along the length of the cylinder. |

NSEGS Card. If the Cylinder option is used, NSEGS of this card must be input after Card 5.

| Card 6 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|---|---|---|---|---|---|
| Variable | VL | HEIGHT | | | | | | |
| Type | F | F | | | | | | |
| Default | none | none | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| VL | Distance from the top plane of the cylinder where the subsection begins. |
| HEIGHT | Section height. The subsection starts at VL and extends the length, HEIGHT, in the <i>negative n</i> -direction. |

Spherical Rigidwall Card. Required card for SPHERE keyword option that is input after Card 2. The center of the sphere is identical to the tail (start) of **n**; see [Figure 36-1](#).

| Card 7 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|---|---|---|---|---|---|---|
| Variable | RADSPH | | | | | | | |
| Type | F | | | | | | | |
| Default | 0. | | | | | | | |

VARIABLE**DESCRIPTION**

RADSPH Radius of sphere

Motion Card. Additional card for MOTION keyword option.

| Card 8 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|------|------|------|---|---|---|
| Variable | LCID | OPT | VX | VY | VZ | | | |
| Type | I | I | F | F | F | | | |
| Default | none | 0 | none | none | none | | | |

VARIABLE**DESCRIPTION**

LCID Rigidwall motion curve ID; see *DEFINE_CURVE.

OPT Type of motion:
 EQ.0: velocity specified,
 EQ.1: displacement specified.

VX *x*-direction cosine of velocity/displacement vector

VY *y*-direction cosine of velocity/displacement vector

VZ *z*-direction cosine of velocity/displacement vector

***RIGIDWALL_PLANAR_{OPTION}_{OPTION}_{OPTION}**

Available options include:

<BLANK>

ORTHO

FINITE

MOVING

FORCES

The ordering of the input below as specified in the Card Summary must be observed, but the ordering of the options in the keyword name is unimportant. For example, both *RIGIDWALL_PLANAR_ORTHO_FINITE and *RIGIDWALL_PLANAR_FINITE_ORTHO are valid and have the same effect. The ORTHO option does not apply if the MOVING option is used.

An ID number may be assigned to the rigid wall using the following option:

ID

If this option is active, the ID card is the first card following the keyword.

Display of a non-moving, planar rigid wall is on by default (see SKIPRWG in *CONTROL_CONTACT). The option

DISPLAY

is available for display of moving rigid walls. With this option active, a rigid body is automatically created which represents the shape of the rigid wall and tracks its position without need for additional input. The part ID of the rigid body defaults to RWID if the ID option is active and RWID is a unique ID within the set of all part IDs.

Purpose: Define planar rigid walls with either finite (FINITE) or infinite size. Orthotropic friction can be defined (ORTHO). Also, the plane can possess a mass and an initial velocity (MOVING); otherwise, the wall is assumed to be stationary. The FORCES option allows the specification of segments on the rigid walls on which the contact forces are computed. For a more physical reaction related to the force as function of time curve, the SOFT value on the FORCES card can be specified.

Card Summary:

Card Sets. For each rigid wall matching the specified keyword options include one set of the following data cards. This input ends at the next keyword ("*") card.

Card ID. This card is included if and only if the ID keyword option is used.

| | | | | | | | |
|----|--|--|--|--|--|--|--|
| ID | | | | | | | |
|----|--|--|--|--|--|--|--|

Card 1. This card is required.

| | | | | | | | |

| Default | all nodes | { \emptyset } | { \emptyset } | 0. | 0. | 10 ²⁰ | 1.0 | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| NSID | Nodal set ID containing slave nodes; see *SET_NODE: EQ.0: all nodes are slave to rigid wall. |
| NSIDEX | Nodal set ID containing nodes that are exempted as slave nodes; see *SET_NODE. |
| BOXID | All nodes in box are included as slave nodes to rigid wall; see *DEFINE_BOX. If options NSID or NSIDEX are active, then only the subset of nodes activated by these options are checked to see if they are within the box. |
| OFFSET | All nodes within a normal offset distance, OFFSET, to the rigid wall are included as slave nodes for the rigid wall. If options NSID, NSIDEX, or BOXID are active, then only the subset of nodes activated by these options are checked to see if they are within the offset distance. |
| BIRTH | Birth time of rigid wall. The time values of the load curves that control the motion of the wall are offset by the birth time. |
| DEATH | Death time of rigid wall. At this time the wall is deleted from the calculation. If dynamic relaxation is active at the beginning of the calculation and BIRTH = 0.0, the death time is ignored during the dynamic relaxation. |
| RWKSF | Stiffness scaling factor. If RWKSF is also specified in *CONTROL_CONTACT, the stiffness is scaled by the product of the two values. |

Tail of normal vector is the origin and corner point if extent of stonewall is finite.

Figure 36-2. Vector \mathbf{n} is normal to the rigidwall. An optional vector \mathbf{l} can be defined such that $\mathbf{m} = \mathbf{n} \times \mathbf{l}$. The extent of the rigidwall is limited by defining L (LENL) and M (LENM). A zero value for either of these lengths indicates that the rigidwall is infinite in that direction.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|----|----|----|----|------|------|
| Variable | XT | YT | ZT | XH | YH | ZH | FRIC | WWEL |
| Type | F | F | F | F | F | F | F | F |
| Default | 0. | 0. | 0. | 0. | 0. | 0. | 0. | 0. |

VARIABLE

DESCRIPTION

- XT x -coordinate of tail of any outward drawn normal vector, \mathbf{n} , originating on wall (tail) and terminating in space (head), see [Figure 36-2](#).
- YT y -coordinate of tail of normal vector \mathbf{n}
- ZT z -coordinate of tail of normal vector \mathbf{n}
- XH x -coordinate of head of normal vector \mathbf{n}
- YH y -coordinate of head of normal vector \mathbf{n}

| VARIABLE | DESCRIPTION |
|----------|-------------|
|----------|-------------|

| | |
|----|--|
| ZH | z-coordinate of head of normal vector n |
|----|--|

| | |
|------|--|
| FRIC | <p>Coulomb friction coefficient except as noted below:</p> <p>EQ.0.0: frictionless sliding after contact,</p> <p>EQ.1.0: no sliding after contact,</p> <p>EQ.2.0: node is welded after contact with frictionless sliding. Welding occurs if and only if the normal value of the impact velocity exceeds the critical value specified by WVEL.</p> <p>EQ.3.0: node is welded after contact with no sliding. Welding occurs if and only if the normal value of the impact velocity exceeds the critical value specified by WVEL.</p> |
|------|--|

In summary, FRIC could be any positive value. Three special values of FRIC trigger special treatments as follows:

| FRIC | 1.0 | 2.0 | 3.0 |
|-------------------------|-------------|-------------|-------------|
| Bouncing back from wall | allowed | not allowed | not allowed |
| Sliding on wall | not allowed | allowed | not allowed |

| | |
|------|---|
| WVEL | Critical normal velocity at which nodes weld to wall (FRIC = 2 or 3). |
|------|---|

Orthotropic Friction Card 1. Additional card for ORTHO keyword option. See [Figure 36-3](#) for the definition of orthotropic friction.

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|--------|--------|--------|--------|---|---|
| Variable | SFRICA | SFRICB | DFRICA | DFRICB | DECAYA | DECAYB | | |
| Type | F | F | F | F | F | F | | |
| Default | 0. | 0. | 0. | 0. | 0. | 0. | | |

Orthotropic Friction Card 2. Additional card for ORTHO keyword option. See [Figure 36-3](#) for the definition of orthotropic friction.

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|----|----|----|---|---|---|
| Variable | NODE1 | NODE2 | D1 | D2 | D3 | | | |
| Type | I | I | F | F | F | | | |
| Default | 0 | 0 | 0. | 0. | 0. | | | |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| SFRICA | Static friction coefficient in local a -direction, μ_{sa} ; see Figure 36-3 and Remark 1 . |
| SFRICB | Static friction coefficient in local b -direction, μ_{sb} |
| DFRICA | Dynamic friction coefficient in local a -direction, μ_{ka} |
| DFRICB | Dynamic friction coefficient in local b -direction, μ_{kb} |
| DECAYA | Decay constant in local a -direction, d_{ya} |
| DECAYB | Decay constant in local b -direction, d_{yb} |
| NODE1 | Node 1, alternative to definition of vector \mathbf{d} using components below. See Figure 36-3 . With the node definition, the direction changes if the nodal pair rotates. See Remark 2 . |
| NODE2 | Node 2 |
| D1 | d_1 , x -component of vector, alternative to definition with nodes above. See Figure 36-3 . This vector is fixed as a function of time. See Remark 2 . |
| D2 | d_2 , y -component of vector |
| D3 | d_3 , z -component of vector |

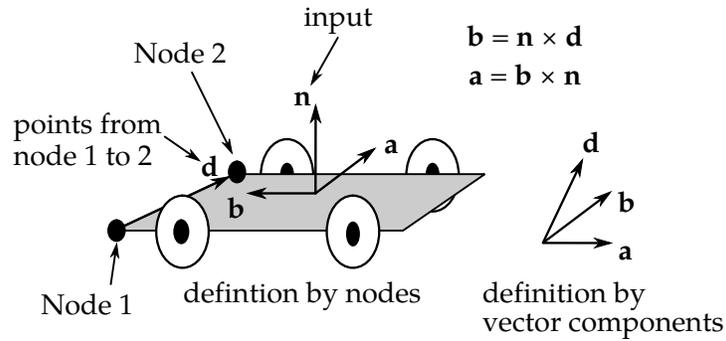

Figure 36-3. Definition of orthotropic friction vectors. The two methods of defining the vector, \mathbf{d} , are shown. If vector \mathbf{d} is defined by nodes 1 and 2, the local coordinate system may rotate with the body which contains the nodes; otherwise, \mathbf{d} is fixed in space, thus on the rigid wall, and the local system is stationary.

Finite Wall Size Card. Additional card for FINITE keyword option. See [Figure 36-3](#) for the definition of orthotropic friction. See [Figure 36-2](#). The \mathbf{m} vector is computed as the vector cross product $\mathbf{m} = \mathbf{n} \times \mathbf{l}$. The origin, the tail of the normal vector, is taken as the corner point of the finite size plane.

| Card 5 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|----------|----------|---|---|---|
| Variable | XHEV | YHEV | ZHEV | LENL | LENM | | | |
| Type | F | F | F | F | F | | | |
| Default | 0. | 0. | 0. | infinity | infinity | | | |

VARIABLE

DESCRIPTION

- XHEV x -coordinate of head of edge vector \mathbf{l} , see [Figure 36-2](#).
- YHEV y -coordinate of head of edge vector \mathbf{l}
- ZHEV z -coordinate of head of edge vector \mathbf{l}
- LENL Length of \mathbf{l} edge
- LENM Length of \mathbf{m} edge

Moving Wall Card. Additional card for MOVING keyword option. Note: The MOVING option is *not* compatible with the ORTHO option.

| Card 6 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|----|---|---|---|---|---|---|
| Variable | MASS | V0 | | | | | | |
| Type | F | F | | | | | | |
| Default | none | 0. | | | | | | |

VARIABLE**DESCRIPTION**

MASS

Total mass of rigidwall

V0

Initial velocity of rigidwall in direction of defining vector, **n**

Forces Card. Additional card for FORCES keyword option. This option allows the force distribution to be monitored on the plane. Also four points can be defined for visualization of the rigid wall. A shell or membrane element must be defined with these four points as the connectivity for viewing in LS-PREPOST.

| Card 7 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|---------|---------|---------|---------|---|---|
| Variable | SOFT | SSID | N1 | N2 | N3 | N4 | | |
| Type | I | I | I | I | I | I | | |
| Default | 0 | {Ø} | no node | no node | no node | no node | | |

VARIABLE**DESCRIPTION**

SOFT

Number of cycles to zero relative velocity to reduce force spike

SSID

Segment set ID for defining areas for force output; see *SET_SEGMENT and [Remark 3](#) below.

N1-N4

Optional node for visualization. See [Remark 4](#).

Remarks: Orthotropic Coefficients of Friction. The coefficients of friction are defined in terms of the static, dynamic and decay coefficients and the relative

*SECTION

In this section, the element formulation, integration rule, nodal thicknesses, and cross sectional properties are defined. All section identifiers (SECID's) defined in this section must be unique, i.e., if a number is used as a section ID for a beam element then this number cannot be used again as a section ID for a solid element. The keyword cards in this section are defined in alphabetical order:

*SECTION_ALE1D
*SECTION_ALE2D
*SECTION_BEAM_{*OPTION*}
*SECTION_DISCRETE
*SECTION_POINT_SOURCE
*SECTION_POINT_SOURCE_MIXTURE
*SECTION_SEATBELT
*SECTION_SHELL_{*OPTION*}
*SECTION_SOLID_{*OPTION*}
*SECTION_SPH_{*OPTION*}
*SECTION_TSHELL

The location and order of these cards in the input file are arbitrary.

An additional option **TITLE** may be appended to all the ***SECTION** keywords. If this option is used then an addition line is read for each section in 80a format which can be used to describe the section. At present, the title serves no purpose other than to perhaps lend clarity to input decks.

***SECTION_ALE1D**

Purpose: Define section properties for 1D ALE elements

Card Sets. For each ALE1D section add one pair of Cards 1 and 2. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---------|-----|--------|---|---|---|---|
| Variable | SECID | ALEFORM | AET | ELFORM | | | | |
| Type | I/A | I | I | I | | | | |
| Default | none | none | 0 | none | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|---|---|---|---|---|---|
| Variable | THICK | THICK | | | | | | |
| Type | F | F | | | | | | |
| Default | none | none | | | | | | |

VARIABLE**DESCRIPTION**

SECID

Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.

ALEFORM

ALE formulation:

EQ.11: Multi-Material ALE formulation.

AET

Ambient Element Type:

EQ.4: Pressure inflow

ELFORM

Element formulation:

EQ.7: Plane strain

EQ.8: Axisymmetric (per radian)

EQ.-8: spherical (per unit of solid angle)

| VARIABLE | DESCRIPTION |
|----------|---|
| THICK | Nodal thickness. See Remark 1 . |

Remarks:

1. **Nodal Thickness.** *SECTION_ALE1D is using the common *SECTION_BEAM reader which expects two thickness values. The ALE 1D will simply take the average of these two values as the beam thickness.

The thickness, however, is not used for ELFORM = -8, but the reader routine expects values on the 2nd line.

***SECTION_ALE2D**

Purpose: Define section properties for 2D ALE elements. This supersedes the old way of defining section properties for 2D ALE elements using *SECTION_SHELL.

Section Cards. For each ALE2D section include a card. This input terminates at the next keyword ("**") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---------|-----|--------|---|---|---|---|
| Variable | SECID | ALEFORM | AET | ELFORM | | | | |
| Type | I/A | I | I | I | | | | |
| Default | none | none | 0 | none | | | | |

VARIABLE**DESCRIPTION**

SECID

Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.

ALEFORM

ALE formulation:

EQ.11: Multi-Material ALE formulation.

AET

Part type flag:

EQ.0: This is a regular or non-ambient part (default)

EQ.4: Reservoir or ambient type part

EQ.5: Reservoir or ambient type part, but only used together with *LOAD_BLAST_ENHANCED (LBE). It defines this part as an "ambient receptor part" for the transient blast load supplied by a corresponding LBE KW (see *LOAD_BLAST_ENHANCED, available only for ALEFORM = 11).

ELFORM

Element formulation:

EQ.13: Plane strain (xy -plane)

EQ.14: Axisymmetric solid (xy -plane, y -axis of symmetry) – area weighted (see [Remark 2](#))

Remarks:

1. **Lagrangian-ALE Coupling.** For coupling between 2D Lagrangian elements and 2D ALE elements, use *CONSTRAINED_LAGRANGE_IN_SOLID rather than *CONTACT_2D_AUTOMATIC_SURFACE_IN_CONTINUUM.
2. **Axisymmetric Analysis.** For an axisymmetric analysis, ELFORM for *SECTION_ALE2D can only be set to 14 (area-weighted). In the same analysis, axisymmetric Lagrangian elements are not restricted to an area-weighted formulation. In other words, shell formulation 14 or 15 are permitted for Lagrangian shells and beam formulation 8 is permitted for Lagrangian beams. Coupling forces between the axisymmetric ALE elements and axisymmetric Lagrangian elements are automatically adjusted as needed.

*SECTION

*SECTION_BEAM

*SECTION_BEAM_{OPTION}

Available options include:

<BLANK>

AISC

such that the keyword cards appear:

*SECTION_BEAM

*SECTION_BEAM_AISC

Purpose: Define cross sectional properties for beam, truss, discrete beam, and cable elements.

The AISC option may be used to specify standard steel sections as specified by the American Institute of Steel Construction, and is described separately after *SECTION_BEAM

Card Sets. For each BEAM section in the model add one set of the following 2 (maybe 3 for ELFORM = 12) cards. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|--------|------|---------|-----|-------|-----|---|
| Variable | SECID | ELFORM | SHRF | QR/IRID | CST | SCOOR | NSM | |
| Type | I/A | I | F | F | F | F | F | |
| Default | none | 1 | 1.0 | 2.0 | 0.0 | 0.0 | 0.0 | |

Integrated Beam Card (types 1 and 11). Card 2 for ELFORM set to either type 1 or 11.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-------|-------|---|---|
| Variable | TS1 | TS2 | TT1 | TT2 | NSLOC | NTLOC | | |
| Type | F | F | F | F | F | F | | |

Resultant Beam With Shape Card (types 2, 3, and 12). Card 2 for ELFORM equal to 2, 3, or 12 and when first 7 characters of the card spell out "SECTION".

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|----|----|----|----|----|----|---|
| Variable | STYPE | D1 | D2 | D3 | D4 | D5 | D6 | |
| Type | A10 | F | F | F | F | F | | |

Resultant Beam Card 1 (types 2, 12, and 13). Card 2 for ELFORM equal to 2, 12, or 13 and when first 7 characters of card *do not* spell "SECTION".

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---|-----|-----|---|----|-----|-------|---|
| Variable | A | ISS | ITT | J | SA | IST | ITORM | |
| Type | F | F | F | F | F | F | F | |

Resultant Beam Card 2 (type 12 only). Card 3 for ELFORM equal to 12 and when first 7 characters of card 2 *do not* spell "SECTION".

| Card 3 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|-----|-----|-----|----|-----|---|
| Variable | YS | ZS | IYR | IZR | IRR | IW | IWR | |
| Type | F | F | F | F | F | F | F | |

Resultant Beam Card (type 3). Card 2 for ELFORM equal to 3.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---|-------|--------|---|---|---|---|---|
| Variable | A | RAMPT | STRESS | | | | | |
| Type | F | F | F | | | | | |

Integrated Beam Card (types 4 and 5). Card 2 for ELFORM equal to 4 or 5.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|---|---|---|---|
| Variable | TS1 | TS2 | TT1 | TT2 | | | | |
| Type | F | F | F | F | | | | |

Discrete Beam Card (type 6). Card 2 for ELFORM equal to 6 for any material *other* than material type 146.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|------|-----|----|--------|-------|-------|-------|
| Variable | VOL | INER | CID | CA | OFFSET | RRCON | SRCON | TRCON |
| Type | F | F | F | F | F | F | F | F |

Discrete Beam Card (type 6, mat 146). Card 2 for ELFORM equal to 6 for material type 146.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|------|-----|-------|-------|---|---|---|
| Variable | VOL | INER | CID | DOFN1 | DOFN2 | | | |
| Type | F | F | F | F | F | | | |

2D Shell Card (types 7 and 8). Card 2 for ELFORM equal to 7 or 8.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|---|---|---|---|
| Variable | TS1 | TS2 | TT1 | TT2 | | | | |
| Type | F | F | F | F | | | | |

Spot Weld Card (type 9). Card 2 for ELFORM equal to 9.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-------|---|-------|---|
| Variable | TS1 | TS2 | TT1 | TT2 | PRINT | | ITOFF | |
| Type | F | F | F | F | F | | F | |

Integrated Beam Card (types 14). Card 2 for ELFORM equal to 14.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|-------|--------|---|---|---|---|---|
| Variable | PR | IOVPR | IPRSTR | | | | | |
| Type | F | F | F | F | | | | |

VARIABLE**DESCRIPTION**

SECID

Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.

ELFORM

Element formulation options:

EQ.1: Hughes-Liu with cross section integration (default),

EQ.2: Belytschko-Schwer resultant beam (resultant),

EQ.3: truss (resultant). See [Remark 2](#).

EQ.4: Belytschko-Schwer full cross-section integration,

EQ.5: Belytschko-Schwer tubular beam with cross-section integration,

EQ.6: discrete beam/cable,

EQ.7: 2D plane strain shell element (xy plane),

EQ.8: 2D axisymmetric volume weighted shell element (xy plane, y -axis of symmetry),

EQ.9: spotweld beam, see *MAT_SPOTWELD.

EQ.11: integrated warped beam. See [Remark 4](#)

EQ.12: resultant warped beam

EQ.13: small displacement, linear Timoshenko beam with exact stiffness. See [Remark 6](#)

EQ.14: Elbow integrated tubular beam element. An user

| VARIABLE | DESCRIPTION |
|----------|---|
| | defined integration rule with tubular cross section (9) must be used. |
| | Note that the 2D and 3D element types must not be mixed, and different types of 2D elements must not be used together. For example, the plane strain element type must not be used with the axisymmetric element type. In 3D the different beam elements types, i.e., 1-6 and 9 can be freely mixed together. |
| SHRF | Shear factor. This factor is not needed for truss, resultant beam, discrete beam, and cable elements. The recommended value for rectangular sections is 5/6, the default is 1.0. |
| QR/IRID | Quadrature rule or rule number for user defined rule for integrated beams. See Remark 10 regarding beam formulations 7 and 8. |
| | <p>EQ.1.0: one integration point,</p> <p>EQ.2.0: 2 × 2 Gauss quadrature (default beam),</p> <p>EQ.3.0: 3 × 3 Gauss quadrature,</p> <p>EQ.4.0: 3 × 3 Lobatto quadrature,</p> <p>EQ.5.0: 4 × 4 Gauss quadrature</p> <p>EQ.-n: where n is the number of the user defined rule. IRID integration rule n is defined using *INTEGRATION_BEAM card.</p> |
| CST | <p>Cross section type, not needed for truss, resultant beam, discrete beam, and cable elements:</p> <p>EQ.0.0: rectangular,</p> <p>EQ.1.0: tubular (circular only),</p> <p>EQ.2.0: arbitrary (user defined integration rule).</p> |
| SCOOR | <p>Affects the discrete beam formulation (see Remark 7) and also the update of the local coordinate system of the discrete beam element. This parameter does not apply to cable elements. The force and moment resultants in the output databases are output in the local coordinate system. See Remark 9 for more on the local coordinate system update.</p> <p>EQ.-13.0: Like -3.0, but with correction for beam rotation</p> |

| VARIABLE | DESCRIPTION |
|-----------|---|
| EQ.-12.0: | Like -2.0, but with correction for beam rotation |
| EQ.-3.0: | beam node 1, the angular velocity of node 1 rotates triad, |
| EQ.-2.0: | beam node 1, the angular velocity of node 1 rotates triad but the r-axis is adjusted to lie along the line between the two beam nodal points. This option is not recommended for zero length discrete beams., |
| EQ.-1.0: | beam node 1, the angular velocity of node 1 rotates triad, |
| EQ.0.0: | centered between beam nodes 1 and 2, the average angular velocity of nodes 1 and 2 is used to rotate the triad, |
| EQ.+1.0: | beam node 2, the angular velocity of node 2 rotates triad. |
| EQ.+2.0: | beam node 2, the angular velocity of node 2 rotates triad. But the r-axis is adjusted to lie along the line between the two beam nodal points. This option is not recommended for zero length discrete beams. |
| EQ.+3.0: | beam node 2, the angular velocity of node 2 rotates triad. |
| EQ.+12.0: | Like +2.0, but with correction for beam rotation |
| EQ.+13.0: | Like +3.0, but with correction for beam rotation |
| NSM | Nonstructural mass per unit length. This option applies to beam types 1-5 and does not apply to discrete, 2D, and spotweld beams, respectively. |
| TS1 | Beam thickness (CST = 0.0, 2.0) or outer diameter (CST = 1.0) in s direction at node n_1 . Note that the thickness defined on the *ELEMENT_BEAM_THICKNESS card overrides the definition give here. Thickness at node n_1 for beam formulations 7 and 8. |
| TS2 | Beam thickness (CST = 0.0, 2.0) or outer diameter (CST = 1.0) in s direction at node n_2 . For truss elements only, it is the ramp up time for the stress initialization by dynamic relaxation. Thickness at node n_2 for beam formulations 7 and 8. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| TT1 | Beam thickness (CST = 0.0, 2.0) or inner diameter (CST = 1.0) in t direction at node n_1 . For truss elements only, it is the stress for the initialization of the stress by dynamic relaxation. Not used by beam formulations 7 and 8. |
| TT2 | Beam thickness (CST = 0.0, 2.0) or inner diameter (CST = 1.0) in t direction at node n_2 . Not used by beam formulations 7 and 8. |
| NSLOC | Location of reference surface normal to s axis for Hughes-Liu beam elements only. See Remark 5 . EQ.1.0: side at $s = 1.0$, EQ.0.0: center, EQ.-1.0: side at $s = -1.0$. |
| NTLOC | Location of reference surface normal to t axis for Hughes-Liu beam elements only. See Remark 5 . EQ.1.0: side at $t = 1.0$, EQ.0.0: center, EQ.-1.0: side at $t = -1.0$. |
| A | Cross-sectional area. The definition on *ELEMENT_BEAM_THICKNESS overrides the value defined here. |
| ISS | I_{ss} , area moment of inertia about local s -axis. The definition on *ELEMENT_BEAM_THICKNESS overrides the value defined here. |
| ITT | I_{tt} , area moment of inertia about local t -axis. The definition on *ELEMENT_BEAM_THICKNESS overrides the value defined here. |
| J | J , torsional constant. The definition on *ELEMENT_BEAM_THICKNESS overrides the value defined here. If J is zero, then J is reset to the sum of $ISS + ITT$ as an approximation for warped beam. |
| SA | Shear area. The definition on *ELEMENT_BEAM_THICKNESS overrides the value defined here. |

| VARIABLE | DESCRIPTION |
|----------|---|
| IST | I_{st} , product area moment of inertia w.r.t. local s - and t -axis. This is only non-zero for asymmetric cross sections and it can take positive and negative values, e.g. it is negative for SECTION_03. |
| ITORM | Flag for improved representation of torsional modes which can be activated only if an eigenvalue analysis is performed. Applies only to beam type 13. <p>EQ.0.0: Not active. The torsional inertia from structural analysis is used. This may result in too large eigenvalues related to torsional modes.</p> <p>EQ.1.0: The mass related to the torsional mode is recomputed more accurately.</p> |
| YS | s coordinate of shear center of cross-section. (The coordinate system is located at the centroid.) |
| ZS | t coordinate of shear center of cross-section. (The coordinate system is located at the centroid.) |
| IYR | $\int_A sr^2 dA$, where $r^2 = s^2 + t^2$ |
| IZR | $\int_A tr^2 dA$, where $r^2 = s^2 + t^2$ |
| IRR | $\int_A r^4 dA$, where $r^2 = s^2 + t^2$ |
| IW | Warping constant. $\int_A \omega^2 dA$, where ω is the sectorial area. |
| IWR | $\int_A \omega r^2 dA$ |
| PR | Pressure inside ELBOW elements that belong to the section. The pressure acts as a stiffener and will reduce the ovalization of the pipe. Pressure acting on the inside wall is taken as positive. |
| IOVPR | Print flag for the ELBOW ovalization degrees of freedom. <p>EQ.1.0: an ascii file named <code>elbwov</code> is created and filled with the ovalization. Default no file is created.</p> |
| IPRSTR | Flag for adding stress due to pressure PR into the material routine. <p>EQ.0: No stress is added to the material. In this case the pressure only acts as a stiffener for the tube.</p> <p>EQ.1: The pressure PR is used to calculate additional axial and</p> |

| VARIABLE | DESCRIPTION | | | | | | | | | | | | | | | | | | | | | | |
|----------------------------|--|------------------------|----------------------|------------------------|------------------------|------------------------|--------------------------|------------------------|--------------------------|----------------------------|--------------------------|------------------------|--------------------------|----------------------------|--------------------------|-------------------------|----------------------------|------------------------|------------------------|--------------------------|--------------------------|--------------------------|----------------------------|
| | <p>circumferential stresses due to the applied pressure PR. The stress added is given by:</p> $\sigma_{\text{axial}} = PR \times \frac{D}{4T}, \quad \sigma_{\text{circ}} = pr \times \frac{D}{2T}$ <p>for a straight pipe, and</p> $\sigma_{\text{axial}} = PR \times \frac{D}{4T}, \quad \sigma_{\text{circ}} = PR \times \frac{D}{4T} \frac{[2R + r \cos(\theta)]}{[R + r \cos(\theta)]}$ <p>for a curved pipe. D is the pipe diameter, T is the thickness, R is the curvature of the bend, r is the pipe radius (mean) and θ is an angle pointing out a point on the pipe. EQ.1 also includes the stiffening effect.</p> | | | | | | | | | | | | | | | | | | | | | | |
| RAMPT | Optional ramp-up time for dynamic relaxation. At the end of the ramp-up time, a uniform stress, STRESS, will exist in the truss in the truss element. This option will not work for hyperelastic materials. | | | | | | | | | | | | | | | | | | | | | | |
| STRESS | Optional initial stress for dynamic relaxation. At the end of dynamic relaxation a uniform stress equal to this value should exist in the truss element. | | | | | | | | | | | | | | | | | | | | | | |
| STYPE | <p>Section type (A format) of resultant beam, see Figure 37-1:</p> <table style="width: 100%; border: none;"> <tr> <td style="width: 50%;">EQ.SECTION_01: I-Shape</td> <td style="width: 50%;">EQ.SECTION_12: Cross</td> </tr> <tr> <td>EQ.SECTION_02: Channel</td> <td>EQ.SECTION_13: H-Shape</td> </tr> <tr> <td>EQ.SECTION_03: L-shape</td> <td>EQ.SECTION_14: T-Shape 2</td> </tr> <tr> <td>EQ.SECTION_04: T-shape</td> <td>EQ.SECTION_15: I-Shape 3</td> </tr> <tr> <td>EQ.SECTION_05: Tubular box</td> <td>EQ.SECTION_16: Channel 2</td> </tr> <tr> <td>EQ.SECTION_06: Z-Shape</td> <td>EQ.SECTION_17: Channel 3</td> </tr> <tr> <td>EQ.SECTION_07: Trapezoidal</td> <td>EQ.SECTION_18: T-Shape 3</td> </tr> <tr> <td>EQ.SECTION_08: Circular</td> <td>EQ.SECTION_19: Box-Shape 2</td> </tr> <tr> <td>EQ.SECTION_09: Tubular</td> <td>EQ.SECTION_20: Hexagon</td> </tr> <tr> <td>EQ.SECTION_10: I-Shape 2</td> <td>EQ.SECTION_21: Hat-Shape</td> </tr> <tr> <td>EQ.SECTION_11: Solid Box</td> <td>EQ.SECTION_22: Hat-Shape 2</td> </tr> </table> | EQ.SECTION_01: I-Shape | EQ.SECTION_12: Cross | EQ.SECTION_02: Channel | EQ.SECTION_13: H-Shape | EQ.SECTION_03: L-shape | EQ.SECTION_14: T-Shape 2 | EQ.SECTION_04: T-shape | EQ.SECTION_15: I-Shape 3 | EQ.SECTION_05: Tubular box | EQ.SECTION_16: Channel 2 | EQ.SECTION_06: Z-Shape | EQ.SECTION_17: Channel 3 | EQ.SECTION_07: Trapezoidal | EQ.SECTION_18: T-Shape 3 | EQ.SECTION_08: Circular | EQ.SECTION_19: Box-Shape 2 | EQ.SECTION_09: Tubular | EQ.SECTION_20: Hexagon | EQ.SECTION_10: I-Shape 2 | EQ.SECTION_21: Hat-Shape | EQ.SECTION_11: Solid Box | EQ.SECTION_22: Hat-Shape 2 |

| D1-D6 | Input parameters for section option using STYPE above. | | | | | | | | | | | | | | | | | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| VOL | Volume of discrete beam and scalar (MAT_146) beam. Used in calculating mass. If VOL = 0 for cable elements, volume is calculated as the product of cable length and cable area. If the mass density of the material model for the discrete beam is set to unity, the magnitude of the lumped mass can be defined here instead. This lumped mass is partitioned to the two nodes of the beam element. The translational time step size for the type 6 beam is dependent on the volume, mass density, and the translational stiffness values, so it is important to define this parameter. Defining the volume is also essential for mass scaling if the type 6 beam controls the time step size. |
| INER | Mass moment of inertia for the six degree of freedom discrete beam and scalar (MAT_146) beam. This parameter does not apply to cable elements. This lumped inertia is partitioned to the two nodes of the beam element. The rotational time step size for the type 6 beam is dependent on the lumped inertia and the rotational stiffness values, so it is important to define this parameter if the rotational springs are active. Defining the rotational inertia is also essential for mass scaling if the type 6 beam rotational stiffness controls the time step size. It is recommended to always set this parameter to a reasonable nonzero value to avoid instabilities and/or having model dependent rotational inertia properties, if the value set is smaller than that of an equivalent solid sphere LS-DYNA will issue a warning. |
| CID | Coordinate system ID for orientation (material types 66-69, 93, 95, 97), see *DEFINE_COORDINATE_option. If CID = 0, a default coordinate system is defined in the global system or on the third node of the beam, which is used for orientation. This option is not defined for material types than act between two nodal points, such as cable elements. The coordinate system rotates with the discrete beam, see SCOR above. |
| CA | Cable area. See material type 71, *MAT_CABLE_DISCRETE_BEAM. |
| OFFSET | Optional offset for cable. See material type 71, *MAT_CABLE_DISCRETE_BEAM. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| RRCON | <i>r</i> -rotational constraint for local coordinate system (see Remark 8) EQ.0.0: Coordinate ID rotates about <i>r</i> axis with nodes. EQ.1.0: Rotation is constrained about the <i>r</i> -axis |
| SRCON | <i>s</i> -rotational constraint for local coordinate system (see Remark 8) EQ.0.0: Coordinate ID rotates about <i>s</i> axis with nodes. EQ.1.0: Rotation is constrained about the <i>s</i> -axis |
| TRCON | <i>t</i> -rotational constraint for local coordinate system (see Remark 8) EQ.0.0: Coordinate ID rotates about <i>t</i> axis with nodes. EQ.1.0: Rotation is constrained about the <i>t</i> -axis |
| CID | Coordinate system ID for orientation, material type 146, see *DEFINE_COORDINATE_SYSTEM. If CID = 0, a default coordinate system is defined in the global system. |
| DOFN1 | Active degree-of-freedom at node 1, a number between 1 and 6 where 1 is <i>x</i> -translation and 4 is <i>x</i> -rotation. |
| DOFN2 | Active degree-of-freedom at node 2, a number between 1 and 6. |
| PRINT | Output spot force resultant from spotwelds. EQ.0.0: Data is output to swforc file. EQ.1.0: Output is suppressed. |
| ITOFF | Option to specify torsional behavior for spotweld beams. EQ.0.0: Torsional stiffness is active. EQ.1.0: Torsional stiffness is zero (free to twist). |

Remarks:

1. **Implicit Time Integrator.** For implicit calculations all of the beam element choices are implemented:
2. **Truss Elements.** For the truss element, define the cross-sectional area, *A*, only.
3. **Local Coordinate System Rotation.** The local coordinate system rotates as the nodal points that define the beam rotate. In some cases this may lead to

unexpected results if the nodes undergo significant rotational motions. In the definition of the local coordinate system using `*DEFINE_COORDINATE_NODES`, if the option to update the system each cycle is active then this updated system is used. This latter technique seems to be more stable in some applications.

- 4. **Integrated Warped Beam.** The integrated warped beam (type 11) is a 7 degree of freedom beam that must be used with an integration rule of the open standard cross sections, see `*INTEGRATION_BEAM`. To incorporate the additional degrees of freedom corresponding to the twist rates, the user should declare one scalar node (`*NODE_SCALAR`) for each node attached to a warped beam. This degree of freedom is associated to the beam element using the warpage option on the `*ELEMENT_BEAM` card.
- 5. **Beam Offsets.** Beam offsets are sometimes necessary for correctly modeling beams that act compositely with other elements such as shells or other beams. A beam offset extends from the beam's n_1 -to- n_2 axis to the reference axis of the beam. The beam reference axis lies at the origin of the local s and t axes. This origin is located at the center of the cross-section footprint for beam formulations 1 and 11 but it is located at the cross-section centroid for beam formulation 2. Note that for cross-sections that are not doubly symmetric, e.g, a T-section, the center of the cross-section footprint and the centroid of the cross-section do not coincide. The offset in the positive s -direction is

$$\begin{aligned} \text{s-offset} &= -0.5 \times \text{NSLOC} \\ &\quad \times (\text{beam cross-section dimension in } s\text{-direction}). \end{aligned}$$

Similarly, the offset in the positive t -direction is

$$\begin{aligned} \text{t-offset} &= -0.5 \times \text{NTLOC} \\ &\quad \times (\text{beam cross-section dimension in } t\text{-direction}). \end{aligned}$$

If IRID is used to point to an integration rule with $\text{ICST} > 0$, then offsets must be defined using SREF and TREF on the `*INTEGRATION_BEAM` card as they will override NSLOC and NTLOC even if $\text{SREF} = 0$ or $\text{TREF} = 0$. See also `*ELEMENT_BEAM_OFFSET` for an alternate approach to defining beam offsets.

- 6. **3-D Timoshenko Beam.** Element type 13 is a 3-D Timoshenko resultant-based beam element with two nodes for small displacement, linear isotropic elasticity. The stiffness matrix is identical to the residual stiffness formulation used in the Belytschko-Schwer element (type 2). This element only works with `*MAT_ELASTIC`. It uses the reference geometry to calculate the element stiffness and calculates the element forces by multiplying the element stiffness by the displacements. Offsets work but they are fixed for all time like the reference geometry.

7. **SCOOR.** If the magnitude of SCOOR is less than or equal to unity then zero length discrete beams are assumed with infinitesimal separation between the nodes in the deformed state. For large separations or nonzero length beams set |SCOOR| to 2, 3, 12, or 13, in which case true beam-like behavior is invoked to provide equilibrating torques to offset any force couples that arise due to translational stiffness or translational damping. Also, rigid body rotation is measured and the spring strain modified so that rotation does not create strain. A flaw in this strain modification was found in the implementation of |SCOOR| = 2 and 3 the improved formulation is activated by setting |SCOOR| = 12 and 13. The original options were left in place to allow legacy data to run without change.
8. **Disabling Nodal Rotations.** RRCON, SRCON, and TRCON are optional and apply only to non-cable discrete beams. If set to 1, RRCON, SRCON, and TRCON will prevent nodal *rotations* about the local *r*, *s*, *t* axes, respectively, from affecting the update of the local coordinate system. These three parameters have no influence on how nodal translations may affect the local coordinate system update.
9. **Note about Local Coordinate Updates and FLAG.** If CID is nonzero for a discrete beam and the coordinate system identified by CID uses *DEFINE_COORDINATE_NODES with FLAG=1, the beam local system is updated based on the current orientation of the three nodes identified in *DEFINE_COORDINATE_NODES. In this case, local coordinate system updates per SCOOR types 0, ± 1 , ± 3 , and ± 13 are inactive while for SCOOR types ± 2 and ± 12 , a final adjustment is made to the local coordinate system so that the local *r*-axis lies along the n_1 -to- n_2 axis of the beam. An optional output database (*DATABASE_DISBOU) will report relative displacements, rotations, and force resultants of discrete beams, all in the local coordinate system.
10. **Beam Forms 7 and 8.** Beam formulations 7 and 8 are 2D shell elements. For these two formulations, variable QR/IRID is the number of through thickness integration points for the shell. Output for these integration points is controlled by the variable BEAMIP in *DATABASE_EXTENT_BINARY.
11. **Beam Form 1.** The integration points for beam formulation 1 are located at mid-length and are arranged in the cross-section according to the specified integration rule. Stresses are reported at integration points according to the variable BEAMIP in *DATABASE_EXTENT_BINARY.

***SECTION_BEAM_AISC**

Purpose: Define cross-sectional properties for beams and trusses using section labels from the AISC Steel Construction Manual, 2005, 13th Edition, as published in the AISC Shapes Database V13.1.1

Card Summary:

Card Sets. For each BEAM_AISC section include one pair of Cards 1 and 2. This input ends at the next keyword ("*") card.

Card 1. This card is required.

| | |

VARIABLE

DESCRIPTION

- ELFORM Element formulation (see *SECTION_BEAM). Only types 1-5,11,12 are allowed
- SHRF Shear factor (see *SECTION_BEAM)
- NSM Non-structural mass per unit length

| VARIABLE | DESCRIPTION |
|-----------------|---|
| LFAC | GT.0.0: Length scale factor to convert dimensions from standard units If LFAC < 0, then a predefined length factor for specific model units is used: EQ.-1.0: ft EQ.-2.0: m EQ.-3.0: in EQ.-4.0: mm EQ.-5.0: cm |
| NSLOC | Location of reference surface (see *SECTION_BEAM) |
| NTLOC | Location of reference surface (see *SECTION_BEAM) |
| K | Integration refinement parameter (see *INTEGRATION_BEAM) |
| RAMPT | Optional ramp-up time (see *SECTION_BEAM) |
| STRESS | Optional initial stress (see *SECTION_BEAM) |

Remarks:

This keyword uses the dimensions of the standard AISC beams sections — as defined by the section label — to define *SECTION_BEAM and *INTEGRATION_BEAM cards with the appropriate parameters.

The AISC section label may be specified either as the shape designation as seen in the AISC Steel Construction Manual, 2005, or the designation according to the AISC Naming Convention for Structural Steel Products for Use in Electronic Data Interchange (EDI), 2001. As per the EDI convention, the section labels are to be case-sensitive and space sensitive, i.e. “W36X150” is acceptable but “W36 x 150” is not. Labels can be specified in terms of either the U.S. Customary units (in) or metric units (mm), which will determine the length units for the section dimensions. The parameter LFAC may be used as a multiplier to convert the dimensions to other lengths units. For user convenience, predefined conversion factors are provided for specific choices of the model length unit.

AISC requires the following legal notice specifying that LS-DYNA users may not extract AISC shapes data in any manner from LS-DYNA to create commercial software. Users

are certainly allowed to create LS-DYNA input models for commercial purposes using this card.

You agree that you will use AISC Data for non-commercial use only, meaning that it will not be used to develop or create revenue-producing software. You agree not to assign, copy, transfer or transmit the AISC Shapes Database or any AISC Data to any third party.

YOU AGREE NOT TO USE OR EXPLOIT AISC DATA OR THE AISC SHAPES DATABASE EXCEPT AS EXPRESSLY PERMITTED HEREIN.

***SECTION_DISCRETE**

Purpose: Defined spring and damper elements for translation and rotation. These definitions must correspond with the material type selection for the elements, that is, *MAT_SPRING_... and *MAT_DAMPER_...

Card Sets. For each DISCRETE section include a pair of Cards 1 and 2. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-----|----|----|----|----|---|---|
| Variable | SECID | DRO | KD | V0 | CL | FD | | |
| Type | I/A | I | F | F | F | F | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|---|---|---|---|---|---|
| Variable | CDL | TDL | | | | | | |
| Type | F | F | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|-------|---|
| SECID | Section ID. SECID is referenced on the *PART card. A unique number or label must be specified. |
| DRO | Displacement/Rotation Option: EQ.0: the material describes a translational spring/damper, EQ.1: the material describes a torsional spring/damper. |
| KD | Dynamic magnification factor, k_d . See Remarks 1 and 2 below. |
| V0 | Test velocity, V_0 . See Remarks 1 and 2 below. |
| CL | Clearance. See Remark 3 below. |
| FD | Failure deflection (twist for DRO = 1). Negative for compression, positive for tension. |
| CDL | Deflection (twist for DRO = 1) limit in compression. See Remark 4 below. |

| VARIABLE | DESCRIPTION |
|----------|--|
| TDL | Deflection (twist for DRO = 1) limit in tension. See Remark 4 below. |

Remarks:

1. **Optional Constants.** The constants from KD to TDL are optional and do not need to be defined.
2. **Forces and Amplification Factors.** If k_d is nonzero, the forces computed from the spring elements are assumed to be the static values and are scaled by an amplification factor to obtain the dynamic value:

$$F_{\text{dynamic}} = \left(1. + k_d \frac{V}{V_0} \right) F_{\text{static}} ,$$

where

V = absolute value of the relative velocity between the nodes.

V_0 = dynamic test velocity.

For example, if it is known that a component shows a dynamic crush force at 15 m/s equal to 2.5 times the static crush force, use $k_d = 1.5$ and $V_0 = 15$.

3. **Clearance.** Here, “clearance” defines a compressive displacement which the spring sustains before beginning the force-displacement relation given by the load curve defined in the material selection. If a non-zero clearance is defined, the spring is compressive only.
4. **Deflection Limits.** The deflection limit in compression and tension is restricted in its application to no more than one spring per node subject to this limit and to deformable bodies only. For example, in the former case, if three springs are in series, either the center spring or the two end springs may be subject to a limit, but not all three. When the limiting deflection is reached, momentum conservation calculations are performed, and a common acceleration is computed in the appropriate direction. An error termination will occur if a rigid body node is used in a spring definition where deflection is limited.

Constrained boundary conditions on the *NODE cards and the BOUNDARY_-SPC cards must not be used for nodes of springs with deflection limits.

5. **Implicit.** Discrete elements can be included in implicit applications.

*SECTION_POINT_SOURCE

Purpose: This command provides the inlet boundary condition for single gas in flow (inflation potential) using a set of point source(s). It also provides the inflator orifice geometry information. It requires 3 curves defining the inlet condition for the inflator gas coming into the tank or an airbag as input ($\bar{T}_{\text{gas corrected}}(t)$, $v_r(t)$, and $\text{vel}(t)$). Please see also the *ALE_TANK_TEST card for additional information.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|--------|---------|--------|--------|--------|---|
| Variable | SECID | LCIDT | LCIDVR | LCIDVEL | NIDLC1 | NIDLC2 | NIDLC3 | |
| Type | I/A | I | I | I | I | I | I | |
| Default | 0 | 0 | 0 | 0 | 0 | 0 | 0 | |

Source Node Cards. Include one card for each source node. This input ends at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|-------|-------|---|---|---|---|---|
| Variable | NODEID | VECID | ORIFA | | | | | |
| Type | I | I | F | | | | | |
| Default | 0 | 0 | 0.0 | | | | | |

VARIABLE**DESCRIPTION**

| | |
|---------|--|
| SECID | Section ID. A unique number or label must be specified. |
| LCIDT | Temperature load curve ID |
| LCIDVR | Relative volume load curve ID |
| LCIDVEL | Inlet flow velocity load curve ID |
| NIDLC1 | The 1 st node ID defining a local coordinate (See Remark 2). |
| NIDLC2 | The 2 nd node ID defining a local coordinate (See Remark 2). |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| NIDLC3 | The 3 rd node ID defining a local coordinate (See Remark 2). |
| NODEID | The node ID(s) defining the point source(s). |
| VECID | The vector ID defining the direction of flow at each point source. |
| ORIFA | The orifice area at each point source. |

Remarks:

1. **Airbag Inflator Tank Test.** In an airbag inflator tank test, the tank pressure data is measured. This pressure is used to derive $\dot{m}(t)$ and the estimated $\bar{T}_{\text{gas}}(t)$, usually using a lumped-parameter method, a system of conservation equations and EOS. Subsequently $\dot{m}(t)$ and $\bar{T}_{\text{gas}}(t)$ (stagnation temperature) are used as input to obtain $\bar{T}_{\text{gas_corrected}}(t)$ (static temperature), $v_r(t)$, and $\text{vel}(t)$. These 3 curves are then used to describe inflator gas inlet condition (see *ALE_TANK_TEST for more information).
2. **Local Coordinate System.** In a car crash model, the inflator housing may get displaced during the impact. The 3 node IDs defines the local reference coordinate system to which the point sources are attached. These 3 reference nodes may be located on a rigid body which can translate and rotate as the inflator moves during the impact. This allows for the point sources to move in time. These reference nodes may be used as the point sources themselves.
3. **ALE Tank Test Keyword.** If the *ALE_TANK_TEST card is present, please see the Remarks under that card.

Example:

Consider a tank test model which consists of the inflator gas (PID 1) and the air inside the tank (PID 2). The 3 load curves define the thermodynamic and kinetic condition of the incoming gas. The nodes define the center of the orifice, and the vector the direction of flow at each orifice.

*SECTION

*SECTION_POINT_SOURCE_MIXTURE

*SECTION_POINT_SOURCE_MIXTURE

Purpose: This command provides (a) an element formulation for a solid ALE part of the type similar to ELFORM = 11 of *SECTION_SOLID, and (b) the inlet gas injection boundary condition for multiple-gas mixture in-flow using a set of point source(s). It also provides the inflator orifice geometry information. This must be used in combination with the *MAT_GAS_MIXTURE and/or *INITIAL_GAS_MIXTURE card (see [Remark 1](#)).

VARIABLE

DESCRIPTION

SECID

Section ID. A unique number or label must be specified.

| VARIABLE | DESCRIPTION |
|----------|--|
| LCIDT | Inflator gas mixture average stagnation temperature load curve ID (all gases of the mixture are assumed to have the same average temperature). |
| LCIDVEL | User-defined inflator gas mixture average velocity load curve ID. If LCIDVEL = 0 or blank, LSDYNA will estimate the inlet gas velocity. |
| NIDLC001 | The 1 st node ID defining a local coordinate (see Remark 2). |
| NIDLC002 | The 2 nd node ID defining a local coordinate (see Remark 2). |
| NIDLC003 | The 3 rd node ID defining a local coordinate (see Remark 2). |
| IDIR | A flag for constraining the nodal velocity of the nodes of the ALE element containing a point source. EQ.0: ALE nodes behind the point source (relative position of nodes based on the vector direction of flow of point source) will have zero velocity (default). EQ.1: all ALE nodes will have velocity distributed based on energy conservation. This option seems to be more robust in airbag modeling (see Remark 5). |
| LCMD n | The mass flow rate load curve ID of the n^{th} gas in the mixture. See Remark 3 . |
| NODEID | The node ID(s) defining the point sources (see Remark 7). |
| VECID | The vector ID defining the direction of flow at each point source. |
| ORIFA | The orifice area at each point source. |

Remarks:

1. **Keyword Applications.** This command is used to define a part that acts as the ideal gas mixture injection source. The associated ALE material (gas mixture) may not be present at time zero but can be introduced (injected) into an existing ALE domain. For airbag applications, the input from control volume analysis, inlet mass flow rate, $\dot{m}(t)$, and, inlet stagnation gas temperature, $\bar{T}_{\text{gas}}(t)$ may be used as direct input for ALE analysis. If available, the user may input a load curve for the gas mixture average inlet velocity. If not, LS-DYNA will estimate the inlet gas velocity.

2. **Local Coordinate System.** In a car crash model, the inflator housing may get displaced during the impact. The 3 node IDs defines the local reference coordinate system to which the point sources are attached. These 3 reference nodes may be located on a rigid body which can translate and rotate as the inflator moves during the impact. This allows for the point sources to move in time. These reference nodes may be used as the point sources themselves.
3. **Mass Flow Rate.** The gas mixture is assumed to have a uniform temperature ($\bar{T} \approx T_i$) and inlet velocity. However, the species in the mixture may each have a different inlet mass flow rate.
4. **Model.** A brief review of the concept used is presented. The total energy, e_t , is the sum of internal (e_i) and kinetic ($V^2/2$) energies (per unit mass).

$$e_T = e_i + \frac{V^2}{2}$$

$$C_V T_{stag} = C_V T + \frac{V^2}{2}$$

$$T_{stag} = T + \frac{V^2}{2C_V}$$

The distinction between stagnation and static temperatures is shown above. C_V is the constant-volume heat capacity. The gas mixture average internal energy per unit mass in terms of mixture species contribution is

$$e_i = \bar{C}_V \bar{T} = \sum_i \left(\frac{\rho_i}{\rho_{mixture}} \right) C_{V_i} T_i = \left[\sum_i \left(\frac{\rho_i}{\rho_{mixture}} \right) C_{V_i} \right] \bar{T}$$

$$\bar{C}_V = \left[\sum_i \left(\frac{\rho_i}{\rho_{mixture}} \right) C_{V_i} \right]$$

Since we approximate $\bar{T} \approx T_i$, then gas mixture average static temperature is related to the mixture average internal energy per unit mass as following

$$\bar{T} = \frac{e_i}{\left[\sum_i \left(\frac{\rho_i}{\rho_{mixture}} \right) C_{V_i} \right]}$$

Note that the “i” subscript under “e” denotes “internal” energy, while the other “i” subscripts denote the “ith” species in the gas mixture. The total mixture pressure is the sum of the partial pressures of the individual species.

$$\bar{p} = \sum_i p_i$$

The ideal gas EOS applies to each individual species (by default)

$$P_i = \rho_i (C_{P_i} - C_{V_i}) T_i$$

5. **Energy Conservation.** Generally, conservation of both momentum and kinetic (KE) at the same time is impossible. Typically, internal energy (IE) is conserved and KE may not be. This may result in some KE loss (hence, total

energy loss). For many analyses this is tolerable, but for an airbag, a reduction of the inflating potential of the inflator gas may result.

In `*MAT_GAS_MIXTURE` computation, any kinetic energy not accounted for during advection is stored in the internal energy. Therefore, no kinetic energy is lost, and the total energy of the element is conserved over the advection step. This simple, ad hoc approach is not rigorously derived for the whole system based on first principles. Therefore, it is not guaranteed to apply universally to all scenarios. The user must validate the model with data.

6. **EOS.** Since ideal gas is assumed, there is no need to define the EOS for the gases in the mixture.
7. **Point Source Location.** In general, it is best to locate a point source near the center of an ALE element. Associated with each point source is an area and a vector indicating flow direction. Each point source should occupy one ALE element by itself, and there should be at least two empty ALE elements between any two point sources. A point source should be located at least three elements away from the free surface of an ALE mesh for stability.

Example 1:

Consider a tank test model without coupling which consists of:

- a background mesh with air (PID 1 = gas 1) initially inside that mesh (tank space), and
- the inflator gas mixture (PID 2 consisting of inflator gases 2, 3, and 4).

The mixture is represented by one AMMGID and the air by another AMMGID.

The tank internal space is simply modeled with an Eulerian mesh of the same volume. The tank itself is not modeled thus no coupling is required. The inflator gases fill up this space mixing with the air initially inside the tank.

The background air (gas 1) is included in the gas mixture definition in this case because that air will participate in the mixing process. Only include in the mixture those gases that actually undergo mixing (gases 1, 2, 3 and 4). Note that for an airbag model, the "outside" air should not be included in the mixture (it should be defined independently) since it does not participate in the mixing inside the airbag. This is shown in the next example.

The nodes define the center of the orifices, and the vectors define the directions of flow at these orifices.

Example 2:

Consider an airbag inflation model which consists of:

- a background Eulerian mesh for air initially outside the airbag (PID 1)
- the inflator gas mixture (PID 2 consisting of inflator gases 1, 2, and 3).

The mixture is represented by one AMMGID and the air by another AMMGID.

The background air (PID 1) is NOT included in the gas mixture definition in this case because that air will NOT participate in the mixing process. Only include in the mixture those gases that actually undergo mixing (gases 1, 2, and 3). Gases 1, 2, and 3 in this example correspond to gases 2, 3, and 4 in example 1. Compare the air

properties in PID 1 here to that of example 1. Note that the *INITIAL_GAS_MIXTURE card is not required to initialize the background mesh in this case.

***SECTION_SEATBELT**

Purpose: Define section properties for the seat belt elements. This card is required for the *PART Section. Currently, only the ID is required.

Seatbelt Section Cards. Include one card for each SEATBELT section. This input ends at the next keyword (“*”) card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|------|-------|---|---|---|---|---|
| Variable | SECID | AREA | THICK | | | | | |
| Type | I/A | F | F | | | | | |
| Default | none | 0.01 | ↓ | | | | | |

VARIABLE**DESCRIPTION**

| | |
|-------|--|
| SECID | Section ID. A unique number or label must be specified. |
| AREA | Optional area of cross-section used in the calculation of contact stiffness, which is proportional to the cross-section area. |
| THICK | Optional contact thickness which can be overwritten by a nonzero SST defined in *CONTACT. If not defined, a value proportional to element length is used as the contact thickness. |

Remarks:

Seatbelt elements are implemented for both explicit and implicit calculations.

*SECTION

*SECTION_SHELL

*SECTION_SHELL_{OPTION}

Available options include:

<BLANK>

EFG

THERMAL

XFEM

Purpose: Define section properties for shell elements.

Card Sets. For each shell section, of a type matching the keyword's options, include one set data cards. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

EQ.9: Fully integrated Belytschko-Tsay membrane

EQ.10: Belytschko-Wong-Chiang

EQ.11: Fast (co-rotational) Hughes-Liu

EQ.12: Plane stress (x - y plane)EQ.13: Plane strain (x - y plane)EQ.14: Axisymmetric solid (x - y plane, y -axis of symmetry) - area weighted (see [Remark 10](#))EQ.15: Axisymmetric solid (x - y plane, y -axis of symmetry) -

| VARIABLE | DESCRIPTION |
|-----------------|--|
| | volume weighted |
| EQ.16: | Fully integrated shell element (very fast) |
| EQ.-16: | Fully integrated shell element modified for higher accuracy. See Remark 13 . |
| EQ.17: | Fully integrated DKT, triangular shell element. See Remark 9 . |
| EQ.18: | Fully integrated linear DK quadrilateral/triangular shell |
| EQ.20: | Fully integrated linear assumed strain C0 shell. See Remark 2 . |
| EQ.21: | Fully integrated linear assumed strain C0 shell (5 DOF) |
| EQ.22: | Linear shear panel element. 3 DOF per node. (See Remark 3) |
| EQ.23: | 8-node quadratic quadrilateral shell |
| EQ.24: | 6-node quadratic triangular shell |
| EQ.25: | Belytschko-Tsay shell with thickness stretch |
| EQ.26: | Fully integrated shell with thickness stretch |
| EQ.27: | C0 triangular shell with thickness stretch |
| EQ.29: | Cohesive shell element for edge-to-edge connection of shells. See Remark 12 . |
| EQ.-29: | Cohesive shell element for edge-to-edge connection of shells (more suitable for pure shear). See Remark 12 . |
| EQ.41: | Mesh-free (EFG) shell local approach. (more suitable for crashworthiness analysis) |
| EQ.42: | Mesh-free (EFG) shell global approach. (more suitable for metal forming analysis) |
| EQ.43: | Mesh-free (EFG) plane strain formulation (x - y plane) |
| EQ.44: | Mesh-free (EFG) axisymmetric solid formulation (x - y plane, y -axis of symmetry) |
| EQ.46: | Cohesive element for two-dimensional plane strain, plane stress, and area-weighted axisymmetric problems (use with type 14 shells). See Remark 15. |
| EQ.47: | Cohesive element for two-dimensional volume- |

| VARIABLE | DESCRIPTION |
|----------|---|
| | weighted axisymmetric problems (use with type 15 shells). See Remark 15. |
| EQ.52: | Plane strain (x - y plane) XFEM, base element type 13 |
| EQ.54: | Shell XFEM, base element type defined by BASELM (default 16) |
| EQ.55: | 8-node singular plane strain (x - y plane) finite element. See Remark 11. |
| EQ.98: | Interpolation shell |
| EQ.99: | Simplified linear element for time-domain vibration studies. See Remark 4. |
| EQ.101: | User defined shell |
| EQ.102: | User defined shell |
| EQ.103: | User defined shell |
| EQ.104: | User defined shell |
| EQ.105: | User defined shell |
| EQ.201: | Isogeometric shells with NURBS. See *ELEMENT_SHELL_NURBS_PATCH. |
| GE.1000: | Generalized shell element formulation (user defined). See *DEFINE_ELEMENT_GENERALIZED_SHELL. |

The type 18 element is only for linear static and normal modes. It can also be used for linear springback in sheet metal stamping. For implicit modal computations element type 14 must be switched to type 15.

Note that the 2D and 3D element types must not be mixed, and different types of 2D elements must not be used together. For example, 2D axisymmetric calculations can use either element types 14 or 15, but these element types must not be mixed together. Likewise, the plane strain element type must not be used with either the plane stress element or the axisymmetric element types. In 3D, the different shell elements types, i.e., 1-11 and 16, can be freely mixed together.

SHRF Shear correction factor which scales the transverse shear stress. The shell formulations in LS-DYNA, with the exception of the BCIZ and DK elements, are based on a first order shear deformation theory that yields constant transverse shear strains which violates the condition of zero traction on the top and

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | bottom surfaces of the shell. The shear correction factor is attempt to compensate for this error. A suggested value is 5/6 for isotropic materials. This value is incorrect for sandwich or laminated shells; consequently, laminated/sandwich shell theory is now an option in some of the constitutive models, that is material types 22, 54, and 55. |
| NIP | <p>Number of through thickness integration points. Either Gauss (default) or Lobatto integration can be used. The flag for Lobatto integration can be set on the control card, *CONTROL_SHELL. The location of the Gauss and Lobatto integration points are tabulated below.</p> <p>EQ.0.0: set to 2 integration points for shell elements.</p> <p>EQ.1.0: 1 point (no bending)</p> <p>EQ.2.0: 2 point</p> <p>EQ.3.0: 3 point</p> <p>EQ.4.0: 4 point</p> <p>EQ.5.0: 5 point</p> <p>EQ.6.0: 6 point</p> <p>EQ.7.0: 7 point</p> <p>EQ.8.0: 8 point</p> <p>EQ.9.0: 9 point</p> <p>EQ.10.: 10 point</p> <p>GT.10.: trapezoidal or user defined rule</p> <p>Through thickness integration for the two-dimensional elements (options 12-15 above) is not meaningful; consequently, the default is equal to 1 integration point. Fully integrated two-dimensional elements are available for options 13 and 15 (but not 12 and 14) by setting NIP equal to a value of 4, corresponding to a 2 by 2 Gaussian quadrature. If NIP is 0 or 1 and the *MAT_SIMPLIFIED_JOHNSON_COOK model is used, then a resultant plasticity formulation is activated. NIP is always set to 1 if a constitutive model based on resultants is used.</p> |
| PROPT | <p>Printout option (**NOT ACTIVE**):</p> <p>EQ.1.0: average resultants and fiber lengths,</p> <p>EQ.2.0: resultants at plan points and fiber lengths,</p> |

| VARIABLE | DESCRIPTION |
|----------|---|
| QR/IRID | <p>EQ.3.0: resultants, stresses at all points, fiber lengths.</p> <p>Quadrature rule or Integration rule ID, see *INTEGRATION_SHELL:</p> <p>LT.0.0: absolute value is specified rule number,</p> <p>EQ.0.0: Gauss/Lobatto (up to 10 points are permitted),</p> <p>EQ.1.0: trapezoidal, not recommend for accuracy reasons.</p> |
| ICOMP | <p>Flag for orthotropic/anisotropic layered composite material model. This option applies to material types 21, 22, 23, 33, 33_96, 34, 36, 40, 41-50, 54, 55, 58, 59, 103, 103_P, 104, 108, 116, 122, 133, 135, 135_PLC, 136, 157, 158, 190, 219, 226, 233, 234, 235, 242, and 243. For these material types, see *PART_COMPOSITE as an alternative to *SECTION_SHELL. Note: Please refer to <i>Remark 5</i> under *MAT_034 for additional information specific to fiber directions for fabrics.</p> <p>EQ.1: a material angle in degrees is defined for each through thickness integration point. Thus, each layer has one integration point.</p> |
| SETYP | Not used (obsolete). |
| T1 | Shell thickness at node n_1 , unless the thickness is defined on the *ELEMENT_SHELL_OPTION card. |
| T2 | Shell thickness at node n_2 , see comment for T1 above. |
| T3 | Shell thickness at node n_3 , see comment for T1 above. |
| T4 | Shell thickness at node n_4 , see comment for T1 above. |
| NLOC | <p>Location of reference surface (shell mid-thickness) for three dimensional shell elements. If nonzero, the offset distance from the plane of the nodal points to the reference surface of the shell in the direction of the shell normal vector is a value,</p> $\text{offset} = -0.50 \times \text{NLOC} \times (\text{average shell thickness}).$ <p>Except for Mortar contacts, this offset is not considered in the contact subroutines unless CNTCO is set to 1 in *CONTROL_SHELL. Alternatively, the offset can be specified by using the OFFSET option in the *ELEMENT_SHELL input section. For Mortar contacts, NLOC or OFFSET determines the location of the</p> |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | contact surface regardless the value of CNTCO. EQ.1.0: nodes are located at top surface of shell, EQ.0.0: nodes are located at mid-thickness of shell (default), EQ.-1.0: nodes are located at bottom surface of shell. |
| MAREA | Non-structural mass per unit area. This is additional mass which comes from materials such as carpeting. This mass is not directly included in the time step calculation. Another and often more convenient alternative for defining distributed mass is by the option: *ELEMENT_MASS_PART, which allows additional non-structural mass to be distributed by an area weighted distribution to all nodes of a given part ID). |
| IDOF | Treatment of through thickness strain. LT.0: Same as IDOF = 3 but the contact pressure is averaged over a time -IDOF in order to reduce noise and thus improve stability. EQ.1: The thickness field is continuous across the element edges for metalforming applications. This option applies to element types 25 and 26. EQ.2: The thickness field is discontinuous across the element edges. This is necessary for crashworthiness simulations due to shell intersections, sharp included angles, and non-smooth deformations. This option applies to element types 25, 26 and 27 and is mandatory for element type 27. This is the default for these element types. EQ.3: The thickness strain is governed by the contact stress, meaning that the strain is adjusted for the through thickness stress to equilibrate the contact pressure. This option applies to element types 2, 4, and ±16 . |
| EDGSET | Edge node set required for shell type seatbelts. Input an ordered set of nodes along one of the transverse edges of a seatbelt. If there is no retractor associated with a belt, the node set can be on either edge. If the retractor exists, the edge node set must be on the retractor side and input in the same sequence as the retractor node set. Therefore, another restriction on the seatbelt usage is that each belt has its own section definition and, therefore, a unique part ID. See Figure 17-16 in the section *ELEMENT_SEATBELT for additional clarification. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| B1 | β_1 , material angle at first integration point |
| B2 | β_2 , material angle at second integration point |
| B3 | β_3 , material angle at third integration point |
| : | : |
| BNIP | $\beta_{n\text{ip}}$, material angle at NIP th integration point. |
| DX, DY | Normalized dilation parameters of the kernel function in X and Y directions. The normalized dilation parameters of the kernel function are introduced to provide the smoothness and compact support properties on the construction of the mesh-free shape functions. Values between 1.0 and 2.0 are recommended. Values smaller than 1.0 are not allowed. Larger values will increase the computation time and will sometimes result in a divergence problem. |
| ISPLINE | Replace the choice for the EFG kernel functions definition in *CONTROL_EFG. This allows users to define different ISPLINE in different sections. |
| IDILA | Replace the choice for the normalized dilation parameter definition in *CONTROL_EFG. This allows users to define different IDILA in different sections. |
| IEBT | Essential boundary condition treatment EQ.1: Full transformation (default for ELFORM= 42) EQ.-1: Without full transformation (default for ELFORM = 41) EQ.3: Coupled FEM/EFG EQ.7: Maximum entropy approximation |
| IDIM | For mesh-free shell local approach (ELFORM = 41) EQ.1: First-kind local boundary condition method EQ.2: Gauss integration (default) For mesh-free shell global approach (ELFORM = 42) EQ.1: First-kind local boundary condition method (default) EQ.2: Second-kind local boundary condition method |

| VARIABLE | DESCRIPTION |
|------------------------|--|
| ITHELFM | Thermal shell formulation EQ.0: Default is governed by THSHEL on *CONTROL_SHELL EQ.1: Thick thermal shell EQ.2: Thin thermal shell |
| CMID | Cohesive material ID (only *MAT_COHESIVE_TH is available) |
| BASELM | Base element type for XFEM (type 13 for 2D, types 2 and 16 for shell) |
| DOMINT | Option for domain integration in XFEM: EQ.0: Phantom element integration EQ.1: Subdomain integration with triangular local boundary integration (available in 2D only) |
| FAILCR | Option for different failure criteria: EQ.1: Maximum tensile stress EQ.2: Maximum shear stress EQ.-1: Effective plastic strain (EPS). EQ.-2: Crack length dependent EPS. See Remark 14 . |
| PROPCR | Not used |
| If FAILCR.EQ.-2 | |
| FS | Initial failure plastic strain |
| (LS)/FS1 | FS1 is the final failure plastic strain. |
| (NC)/CL | CL is the crack length at which the failure strain is FS1. |
| Else | |
| FS | Failure strain/failure critical value |
| LS/(FS1) | LS is the length scale for strain regularization. A value greater than 0 activates regularization. Available for FAILCR = -1. |

| VARIABLE | DESCRIPTION |
|---------------|--|
| NC/(CL) | NC is the number of cracks allowed in the part. |
| End if | |
| NIPP | Number of in-plane integration points for user-defined shell (0 if resultant/discrete element) |
| NXDOF | Number of extra degrees of freedom per node for user-defined shell |
| IUNF | Flag for using nodal fiber vectors in user-defined shell: EQ.0: Nodal fiber vectors are not used. EQ.1: Nodal fiber vectors are used. |
| IHGF | Flag for using hourglass stabilization (NIPP is greater than 0) EQ.0: Hourglass stabilization is not used EQ.1: LS-DYNA hourglass stabilization is used EQ.2: User-defined hourglass stabilization is used EQ.3: Same as 2, but the resultant material tangent moduli are passed |
| ITAJ | Flag for setting up finite element matrices (NIPP is greater than 0) EQ.0: Set up matrices with respect to isoparametric domain EQ.1: Set up matrices with respect to physical domain |
| LMC | Number of property parameters |
| NHSV | Number of history variables |
| ILOC | Coordinate system option: EQ.0: Pass all variables in LS-DYNA local coordinate system EQ.1: Pass all variables in global coordinate system |
| XI | First isoparametric coordinate |
| ETA | Second isoparametric coordinate |
| WGT | Isoparametric weight |
| P1 | First user defined element property. |

| VARIABLE | DESCRIPTION |
|-----------------|---------------------------------------|
| P2 | Second user defined element property. |
| : | : |
| PLCM | LCMth user defined element property. |

Location of through thickness Lobatto integration points. The coordinate is referenced to the shell midsurface at location 0. The inner surface of the shell is at -1 and the outer surface is at +1.

Remarks:

1. **Formulations.** The default shell formulation is 2 unless overridden by THEORY in *CONTROL_SHELL. ELFORM in *SECTION_SHELL overrides THEORY.

For implicit calculations the following element formulations are implemented: 2, 5, 6, 10, 12,12, 13, 14, 15, 16, -16, 17, 18, 20, 21, 22, 23, 24, 25, 26, 27, 29, 41, 42, 55.

If another element formulation is requested for an implicit analysis, LS-DYNA will substitute one of the above in place of the one chosen.

2. **Linear Elements Type 18 and 20.** The linear elements consist of an assembly of membrane and plate elements. They have six degrees of freedom per node

and can, therefore, be connected to beams, or used in complex shell surface intersections. These elements possess the required zero energy rigid body modes and have exact constant strain and curvature representation, that is they pass all the first order patch tests. In addition, the elements have behavior approaching linear bending (cubic displacement) in the plate-bending configuration.

- a) The membrane component is based on an 8-node/6-node isoparametric mother element which incorporates nodal in-plane rotations through cubic displacement constraints of the sides [Taylor 1987; Wilson 2000].
 - b) The plate component of element 18 is based on the Discrete Kirchhoff Quadrilateral (DKQ) [Batoz 1982]. Because the Kirchhoff assumption is enforced, the DKQ is transverse-shear rigid and can only be used for thin shells. No transverse shear stress information is available. The triangle is based on a degeneration of the DKQ. This element sometimes gives slightly lower eigenvalues when compared with element type 20.
 - c) The plate component of element 20 is based on the 8-node serendipity element. At the mid-side, the parallel rotations and transverse displacements are constrained and the normal rotations are condensed to yield a 4-node element. The element is based on thick plate theory and is recommended for thick and thin plates.
 - d) The quadrilateral elements contain a warpage correction using rigid links.
 - e) The membrane component of element 18 has a zero energy mode associated with in-plane rotations. This is automatically suppressed in a non-flat shell by the plate stiffness of the adjacent elements. In contrast, element 20 has no spurious zero energy modes.
3. **Linear Shear Element (22).** The linear shear panel element resist tangential in plane shearing along the four edges and can only be used with the elastic material constants of *MAT_ELASTIC. Membrane forces and out-of-plane loads are not resisted.
 4. **Simplified Element for Time Domain Vibrations (99).** Element type 99 is intended for vibration studies carried out in the time domain. These models may have very large numbers of elements and may be run for relatively long durations. The purpose of this element is to achieve substantial CPU savings. This is achieved by imposing strict limitations on the range of applicability, thereby simplifying the calculations:
 - a) Elements must be rectangular; all edges must parallel to the global x -, y - or z -axis;

- b) Small displacement, small strain, negligible rigid body rotation;
- c) Elastic material only.

If these conditions are satisfied, the performance of the element is similar to the fully integrated shell (ELFORM = 16) but at less CPU cost than the default Belytschko-Tsay shell element (ELFORM = 2). Single element torsion and in-plane bending modes are included; meshing guidelines are the same as for fully integrated shell elements.

No damping is included in the element formulation (such as volumetric damping). It is strongly recommended that damping be applied with keywords such as *DAMPING_PART_MASS or *DAMPING_FREQUENCY_RANGE.

5. **2D Formulations.** For 2D formulations (12-15, 46, 47), nodes must lie in the global x - y plane, so the z -coordinate must be zero. Furthermore, the element normal should be in positive z direction. For axisymmetric element formulations, the global y -axis is taken as the axis of symmetry and all nodes must have x -coordinate values greater than or equal to 0.

Shell thickness values on [Card 2](#) are ignored by formulations 13, 14, and 15. For formulation 14 input values of loads, lumped masses, discrete element stiffnesses, etc. in axisymmetric models are interpreted as values per unit circumference (that is per unit length in the circumferential direction) whereas for formulation 15 they are interpreted per radian. Output of forces for shell formulation 15 are in units of force per radian in the output files, such as bndout, nodfor, secforc, spcforc, and rforc. The units of forces output for shell formulation 14 are, at present, inconsistent. For defining contact in 2D simulations, see the entry for the *CONTACT_2D keyword.

6. **Shells with Thickness Stretch.** Shell element formulation 25 and 26 are the fully integrated shell element based on the Belytschko-Tsay element but with two additional degrees of freedom allowing for a linear variation of strain through the thickness. By default, the thickness field is continuous across the element edges implying that there can be no complex intersections since this would lock up the structure. It assumes a relatively flat surface and is intended primarily for sheets in metal forming. By specifying IDOF = 2, the thickness field is decoupled between elements which makes the element suited for crash. If there are any thickness stretch triangles (formulation 27), IDOF must be set to 2.
7. **Seatbelts.** Users must input a set of nodes along one of the transverse edges of a seatbelt. If there is no retractor associated with a belt, the node set can be on either edge. If the retractor exists, the edge should be on the retractor side and input in the same sequence of retractor node set. Therefore, another re-

striction on the seatbelt usage is each belt has its own section definition and a different part.

8. **Fracture.** XFEM 2D and shell formulations are recommended for brittle or semi-brittle fracture with pre-crack (see *BOUNDARY_PRECRACK) or with geometry imperfection such as a notch or a hole. XFEM shell formulation can be used for ductile fracture analysis with regularized effective plastic strain criterion.
9. **Discrete Kirchoff Theory Shell (17).** Shell element formulation 17 (DKT) is based on discrete Kirchhoff theory. It neglects out-of-plane shear strain energy and is thus valid only for thin plates where shear strain energy is negligible compared to bending energy.
10. **Limitations of Area-Weight Shell (14).** The exact stiffness matrix for the area-weighted shell formulation type 14 is nonsymmetric. The nonsymmetric terms are dropped for computational efficiency, making this formulation unsuitable for implicit linear analysis and eigenvalue analysis. It may, however, be used effectively for implicit nonlinear analysis.

For explicit dynamics, viscous hourglass limits high frequency noise that may otherwise lead to nonphysical element distortion when nodes are on or near the axis of symmetry. Viscosity can be added to type 6 or 7 hourglass control by using $VDC > 0$ under the *HOURGLASS keyword. Alternatively, type 1 hourglass control is viscous.

11. **Eight Node Singular Shell (55).** The eight-noded singular element for fracture analysis is based on the eight-noded quadratic quadrilateral element. There are two ways to include the singularity around the crack tip:
 - a) Move the two mid-nodes on the edges connected to the crack tip to the quarter location and obtain a strain singularity of $1/\sqrt{r}$
 - b) Collapse the three nodes on one side of a quadrilateral element to the crack tip (but the three nodes remain independent) and move the two neighboring mid-nodes to the quarter location to obtain a strain singularity of $1/r$.

This element uses 3×3 quadrature and is available to both implicit and explicit analyses.

12. **Cohesive Shell (+/-29).** Element type +/-29 is a cohesive element that models cohesive interfaces between shell element edges. The element takes bending forces into account and uses drilling force stabilization.

Consider two shell elements in the same plane with nodes $m_1, m_2, m_3, m_4, n_1, n_2, n_3,$ and n_4 such that the (m_3, m_4) edge and the (n_1, n_2) edge are connected through a cohesive shell having nodes $m_4, m_3, n_2,$ and n_1 ; see [Figure 37-23](#). The initial area of the cohesive element may be zero, in which case density is defined in terms of the length of the single connecting edge.

Element type +/-29 works similarly to solid element type 20. For example, extruding the two non-cohesive shells in their respective normal directions defines two 8 node solids. The cohesive mid-surface is located between the opposing faces of the solids, and tractions are calculated in four mid-surface points using differences of displacements between the opposing faces, giving rise to nodal forces and moments in the cohesive shell nodes $m_4, m_3, n_2,$ and n_1 . Additional details can be found in the Theory Manual.

Difference between type 29 and -29: In both formulations, the cohesive coordinate system direction q_2 is defined by the midpoints of the (n_1, m_4) and (n_2, m_3) edges. Type 29 defines the cohesive midsurface normal q_3 using the midpoints on the far side edges (m_1, m_2) and (n_3, n_4) , while type -29 defines q_1 to be the mean of the neighboring element normals. Thus, in pure out-of-plane shear, type 29 will initially have pure tangential traction that turns into a normal traction as the separation increases, while type -29 will only have tangential traction.

Cohesive shell formulations +/-29 output three tractions having units of force per unit area into the d3plot database rather than the usual six stress components. The out-of-plane shear traction replaces the x-stress (mode III), the in-plane shear traction replaces the y-stress (mode II), and the traction in the normal direction replaces the z-stress (mode I).

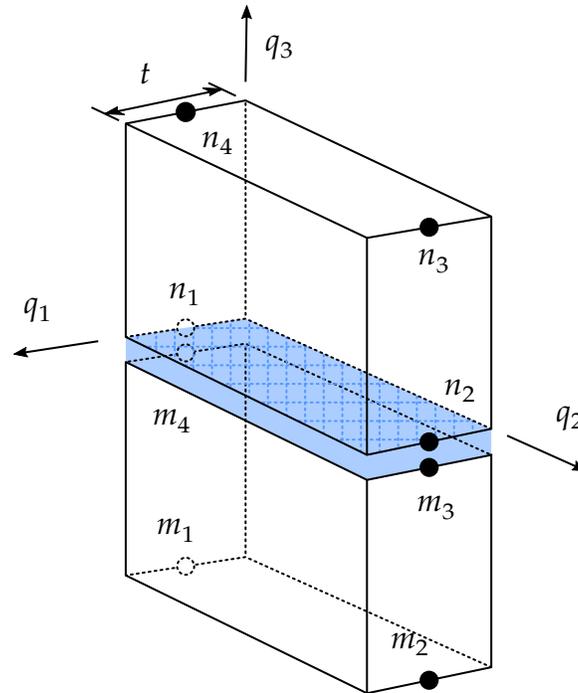

Figure [37-23]. Cohesive interface coordinate system for element type +/-29

13. **Accurate fully-integrated shell (-16).** Accuracy issues have been observed in shell formulation 16 under large deformations/rotations over a single time step. Formulation -16 is a correspondently enhanced version of formulation 16. Formulation 16 is unchanged to maintain back compatibility and, although, element -16 is supported in explicit mode it is primarily intended for implicit time integration. A strongly objective version can be activated by combining `ELFORM = -16` and `IACC = 1` on `*CONTROL_ACCURACY`, thereby ensuring that arbitrarily large rigid body rotation in a single step will transform stresses correctly and not generate any spurious strains.
14. **XFEM ductile fracture.** This feature is supported by a joint research among Honda, JSOL and LSTC. For `FAILCR = -2`, the failure strain is given by:

$$EPS = FS + (FS1 - FS) \times \min(L/CL, 1.0)$$

15. Like cohesive solids, plane strain and axisymmetric cohesive formulations 46 and 47 output three tractions having units of force per unit area into the `d3plot` database rather than the usual six stress components. The in plane shear traction along the 1-2 edge replaces the x-stress, the orthogonal in plane shear traction replaces the y-stress, and the traction in the normal direction replaces the z-stress.

Example:

```

***SECTION_SOLID_{OPTION}**

Available options include:

<BLANK>

EFG

SPG

Purpose: Define section properties for solid continuum and fluid elements.

Card Summary:

Card Sets. For each unique solid section, include one set of data cards. The EFG option and the SPG option cannot both appear in the same model. This input ends at the next keyword ("*") card.

Card 1. This card is required.

| | | | | | | | |
|-------|--------|-----|--|--|--|--|--|
| SECID | ELFORM | AET | | | | | |
|-------|--------|-----|--|--|--|--|--|

Card 2a.1. This card is included if and only if the EFG keyword option is used.

| | | | | | | | |

VARIABLE

DESCRIPTION

SECID

Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.

ELFORM

Element formulation options. [Remark 2](#) enumerates the element formulations available for implicit calculations:

EQ.-2: Fully integrated S/R solid intended for elements with poor aspect ratio, accurate formulation (see [Remark 15](#))

EQ.-1: Fully integrated S/R solid intended for elements with poor aspect ratio, efficient formulation (see [Remark 15](#))

EQ.0: 1 point corotational for *MAT_MODIFIED_HONEY-COMB (see [Remark 3](#))

EQ.1: Constant stress solid element: default element type. By specifying hourglass type 10 with this element, a Cosserat Point Element is invoked, see *CONTROL_HOURLGLASS

EQ.2: Fully integrated S/R solid (see [Remark 4](#))

EQ.3: Fully integrated quadratic 8 node element with nodal rotations

EQ.4: S/R quadratic tetrahedron element with nodal rotations

EQ.5: 1 point ALE

| VARIABLE | DESCRIPTION |
|-----------------|--|
| EQ.6: | 1 point Eulerian |
| EQ.7: | 1 point Eulerian ambient |
| EQ.8: | Acoustic |
| EQ.9: | 1 point corotational for *MAT_MODIFIED_HONEY-COMB (see Remark 3) |
| EQ.10: | 1 point tetrahedron (see Remark 1) |
| EQ.11: | 1 point ALE multi-material element |
| EQ.12: | 1 point integration with single material and void |
| EQ.13: | 1 point nodal pressure tetrahedron (see Remark 14) |
| EQ.14: | 8 point acoustic |
| EQ.15: | 2 point pentahedron element (see Remark 1) |
| EQ.16: | 4 or 5 point 10-noded tetrahedron (see Remark 13). By specifying hourglass type 10 with this element, a Cosserat Point Element is invoked; see *CONTROL_HOURLASS. |
| EQ.17: | 10-noded composite tetrahedron (see Remark 13) |
| EQ.18: | 8 point enhanced strain solid element for linear statics only (see Remark 4) |
| EQ.19: | 8-noded, 4 point cohesive element (see Remarks 1 and 6) |
| EQ.20: | 8-noded, 4 point cohesive element with offsets for use with shells (see Remarks 1, 6, and 8) |
| EQ.21: | 6-noded, 1 point pentahedron cohesive element (see Remarks 1 and 7) |
| EQ.22: | 6-noded, 1 point pentahedron cohesive element with offsets for use with shells (see Remarks 1, 7, and 8) |
| EQ.23: | 20-node solid formulation |
| EQ.24: | 27-noded, fully integrated S/R quadratic solid element |
| EQ.25: | 21-noded, quadratic pentahedron |
| EQ.26: | 15-noded, quadratic tetrahedron |
| EQ.27: | 20-noded, cubic tetrahedron |
| EQ.28: | 40-noded, cubic pentrahedron |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | EQ.29: 64-noded, cubic hexahedron |
| | EQ.41: Mesh-free (EFG) solid formulation (see Remark 16) |
| | EQ.42: Adaptive 4-noded mesh-free (EFG) solid formulation (see Remark 16) |
| | EQ.43: Mesh-free enriched finite element |
| | EQ.45: Tied mesh-free enriched finite element |
| | EQ.47: Smoothed particle Galerkin method (see Remark 17) |
| | EQ.98: Interpolation solid |
| | EQ.99: Simplified linear element for time-domain vibration studies (See Remark 5) |
| | EQ.101: User defined solid |
| | EQ.102: User defined solid |
| | EQ.103: User defined solid |
| | EQ.104: User defined solid |
| | EQ.105: User defined solid |
| | EQ.115: 1 point pentahedron element with hourglass control |
| | GE.201: Isogeometric solids with NURBS. (See *ELEMENT_SOLID_NURBS_PATCH) |
| | GE.1000: Generalized user-defined solid element formulation (See *DEFINE_ELEMENT_GENERALIZED_SOLID) |
| AET | Ambient Element type: Can be defined for ELFORM 7, 11 and 12. |
| | EQ.0: Non-ambient |
| | EQ.1: Temperature (not currently available) |
| | EQ.2: Pressure and temperature (not currently available) |
| | EQ.3: Pressure outflow (obsolete) |
| | EQ.4: Pressure inflow/outflow (Default for ELFORM 7) |
| | EQ.5: Receptor for blast load (See *LOAD_BLAST_ENHANCED. Available only for ELFORM = 11) |

EFG Card. Additional card for the EFG keyword option. See *CONTROL_EFG.

| Card 2a.1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-----------|------|------|------|---------|-------|------|------|--------|
| Variable | DX | DY | DZ | ISPLINE | IDILA | IEBT | IDIM | TOLDEF |

| Default | 1.01 | 1.01 | 1.01 | 0 | 0 | 1 | 2 | 0.01 |

VARIABLE**DESCRIPTION**

DX, DY, DZ

Normalized dilation parameters of the kernel function in x , y and z directions. The normalized dilation parameters of the kernel function are introduced to provide the smoothness and compact support properties on the construction of the mesh-free shape functions. Values between 1.0 and 1.5 are recommended. Values smaller than 1.0 are not allowed. Larger values will increase the computation time and will sometimes result in a divergence problem.

ISPLINE

Replace the choice for the EFG kernel functions definition in *CONTROL_EFG which allows for different spline functions in different sections.

EQ.0: Cubic spline function (default).

EQ.1: Quadratic spline function.

EQ.2: Cubic spline function with circular shape.

IDILA

Replace the choice for the normalized dilation parameter definition in *CONTROL_EFG. This allows users to define different IDILA in different sections.

EQ.0: Maximum distance based on the background elements.

EQ.1: Maximum distance based on surrounding nodes.

IEBT

Essential boundary condition treatment (see [Remarks 9](#) and [10](#)):

EQ.1: Full transformation method (default)

EQ.-1: (w/o transformation)

EQ.2: Mixed transformation method

EQ.3: Coupled FEM/EFG method

| VARIABLE | DESCRIPTION |
|----------|--|
| | EQ.4: Fast transformation method EQ.-4: (w/o transformation) EQ.5: Fluid particle method for E.O.S and *MAT_ELASTIC_-FLUID materials, currently supports only 4-noded background elements. EQ.7: Maximum entropy approximation |
| IDIM | Domain integration method (see Remark 11): EQ.1: Local boundary integration EQ.2: Two-point Gauss integration (default) EQ.3: Improved Gauss integration for IEBT = 4 or -4 EQ.-1: Stabilized EFG integration method (apply to 6-noded cell, 8-noded cell or combination of these two) EQ.-2: EFG fracture method (apply to 4-noded cell and SMP only) |
| TOLDEF | Deformation tolerance for the activation of adaptive EFG Semi-Lagrangian and Eulerian kernel. See Remark 12 . EQ.0.0: Lagrangian kernel GT.0.0: Semi_Lagrangian kernel LT.0.0: Eulerian kernel |

Optional EFG Card. Additional optional card for the EFG keyword option. See *CONTROL_EFG.

| Card 2a.2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-----------|-----|------------------|------|-----|------|-----|------|------|
| Variable | IPS | STIME | IKEN | SF | CMID | IBR | DS | ECUT |
| Type | I | F | I | I | I | I | F | F |
| Default | 0 | 10 ²⁰ | 0 | 0.0 | 0 | 1 | 1.01 | 0.1 |

| VARIABLE | DESCRIPTION |
|----------|---------------------------------------|
| IPS | EQ.0: No pressure smoothing (default) |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| | EQ.1: Moving-least squared pressure recovery (material response is slightly more compressible when turning on this function) |
| STIME | Time to switch from stabilized EFG to standard EFG formulation |
| IKEN | EQ.0: Moving-least-square approximation (default, recommended) EQ.1: Maximum entropy approximation |
| SF | Failure strain, recommended as an extra condition for the crack initiation under slow loading besides the stress-based cohesive law |
| CMID | Cohesive material ID for EFG fracture analysis (only Mode I crack is considered and only *MAT_COHESIVE_TH is available) |
| IBR | EQ.1: No branching allowed EQ.2: Branching is allowed |
| DS | Normalized support defined for computing the displacement jump in fracture analysis |
| ECUT | Define the minimum distance to the node that a crack surface can cut to the edge |

SPG Card. Additional card for the SPG keyword option.

| Card 2b.1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

| Default | 0 | 0 | 0 | 0 | 0 | 0 | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| NIP | Number of integration points for user-defined solid (0 if resultant element) |
| NXDOF | Number of extra degrees of freedom per node for user-defined solid |
| IHGF | Flag for using hourglass stabilization (NIP > 0) EQ.0: Hourglass stabilization is not used EQ.1: LS-DYNA hourglass stabilization is used |

| VARIABLE | DESCRIPTION |
|----------|--|
| | EQ.2: User-defined hourglass stabilization is used EQ.3: Same as 2, but the resultant material tangent moduli are passed |
| ITAJ | Flag for setting up finite element matrices (NIP > 0) EQ.0: Set up matrices with respect to isoparametric domain EQ.1: Set up matrices with respect to physical domain |
| LMC | Number of property parameters |
| NHSV | Number of history variables |

Integration Point Card. Additional card for ELFORM = 101, 102, 103, 104 or 105. Add NIP cards adhering to the format below. Because the default value for NIP is 0, these cards are read only for user-defined elements. See Appendix C.

| Card 4 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

VARIABLE**DESCRIPTION**

P_i i^{th} property parameter

Remarks:

- ESORT to Stabilize Degenerate Solids.** The ESORT variable of the *CONTROL_SOLID keyword can be set to automatically convert degenerate tetrahedrons and degenerate pentahedrons into more suitable solid element formulations. The sorting is performed internally and is transparent to the user. See *CONTROL_SOLID for details.
- Implicit Analysis.** For implicit calculations the following element choices are implemented:
 - EQ.-2: Fully integrated S/R solid element for poor aspect ratios, accurate formulation.
 - EQ.-1: Fully integrated S/R solid element for poor aspect ratios, efficient formulation.
 - EQ.1: Constant stress solid element.
 - EQ.2: Fully integrated S/R solid.
 - EQ.3: Fully integrated 8 node solid with rotational DOFs.
 - EQ.4: Fully integrated S/R 4 node tetrahedron with rotational DOFs.
 - EQ.10: 1 point tetrahedron.
 - EQ.13: 1 point nodal pressure tetrahedron.
 - EQ.15: 2 point pentahedron element.
 - EQ.16: 5 point 10-noded tetrahedron.
 - EQ.17: 10-noded composite tetrahedron.

- EQ.18: 8 point enhanced strain solid element for linear statics only.
- EQ.19: 8-noded, 4 point cohesive element (see [Remarks 1](#) and [6](#))
- EQ.20: 8-noded, 4 point cohesive element with offsets for use with shells (see [Remarks 1](#), [6](#), and [8](#))
- EQ.21: 6-noded, 1 point pentahedron cohesive element (see [Remarks 1](#) and [7](#))
- EQ.22: 6-noded, 1 point pentahedron cohesive element with offsets for use with shells (see [Remarks 1](#), [7](#), and [8](#))
- EQ.23: 20-node solid formulation
- EQ.24: 27-node solid formulation
- EQ.25: 21-noded, quadratic pentahedron
- EQ.26: 15-noded, quadratic tetrahedron
- EQ.27: 20-noded, cubic tetrahedron
- EQ.28: 40-noded, cubic pentahedron
- EQ.29: 64-noded, cubic hexahedron
- EQ.41: Mesh-free (EFG) solid formulation.
- EQ.42: 4-noded mesh-free (EFG) solid formulation.
- EQ.43: Mesh-free enriched finite element.

If another element formulation is requested, LS-DYNA will substitute, when possible, one of the above in place of the one chosen. The type 1 element, constant stress, is generally much more accurate than the type 2 element, the selective reduced integrated element for implicit problems.

3. **Element for Modified Honeycomb Material.** Element formulations 0 and 9, applicable only to *MAT_MODIFIED_HONEYCOMB, behave essentially as nonlinear springs so as to permit severe distortions sometimes seen in honeycomb materials. In formulation 0 the local coordinate system follows the element rotation, whereas in formulation 9 the local coordinate system is based on axes passing through the centroids of the element faces. Formulation 0 is preferred for severe shear deformation where the barrier is fixed in space. If the barrier is attached to a moving body, which can rotate, then formulation 9 is usually preferred.
4. **Elements for Shear and Pressure Locking: Types 2 and 18.** The selective reduced integrated solid element, element type 2, assumes that pressure is constant throughout the element to avoid pressure locking during nearly incompressible flow. However, if the element aspect ratios are poor, shear locking will lead to an excessively stiff response. A better choice, given poor aspect

ratios, is the one point solid element which work well for implicit and explicit calculations. For linear statics, the type 18 enhanced strain element works well with poor aspect ratios. Please note that highly distorted elements should always be avoided since excessive stiffness will still be observed even in the enhanced strain formulations.

5. **Element Type 99 for Vibration.** Element type 99 is intended for vibration studies carried out in the time domain. These models may have very large numbers of elements and may be run for relatively long durations. The purpose of this element is to achieve substantial CPU savings. This is achieved by imposing strict limitations on the range of applicability, thereby simplifying the calculations:

- a) Elements must be cubed; all edges must parallel to the global x -, y - or z -axis;
- b) Small displacement, small strain, negligible rigid body rotation;
- c) Elastic material only

If these conditions are satisfied, the performance of the element is similar to the fully integrated S/R solid (ELFORM = 2) but at less CPU cost than the default solid element (ELFORM = 1). Single element bending and torsion modes are included, so meshing guidelines are the same as for fully integrated solids – e.g. relatively thin structures can be modeled with a single solid element through the thickness if required. Typically, the CPU requirement per element-cycle is roughly two thirds that of the default solid element.

No damping is included in the element formulation (for example volumetric damping). It is strongly recommended that damping be applied, using keywords including *DAMPING_PART_MASS or *DAMPING_FREQUENCY_RANGE.

6. **8-Node Cohesive Element: Type 19.** Element type 19 is a cohesive element. The tractions on the mid-surface defined as the mid-points between the nodal pairs 1-5, 2-6, 3-7, and 4-8 are functions of the differences of the displacements between nodal pairs interpolated to the four integration points. The initial volume of the cohesive element may be zero, in which case, the density may be defined in terms of the area of nodes 1-2-3-4. See Appendix A and the user material description for additional details. See also *MAT_ADD_COHESIVE. See [Remark 18](#) regarding output for cohesive solids.

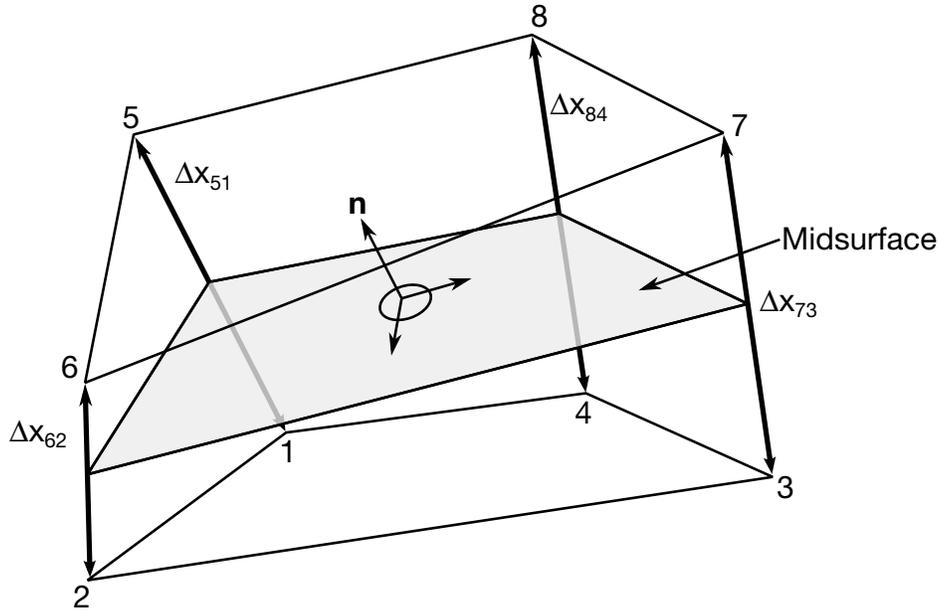

Figure 37-24. Illustration of solid local coordinates.

The tractions are calculated in the local coordinate system defined at the centroid of the element; see [Figure 37-24](#). Defining the rotation matrix from the local to the global coordinate system at time t as $\mathbf{R}(t)$, the initial coordinates as \mathbf{X} , and the current coordinates as \mathbf{x} , the displacements at an integration point are

$$\Delta \mathbf{u} = \mathbf{R}^T(t) \Delta \mathbf{x} - \mathbf{R}^T(0) \Delta \mathbf{X}$$

$$\Delta \mathbf{x} = \sum_{i=1}^4 N_i(s, t) \Delta \mathbf{x}_{i+4, i}$$

$$\Delta \mathbf{X} = \sum_{i=1}^4 N_i(s, t) \Delta \mathbf{X}_{i+4, i}$$

The forces are obtained by integrating the tractions over the mid-surface and rotating them into the global coordinate system. It is the sum over integration points $g = 1, 2, 3, 4$.

$$\mathbf{F}_i = \mathbf{R}(t) \sum_{g=1}^4 \mathbf{T}_g N_i(s_g, t_g) \det(\mathbf{J}_g), \text{ for } 1 \leq i \leq 4, \text{ and } \mathbf{F}_{i+4} = -\mathbf{F}_i$$

where,

\mathbf{T}_g = the traction stress in the local coordinate system

N_i = the shape function of the cohesive element at node i

s_g and t_g = the parametric coordinates of the 4 integration points

J_g = the integration point's portion of the determinate of the cohesive element which is equivalent to the element volume

- 6-Node Cohesive Element: Type 21.** Element type 21 is the pentahedral counterpart to element type 19 with three nodes on the bottom and top surface. The tractions on the mid-surface are defined as the mid-points between the nodal pairs 1-5, 2-6, and 3-7 are functions of the differences of the displacements between nodal pairs interpolated to one integration point. The ordering of the nodal points in *ELEMENT_SOLID is given by:

6-noded (cohesive) pentahedron N1, N2, N3, N3, N5, N6, N7, N7, 0, 0

Setting ESORT > 0 in *CONTROL_SOLID will automatically sort degenerated cohesive elements type 19 to cohesive pentahedron elements type 21. See [Remark 18](#) regarding output for cohesive solids.

- Cohesive Element with Offsets: Types 20 and 22.** Element type 20 is identical to element 19 but with offsets for use with shells. The element is assumed to be centered between two layers of shells on the cohesive element's lower (1-2-3-4) and upper (5-6-7-8) surfaces. The offset distances for both shells are one half the initial thicknesses of the nodal pairs (1-5, 2-6, 3-7, and 4-8) separating the two shells. These offsets are used with the nodal forces to calculate moments that are applied to the shells. Element type 20 in tied contacts will work correctly with the option TIED_SHELL_EDGE_TO_SURFACE, which transmits moments. Other tied options will leave the rotational degrees-of-freedom unconstrained with the possibility that the rotational kinetic energy will cause a large growth in the energy ratio.

Element type 22 is the pentahedron counterpart to element type 20 with three nodes on the bottom and top surface. The ordering of the nodal points in *ELEMENT_SOLID are identical to element type 21 (see [Remark 7](#)). Setting ESORT > 0 in *CONTROL_SOLID will automatically sort degenerated cohesive elements type 20 to cohesive pentahedron elements type 22.

See [Remark 18](#) regarding output for cohesive solids.

- Automatic Sorting for EFG Background Mesh.** The current EFG formulation performs automatic sorting for finite element tetrahedral, pentahedron, and hexahedral elements as the background mesh to identify the mesh-free geometry and provide the contact surface definition in the computation.
- Essential Boundary Conditions.** The mixed transformation method, the coupled FEM/EFG method, and the fast transformation method were implemented in EFG 3D solid formulation. These three features were added to improve the efficiency on the imposition of essential boundary conditions and the transfer of real nodal values and generalized nodal values. The mixed trans-

formation method is equivalent to the full transformation method with improved efficiency. The behavior of the coupled FEM/EFG method is between FEM and EFG. The fast transformation method provides the most efficient and robust results.

11. **IDIM.** For compressible material like foam and soil, $IDIM = 1$ is recommended. For nearly incompressible material like metal and rubber, $IDIM = 2$ (default) is recommended.
12. **TOLDEF.** This field is introduced to improve the negative volume problem usually seen during large deformation analysis. For the same analysis, the larger the magnitude of TOLDEF, the earlier the Semi-Lagrangian or Eulerian kernel is introduced into the EFG computation, so more CPU time is expected. A value between 0.0 and 0.1 is suggested for crashworthiness analysis. Semi-Lagrangian kernel is suggested for the solid materials while Eulerian kernel is suggested for the fluid and EOS materials.
13. **10-Node Tetrahedra: Types 16 and 17.** Formulations 16 and 17 are 10-noded, tetrahedral formulations. The parameter NIPTETS in *CONTROL_SOLID controls the number of integration points for these formulations. Formulation 17 is generally preferred over formulation 16 because, unlike 16, the nodal weighting factors are equal and thus nodal forces from contact and applied pressures are distributed correctly.

When applying loads to 10-noded tetrahedrons via segments, no load will be applied to the mid-side nodes if the segments contain only corner nodes. When defining contact, it is recommended that *CONTACT_AUTOMATIC... be used and the contact surface of the 10-noded tetrahedral part be specified by its part ID. In this manner, mid-side nodes receive contact forces.

If the 10-noded element connectivity is not defined in accordance with [Figure 17-30](#) shown in *ELEMENT_SOLID, the order of the nodes can be quickly changed using a permutation vector specified with *CONTROL_SOLID. If *ELEMENT_SOLID defines 4-noded tetrahedrons, the command *ELEMENT_SOLID_TET4TOTET10 can easily convert them to 10-noded tetrahedrons. Because the characteristic length of a 10-noded tetrahedron is half that of a 4-noded tetrahedron, the time step for the tetrahedrons will be smaller by a factor of 2. The parameter TET10 in 971, when set to 1 in *CONTROL_OUTPUT, causes the full 10-node connectivity to be written to the d3plot and d3part databases.

14. **1-Point Nodal Pressure Tetrahedron: Type 13.** Element type 13 is identical to type 10 but includes additional averaging of nodal pressures, which significantly decreases the chance of volumetric locking. Therefore, it is well suited for applications with incompressible and nearly incompressible material behavior, such as rubber materials or ductile metals with isochoric plastic defor-

mations (e.g. bulk forming). Compared to the standard tetrahedron (type 10), a speed penalty with a maximum of 25% can be observed. For implicit simulations, all material models supported for type 10 are also supported for this element, while for explicit currently material models *MAT_001, 003, 006, 007, 015, 024, 027, 077, 081, 082, 091, 092, 098, 103, 106, 120, 123, 124, 128, 129, 181, 183, 187, 224, 225, and 244 are fully supported. For other materials this element behaves like the type 10 tetrahedron. Type 13 tetrahedral elements that use two different material models should not share nodes because the nodal pressure averaging will cause spurious energy. An exception to this rule is if the different materials have the same bulk modulus.

15. **Fully Integrated S/R Solid Elements for Elements with Poor Aspect Ratio: Types -1 and -2.** Solid formulations -1 and -2 may offer improved behavior over formulation 2 by accounting for poor element aspect ratios in a manner so as to reduce the transverse shear locking effects seen with formulation 2. Type -1 is a more computationally efficient implementation of type -2, but a side-effect is that type -1's resistance to a particular deformation mode, similar to an hourglass mode, is weakened. This side effect is not truly hourglassing behavior, so there is no hourglass energy and the behavior is not affected by hourglass parameters.
16. **EFG Solid Elements: Types 41 and 42.** EFG element type 41 supports 4-node, 6-node and 8-node solid elements. For three-dimensional tetrahedron *r*-adaptive analysis (ADPOPT = 7 in *CONTROL_ADAPTIVE and ADPOPT = 2 in *PART), if the initial mesh is not purely comprised of tetrahedrons, element type 41 should be used instead of 42, causing the mesh to be converted automatically into tetrahedron after the first time step. Element type 42 only supports 4-node tetrahedron mesh and is optimized to achieve better computational efficiency compared to 41.
17. **Smoothed Particle Galerkin (SPG) method: Type 47.** In SPG method, nodes are converted into particles, and 4-node, 6-node and 8-node *solid* elements are supported. The method is suitable for severe deformation problem and failure analysis.
18. **Cohesive Element Output.** Cohesive solids (formulations 19, 20, 21, 22) output three tractions having units of force per unit area into the d3plot database rather than the usual six stress components. The in-plane shear traction along the 1-2 edge replaces the *x*-stress, the orthogonal in plane shear traction replaces the *y*-stress, and the traction in the normal direction replaces the *z*-stress.

***SECTION_SPH_{OPTION}**

Available options include:

<BLANK>

ELLIPSE

INTERACTION (See [Remark 3](#))USER (See [Remark 2](#))

Purpose: Define section properties for SPH particles.

NOTE: This feature is not supported for use in implicit calculations.

Card Sets. For each SPH section add one set of cards 1 or 2 (depending on the keyword option). This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|------|------|------|--------|-------|-------|---------|
| Variable | SECID | CSLH | HMIN | HMAX | SPHINI | DEATH | START | SPHKERN |
| Type | I/A | F | F | F | F | F | F | I |
| Default | none | 1.2 | 0.2 | 2.0 | 0.0 | 1.e20 | 0.0 | 0 |

Ellipse Card. Additional card for ELLIPSE keyword option.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|--------|-------|-------|-------|---|---|
| Variable | HXCSLH | HYCSLH | HZCSLH | HXINI | HYINI | HZINI | | |
| Type | F | F | F | F | F | F | | |

VARIABLE**DESCRIPTION**

SECID

Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.

| VARIABLE | DESCRIPTION |
|----------|--|
| CSLH | Constant used to calculate the initial smoothing length of the particles. The default value works for most problems. Values between 1.05 and 1.3 are acceptable. Taking a value less than 1 is inadmissible. Values larger than 1.3 will increase the computational time. The default value is recommended. See Remark 1 . |
| HMIN | Scale factor for the minimum smoothing length. See Remark 1 . |
| HMAX | Scale factor for the maximum smoothing length. See Remark 1 . |
| SPHINI | Optional initial smoothing length (overrides true smoothing length). With this option LS-DYNA will not calculate the smoothing length during initialization, and the field CSLH is ignored. |
| DEATH | Time imposed SPH approximation is stopped. |
| START | Time imposed SPH approximation is activated. |
| SPHKERN | Option for SPH kernel functions (smoothing functions): EQ.0: Cubic spline kernel function (default). EQ.1: Quintic spline kernel function: higher order smoothing function with bigger support size (recommend to use HMAX = 3.0 or bigger value, only available for FORM = 0, 1, 9 and 10). |
| HXCSLH | Constant applied for the smoothing length in the x -direction for the ellipse case. |
| HYCSLH | Constant applied for the smoothing length in the y -direction for the ellipse case. |
| HZCSLH | Constant applied for the smoothing length in the z -direction for the ellipse case. |
| HXINI | Optional initial smoothing length in the x -direction for the ellipse case (overrides true smoothing length) |
| HYINI | Optional initial smoothing length in the y -direction for the ellipse case (overrides true smoothing length) |
| HZINI | Optional initial smoothing length in the z -direction for the ellipse case (overrides true smoothing length) |

Remarks:

1. **Smoothing Length.** The SPH processor in LS-DYNA employs a variable smoothing length. LS-DYNA computes the initial smoothing length, h_0 , for each SPH part by taking the maximum of the minimum distance between every particle and then scaling this value by CSLH. The recommended values of CSLH should be used so that the radius of the support domain covers more than two layers of SPH particles along each direction. Every particle has its own smoothing length which varies in time according to the following equation:

$$\frac{d}{dt}h(t) = h(t)\nabla \cdot \mathbf{v} ,$$

where $h(t)$ is the smoothing length, and $\nabla \cdot \mathbf{v}$ is the divergence of the flow. The smoothing length increases as particles separate and reduces as the concentration increases. This scheme is designed to hold constant the number of particles in each neighborhood. In addition to being governed by the above evolution equation, the smoothing length is constrained to be between a user-defined upper and lower value,

$$HMIN \times h_0 < h(t) < HMAX \times h_0.$$

Defining a value of 1 for HMIN and 1 for HMAX will result in a constant smoothing length in time and space.

2. **USER Option.** The USER option allows the definition of customized subroutine for the variation of the smoothing length. A subroutine called *hdot* is defined in the file *dyn21.F* (Unix/linux) or *lsdyna.f* (Windows).
3. **Inter-Part Particle Interaction.** There are two fundamental ways that particles from different SPH parts can interact with each other. One way is through “particle approximation” and the other way is through *DEFINE_SPH_TO_SPH_COUPLING. When CONT = 0 in *CONTROL_SPH, “particle approximation” is used for all SPH parts in treating inter-part particle interaction. When CONT = 1 in *CONTROL_SPH, inter-part particle interaction by “particle approximation” occurs only for those SPH parts that use *SECTION_SPH_INTERACTION, while any SPH part that does not make use of *SECTION_SPH_INTERACTION will not participate in inter-part particle interaction, *except* as defined using *DEFINE_SPH_TO_SPH_COUPLING.

*SECTION_TSHELL

Purpose: Define section properties for thick shell elements.

Card Sets. For each TSHELL section include a set of the following cards. This input ends at the next keyword ("*") card.

| | | | | | | | | |
|----------|-------|--------|------|-----|-------|-----|-------|--------|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | SECID | ELFORM | SHRF | NIP | PROPT | QR | ICOMP | TSHEAR |
| Type | I/A | I | F | I | I | F | I | I |
| Default | none | 1 | 1.0 | 2 | 1 | 0.0 | 0 | 0 |

Angle Cards. If ICOMP = 1 specify NIP angles putting 8 on each card. Include as many cards as necessary.

| | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | B1 | B2 | B3 | B4 | B5 | B6 | B7 | B8 |
| Type | F | F | F | F | F | F | F | F |

VARIABLE

DESCRIPTION

SECID

Section ID. SECID is referenced on the *PART card. A unique number or label must be specified.

ELFORM

Element formulation:

EQ.1: one point reduced integration (default),

EQ.2: selective reduced 2 × 2 in plane integration.

EQ.3: assumed strain 2 × 2 in plane integration, see remark below.

EQ.5: assumed strain reduced integration with brick materials

EQ.6: assumed strain reduced integration with shell materials

EQ.7: assumed strain 2 × 2 in plane integration.

SHRF

Shear factor. A value of 5/6 is recommended (see Remark 4).

| VARIABLE | DESCRIPTION |
|-----------------|--|
| NIP | Number of through thickness integration points for the thick shell. See the variable INTGRD in *CONTROL_SHELL for details of the through thickness integration rule. EQ.0: set to 2 integration points. |
| PROPT | Printout option: EQ.1: average resultants and fiber lengths, EQ.2: resultants at plan points and fiber lengths, EQ.3: resultants, stresses at all points, fiber lengths. |
| QR | Quadrature rule: LT.0.0: absolute value is specified rule number, EQ.0.0: Gauss (up to five points are permitted), EQ.1.0: trapezoidal, not recommended for accuracy reasons. |
| ICOMP | Flag for layered composite material mode: EQ.1: a material angle is defined for each through thickness integration point. For each layer one integration point is used. |
| TSHEAR | Flag for transverse shear strain or stress distribution (see Remarks 4 and 5): EQ.0: Parabolic, EQ.1: Constant through thickness. |
| B1 | β_1 , material angle at first integration point. The same procedure for determining material directions is use for thick shells that is used for the 4 node quadrilateral shell. |
| B2 | β_2 , material angle at second integration point |
| B3 | β_3 , material angle at third integration point |
| ⋮ | ⋮ |
| BNIP | β_{NIP} , material angle at NIPth integration point |

Remarks:

1. **Thick Shell Element Formulations.** Thick shell elements are bending elements that have 4 nodes on the bottom face and 4 on the top face. Thick shell element formulations 1, 2 and 6 are extruded thin shell elements and use thin shell material models and have an uncoupled stiffness in the z-direction. Thick shell element formulations 3, 5, and 7 are layered brick elements that use 3D brick material models. Element forms 3 and 5, and 6 are distortion sensitive and should not be used in situations where the elements are badly shaped. A single thick shell element through the thickness will capture bending response, but with element types 3, at least two are recommended to avoid excessive softness.
2. **Formulation 1 Quadrature Quirk.** When using Gaussian quadrature with element formulation 1, the number of integration points is automatically switched to 3 when NIP = 2 and 5 when NIP = 4.
3. **Implicit Time Integration.** Thick shell elements are available for implicit analysis with the exception of thick shell formulation 1. If an element of type 1 is specified in an implicit analysis, it is internally switched to type 2
4. **SHRF Field.** For ELFORM = 1, 2 and 6, the transverse shear stiffness is scaled by the SHRF parameter. Since the strain is assumed to be constant through the thickness, setting SHRF = 5/6 is recommended to obtain the correct shear energy. For ELFORM = 3 and 5, the SHRF parameter is not used, except for material types 33, 36, 133, 135, and 243. For ELFORM = 3, the shear stiffness is assumed constant through the thickness. For ELFORM = 5, 6, and 7, the shear distribution is assumed either parabolic if TSHEAR = 0, or constant if TSHEAR = 1. The parabolic assumption is good when the elements are used in a single layer to model a shell type structure, but the constant option may be better when elements are stacked one on top of the other.
5. **Modeling Composites.** Thick shell elements of all formulations can be used to model layered composites, but element formulations 5 and 6 use assumed strain to capture the complex Poisson's effects and through thickness stress distribution in layered composites. To define the layers of a composite, use QR < 0 to point to *INTEGRATION_SHELL data. Alternatively, the *PART_COMPOSITE_TSHELL keyword offers a simplified way to define the layers.

When modeling composites, laminated shell theory may be used to correct the transverse shear strain if the shear stiffness varies by layer. Laminated shell theory is activated by setting LAMSHT = 4 or 5 on *CONTROL_SHELL. When laminated shell theory is active, the TSHEAR parameter works with all ELFORM values to select either a parabolic or constant shear stress distribution.

*SENSOR

The keyword ***SENSOR** provides a convenient way of activating and deactivating boundary conditions, airbags, discrete elements, joints, contact, rigid walls, single point constraints, and constrained nodes. The sensor capability is new in the second release of version 971 and will evolve in later releases to encompass many more LS-DYNA capabilities and replace some of the existing capabilities such as the airbag sensor logic. The keyword commands in this section are defined below in alphabetical order:

***SENSOR_CONTROL**
***SENSOR_CPM_AIRBAG**
***SENSOR_DEFINE_CALC-MATH**
***SENSOR_DEFINE_ELEMENT**
***SENSOR_DEFINE_FORCE**
***SENSOR_DEFINE_FUNCTION**
***SENSOR_DEFINE_MISC**
***SENSOR_DEFINE_NODE**
***SENSOR_SWITCH**
***SENSOR_SWITCH_CALC-LOGIC**
***SENSOR_SWITCH_SHELL_TO_VENT**

To define and utilize a sensor, three categories of sensor keyword commands are needed as shown in [Figure 38-1](#).

1. Sensors are defined using the ***SENSOR_DEFINE** commands. Sensors provide a time history of model response that may be referred to by ***SENSOR_SWITCH** as a switching criterion. (Note: The time history of any sensor can be output using the **SENSORD** function in ***DEFINE_CURVE_FUNCTION** and ***DATABASE_CURVOUT**.)
 - a) ***SENSOR_DEFINE(_ELEMENT,_FORCE,_MISC,_NODE)**

These commands define a sensor's ID, type, and location..
 - b) ***SENSOR_DEFINE_CALC-MATH, *SENSOR_DEFINE_FUNCTION**

*SENSOR

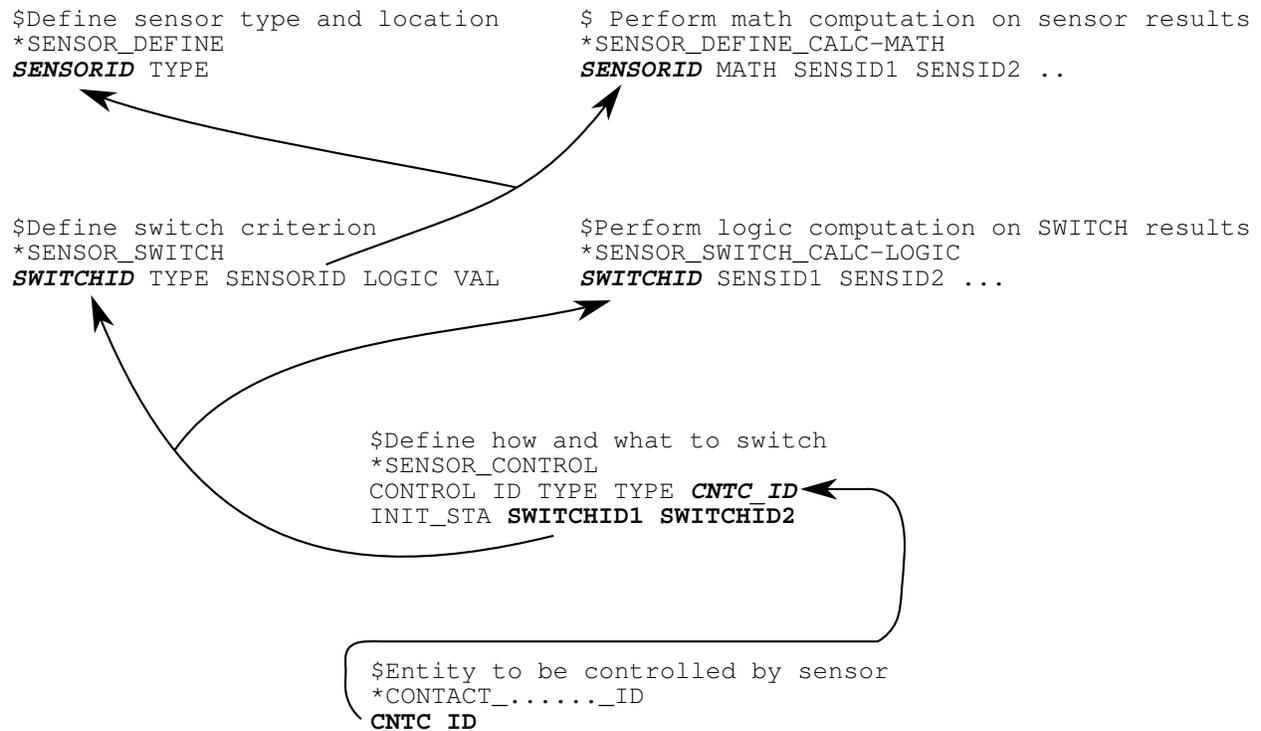

Figure 38-1. Relationship between sensor keyword definitions.

These commands define a sensor whose value is a mathematical expression involving other sensors' values.

2. Sensor switching criterion definition using the ***SENSOR_SWITCH** keyword, which can be combined with the logical calculation command ***SENSOR_SWITCH_CALC-LOGIC** for more complicated definitions. The logic value yielded by this category of commands can be referred by ***SENSOR_CONTROL** to determine if a status switch condition is met.

a) ***SENSOR_SWITCH**

This command compares the numerical value from ***SENSOR_DEFINE** or ***SENSOR_DEFINE_CALC-MATH** with the given criterion to see if a switching condition is met.

b) ***SENSOR_SWITCH_CALC-LOGIC**

This command performs logical calculation on the information from **SENSOR_SWITCH**.

3. Sensor control definition, ***SENSOR_CONTROL**. This category of commands determines how and what to switch based on the logical values from ***SENSOR_SWITCH** and/or ***SENSOR_SWITCH_CALC-LOGIC**.

***SENSOR_CONTROL**

Purpose: This command uses switches (*SENSOR_SWITCH) to toggle on or off the effects of other LS-DYNA keywords, such as *CONTACT or *AIRBAG.

Card Sets. For each sensor control add a pair of Cards 1 and 2. This input ends at the next keyword (“*”) card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|------|--------|---------|------|-------|---|---|
| Variable | CNTLID | TYPE | TYPEID | TIMEOFF | NREP | ESTYP | | |
| Type | I | A | I | I | I | A | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---------|-------|-------|-------|-------|-------|-------|-------|
| Variable | INITSTT | SWIT1 | SWIT2 | SWIT3 | SWIT4 | SWIT5 | SWIT6 | SWIT7 |
| Type | A | I | I | I | I | I | I | I |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| CNTLID | Sensor control ID. |
| TYPE | Entity to be controlled: EQ.“AIRBAG”: *AIRBAG EQ.“BAGVENTPOP”: Opening and closing the airbag venting holes (see Remark 1) EQ.“BELTPRET”: Belt pretensioner firing (see Remark 2) EQ.“BELTRETRA”: Locking the belt retractor (see Remark 2) EQ.“BELTSLIP”: Controlling the slippage of slip ring element (see Remark 3) EQ.“CONTACT”: *CONTACT EQ.“CONTACT2D”: *CONTACT_2D EQ.“CPM”: *AIRBAG_PARTICLE EQ.“DEF2RIG”: *DEFORMABLE_TO_RIGID_AUTOMATIC (see Remark 4) |

| VARIABLE | DESCRIPTION | | | | | | | | |
|------------------|--|-----------------|----------------|----------|---------------|-----------|-----------------------------|-----------|--|
| EQ."ELESET": | Element set; see "ESTYP" below. | | | | | | | | |
| EQ."FUNCTION": | *DEFINE_CURVE_FUNCTION (see Remarks 5 & 6) | | | | | | | | |
| EQ."JOINT": | *CONSTRAINED_JOINT | | | | | | | | |
| EQ."JOINTSTIF": | *CONSTRAINED_JOINT_STIFFNESS | | | | | | | | |
| EQ."M PRESSURE": | *LOAD_MOVING_PRESSURE | | | | | | | | |
| EQ."POREAIR": | *MAT_ADD_PORE_AIR | | | | | | | | |
| EQ."PRESC-MOT": | *BOUNDARY_PRESCRIBED_MOTION | | | | | | | | |
| EQ."PRESC-ORI": | *BOUNDARY_PRESCRIBED_ORIENTATION_RIGID | | | | | | | | |
| EQ."PRESSURE": | *LOAD_SEGMENT_SET | | | | | | | | |
| EQ."RWALL": | *RIGID_WALL | | | | | | | | |
| EQ."SPC": | *BOUNDARY_SPC | | | | | | | | |
| EQ."SPOTWELD": | *CONSTRAINED_SPOTWELD | | | | | | | | |
| TYPEID | ID of entity to be controlled if TYPE is not set to FUNCTION. If TYPE is set to FUNCTION, see Remark 5 . For TYPE = POREAIR, TYPEID is the ID of the part containing material with pore air. | | | | | | | | |
| TIMEOFF | Flag for offset of time in curve: EQ.0: No offset is applied. EQ.1: Offset the abscissa of the time-dependent curve by the time value at which the sensor is triggered. | | | | | | | | |
| | <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: left;">Type Of Control</th> <th style="text-align: left;">Curve Affected</th> </tr> </thead> <tbody> <tr> <td>PRESSURE</td> <td>*LOAD_SEGMENT</td> </tr> <tr> <td>PRESC-MOT</td> <td>*BOUNDARY_PRESCRIBED_MOTION</td> </tr> <tr> <td>PRESC-ORI</td> <td>*BOUNDARY_PRESCRIBED_ORIENTATION_RIGID</td> </tr> </tbody> </table> | Type Of Control | Curve Affected | PRESSURE | *LOAD_SEGMENT | PRESC-MOT | *BOUNDARY_PRESCRIBED_MOTION | PRESC-ORI | *BOUNDARY_PRESCRIBED_ORIENTATION_RIGID |
| Type Of Control | Curve Affected | | | | | | | | |
| PRESSURE | *LOAD_SEGMENT | | | | | | | | |
| PRESC-MOT | *BOUNDARY_PRESCRIBED_MOTION | | | | | | | | |
| PRESC-ORI | *BOUNDARY_PRESCRIBED_ORIENTATION_RIGID | | | | | | | | |
| NREP | Number of repeat of cycle of switches, SWIT _n , defined on card 2. For example, a definition of SWIT _n like "601, 602, 601, 602, 601, 602" can be replaced by setting NREP to 3 and SWIT _n to "601, 602". Setting NREP = -1 repeats the cycle for infinite number of times. Default is 0. | | | | | | | | |
| ESTYP | Type of element set to be controlled. With initial status set to "ON," all the elements included in set TYPEID can be eroded when the controller status is changed to "OFF." When TYPEID is not defined, all elements of type ESTYP in the whole system will | | | | | | | | |

| VARIABLE | DESCRIPTION |
|----------|---|
| | be eroded. |
| | EQ."BEAM": Beam element set. |
| | EQ."DISC": Discrete element set |
| | EQ."SHELL": Thin shell element set |
| | EQ."SOLID": Solid element set |
| | EQ."TSHELL": Thick shell element set |
| INITSTT | Initial status: EQ.On: Initial status is on EQ.Off: Initial status is off |
| SWIT n | ID of n^{th} switch. At the start of the calculation SWIT1 is <i>active</i> , meaning that it controls the state of the feature specified in TYPEID. After SWIT1 triggers, then SWIT2 becomes active; after SWIT2 triggers, then SWIT3 becomes active; this process will continue until the entire stack of switches has been exhausted. |

Remarks:

1. **Activation of Bag Venting.** BAGVENTPOP activates (opens) or deactivates (closes) the venting holes of *AIRBAG_HYBRID and *AIRBAG_WANG_NEFSKE. It overwrites the definitions of PVENT of *AIRBAG_HYBRID and PPOP of *AIRBAG_WANG_NEFSKE. More than one switch can be input to open/close initially closed/opened holes, and then reclose/reopen the holes.
2. **Seatbelt Retractors.** The locking (or firing) of seatbelt retractor (or pretensioner) can be controlled through either general sensor, option BELTRETRA (or BELTPRET), or seatbelt sensors, *ELEMENT_SEATBELT_SENSOR. When BELTRETRA (or BELTPRET) is used, the SBSID i in *ELEMENT_SEATBELT_RETRACTOR (or PRETENSIONER) should be left blank.
3. **Seatbelt Slip Ring.** For a one-way slip ring, a non-zero DIRECT in *ELEMENT_SEATBELT_SLIPRING, BELTSLIP activates the constraint of one-way slippage when the status of *SENSOR_CONTROL is on. When the *SENSOR_CONTROL is turned off, the one-way slippage constraint is deactivated, therefore allowing slippage in both directions.

For a two-way slip ring (DIRECT = 0), BELTSLIP activates slippage in both directions when the status of *SENSOR_CONTROL is on. When the status of *SENSOR_CONTROL is off, the slip ring locks up, allowing no slippage.

4. **Switching Between Rigid and Deformable.** DEF2RIG provides users more flexibility controlling the material switch between rigid and deformable. Status of ON triggers the switch, so the deformable material becomes rigid. Rigidized material can then return to deformable status when status becomes OFF. As many as 7 switches can be input; any of them will change the status triggered by its preceding switch or the initial condition, INTSTT.
5. **Function for Sensor Control.** When the input parameter TYPE of *SENSOR_CONTROL is set to "FUNCTION", the function "SENSOR(cntlid)" as described in *DEFINE_CURVE_FUNCTION takes on a value that depends on the current status of the *SENSOR_CONTROL. That status is either on or off at any given point in time. If the status is on, the value of function SENSOR(cntlid) is set to the integer value 1. If the status is off, the value of function SENSOR(cntlid) is set to the input parameter TYPEID (an integer) as specified in *SENSOR_CONTROL. To help clarify this relationship between *SENSOR_CONTROL and *DEFINE_CURVE_FUNCTION, consider the following example.
6. **Example of Function Sensor Control.** Suppose a *SENSOR_CONTROL defined with CNTLID=101, TYPE="FUNCTION", and TYPEID = -2 has a status of off. Then a *DEFINE_CURVE_FUNCTION defined as "2+3*sensor(101)" will have a value of $2 + 3(-2) = -4$. On the other hand, if the status of the *SENSOR_CONTROL changes to on, the *DEFINE_CURVE_FUNCTION takes on a value of $2 + 3(1) = 5$.

***SENSOR_CPM_AIRBAG**

Purpose: This command will associate a CPM airbag with a sensor switch (see *SENSOR_SWITCH). When the condition flag is raised, the specified CPM airbag will deploy. All time dependent curves used for the CPM airbag are shifted by the activation time including the *AIRBAG_PARTICLE curves for the inflator and vent as well as the *MAT_FABRIC curves for TSRFAC.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|--------|--------|--------|-----|-------|-------|---|
| Variable | CPMID | SWITID | TBIRTH | TDEATH | TDR | DEFPS | RBPID | |
| Type | I | I | F | F | F | I | I | |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| CPMID | Bag ID of *AIRBAG_PARTICLE_ID |
| SWITID | Switch ID of *SENSOR_SWITCH |
| TBIRTH | If SWITID is set, TBIRTH is not active. If SWITID is 0, TBIRTH is the activation time for the bag with ID = CPMID. All of the time dependent curves that are used in this bag will be offset by the value of TBIRTH. |
| TDEATH | Disable the CPMID bag when the simulation time exceeds this value. |
| TDR | If TDR is greater than 0 the bag with ID = CPMID will be rigid starting at first cycle and switch to deformable at time TDR. |
| DEFPS | Part set ID specifying which parts of the bag with ID = CPMID are deformable. |
| RBPID | Part ID of the master rigid body to which the part is merged. |

*SENSOR_DEFINE_CALC-MATH

Purpose: Defines a new sensor with a unique ID. The values associated with this sensor are computed by performing mathematical calculations with the information obtained from sensors defined by the *SENSOR_DEFINE_OPTION.

Math Sensor Cards. Include one additional card for each math sensor. This input ends at the next keyword ("*") card.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|------|-------|-------|-------|-------|-------|-------|
| Variable | SENSID | CALC | SENS1 | SENS2 | SENS3 | SENS4 | SENS5 | SENS6 |
| Type | I | A | I | I | I | I | I | I |

VARIABLE

DESCRIPTION

| | |
|--------------------------|--|
| SENSID | Sensor ID. |
| CALC | Mathematical calculation. See Table 38-2 . |
| SENS _{<i>i</i>} | <i>i</i> th Sensor ID |

Remarks:

All sensors, SENS_{*i*}, defined with either SENSOR_DEFINE_NODE_SET or SENSOR_DEFINE_ELEMENT_SET, must refer to either the same node set or the same element set.

Example:

```

$
$ assume set_2 to have 100 solid elements
*SENSOR_DEFINE_ELEMENT_SET
$ this sensor traces xx-strain of all 100 solid elements in set-2
  91    SOLID    -2      XX    STRAIN
*SENSOR_DEFINE_ELEMENT_SET
$ this sensor traces yy-strain of all 100 solid elements in set-2
  92    SOLID    -2      YY    STRAIN
*SENSOR_DEFINE_ELEMENT_SET
$ this sensor traces zz-strain of all 100 solid elements in set-2
  93    SOLID    -2      ZZ    STRAIN
*SENSOR_DEFINE_CALC-MATH
$ this sensor traces strain magnitudes of all 100 solid elements in set-2
  104  SQRTSQRE    91    92    93    0    0    0
*SENSOR_SWITCH
$ Because ELEMID of *sensor_define_element_set was input as "-2", SWITCH-1 will be
$ turned on if at least one of 100 elements has a strain magnitude>2.0E-4
$ On the other hand, If ELEMID was input as "2", SWITCH-1 will be turned on if
$ all 100 elements have strain magnitudes>2.0E-4
  1    SENSOR    104    GT    2.0E-4    0    0.001
$

```

| <u>FUNCTION</u> | <u>DESCRIPTION</u> | <u>MATHEMATICAL FORM</u> |
|-----------------|--|---|
| ABSSUM | Absolute value of the sum of sensor values | $ \text{SENS1} + \text{SENS2} + \dots $ |
| MIN | The minimum of sensor values | $\min(\text{SENS1}, \text{SENS2}, \dots)$ |
| MAX | The maximum of sensor values | $\max(\text{SENS1}, \text{SENS2}, \dots)$ |
| MAXMAG | The maximum of magnitude of sensor values | $\max(\text{SENS1} , \text{SENS2} , \dots)$ |
| MINMAG | The minimum of the magnitude of sensor values | $\min(\text{SENS1} , \text{SENS2} , \dots)$ |
| MULTIPLY | Multiplication of sensor values; negative for division (performed left to right) | $\text{SENS1} \times \text{SENS2} \times \dots$ |
| SQRE | Summation of squared values of sensor values | $\text{SENS1}^2 + \text{SENS2}^2 + \dots$ |
| SQRTSQRE | Square root of the sum of squared values | $\sqrt{\text{SENS1}^2 + \text{SENS2}^2 + \dots}$ |
| SQRT | Summation of square root of sensor values; negative for subtracting values | $\sqrt{\text{SENS1}} + \sqrt{\text{SENS2}} + \dots$ |
| SUMABS | Summation of absolute sensor values | $ \text{SENS1} + \text{SENS2} + \dots$ |
| SUM | Summation of sensor values; negative for subtracting values | $\text{SENS1} + \text{SENS2} + \dots$ |

Table 38-2. Available mathematical functions.

***SENSOR_DEFINE_ELEMENT_{OPTION}**

Available options include:

<BLANK>

SET

Purpose: Define a strain gage type element sensor that checks the stress, strain, or resultant force of an element or element set.

Element Sensor Cards. Include one of this card for each element sensor or a set of this card and Card 2 for each element set sensor. This input ends at the next keyword ("*") card.

| | | | | | | | | |
|----------|--------|-------|--------|------|-------|-------|----|-----|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | SENSID | ETYPE | ELEMID | COMP | CTYPE | LAYER | SF | PWR |
| Type | I | A | I | A | A | A/I | R | R |

Optional card for SET option. For more than one set sensor, this card must be included for each set sensor even if left blank.

| | | | | | | | | |
|----------|--------|---|---|---|---|---|---|---|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | SETOPT | | | | | | | |
| Type | A | | | | | | | |

VARIABLE

DESCRIPTION

SENSID

Sensor ID.

ETYPE

Element type. Available options include:

EQ.BEAM: beam element.

EQ.SHELL: shell element

EQ.SOLID: solid element

EQ.DISC-ELE: discrete element

EQ.SEATBELT: seatbelt element

EQ.TSHELL: thick shell element

| VARIABLE | DESCRIPTION |
|----------|--|
| ELEMID | Element ID or element set ID when option_SET is active. In case of option_SET, a positive ELEMID requires all elements in set ELEMID to meet the switch condition to switch the status of related *SENSOR_SWITCH. If ELEMID is negative, the status of related *SENSOR_SWITCH will be changed if at least one of elements in set "-ELEMID" meets the switch condition. |
| COMP | <p>Component type. The definition of component, and its related coordinate system, is consistent with that of elout. Leave blank for discrete elements. Available options for elements other than discrete element include:</p> <p>EQ.XX: x-normal component for shells and solids EQ.YY: y-normal component for shells and solids EQ.ZZ: z-normal component for shells and solids EQ.XY: xy-shear component for shells and solids EQ.YZ: yz-shear component for shells and solids EQ.ZX: zx-shear component for shells and solids EQ.AXIAL: axial EQ.SHEARS: local s-direction EQ.SHEART: local t-direction</p> |
| CTYPE | <p>Sensor type. Available options include:</p> <p>EQ.STRAIN: strain component for shells and solids EQ.STRESS: stress component for shells and solids EQ.FORCE: force resultants for beams, seatbelt, or translational discrete element; moment resultant for rotational discrete element EQ.MOMENT: moment resultants for beams EQ.DLEN: change in length for discrete or seatbelt element EQ.FAIL: failure of element, sensor value = 1 when element fails, = 0 otherwise.</p> |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| LAYER | <p>Layer of integration point in shell or thick shell element. Options include:</p> <ul style="list-style-type: none">EQ.BOT: component at lower surface meaning the integration point with the smallest through-the-thickness local coordinateEQ.TOP: component at upper surface meaning the integration point with the largest through-the-thickness local coordinate <p>When CTYPE = STRESS, LAYER could be an integer i to monitor the stress of the i^{th} integration point.</p> |
| SF, PWR | <p>Optional parameters, scale factor and power, for users to adjust the resultant sensor value. The resultant sensor value is</p> $[\text{SF} \times (\text{Original Value})]^{\text{PWR}}$ |
| SETOPT | <p>Option to process set of data when SET option is specified. More details can be found in *SENSOR_DEFINE_NODE_SET. When SETOPT is defined, a single value will be reported and only positive ELEMID is allowed. The single reported value could be</p> <ul style="list-style-type: none">EQ.AVG: the average value of the datasetEQ.MAX: the maximum value of the datasetEQ.MIN: the minimum value of the datasetEQ.SUM: the sum of the dataset |

***SENSOR_DEFINE_FORCE**

Purpose: Define a force transducer type sensor.

Force Sensor Cards. Include one additional card for each force sensor. This input ends at the next keyword ("*") card.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|-------|--------|-----|-----|---|---|---|
| Variable | SENSID | FTYPE | TYPEID | VID | CRD | | | |
| Type | I | A | I | A/I | I | | | |

VARIABLE**DESCRIPTION**

| | |
|--------|---|
| SENSID | Sensor ID. |
| FTYPE | Force type. See Table 38-3 . |
| TYPEID | ID defined in the associated KEYWORD command. See Table 38-3 . |
| VID | Vector along which the forces is measured. EQ.X: x -direction in coordinate system CRD. EQ.Y: y -direction in coordinate system CRD. EQ.Z: z -direction in coordinate system CRD. EQ.XMOMENT: x -direction moment for JOINT, JOINTSTIF, PRESC-MOT or SPC. EQ.YMOMENT: y -direction moment for JOINT, JOINTSTIF, PRESC-MOT or SPC. EQ.ZMOMENT: z -direction moment for JOINT, JOINTSTIF, PRESC-MOT or SPC. VID \in {INT}: vector ID n in coordinate system CRD. |
| CRD | Optional coordinate system, defined by *DEFINE_COORDINATE_NODES, to which vector VID is attached. If blank, the global coordinate system is assumed. |

| FTYPE | TYPEID (Enter ID defined in following KEYWORD commands) | OUTPUT | ASCII FILE |
|--------------|--|---------------------------------------|-------------------|
| AIRBAG | *AIRBAG | Airbag pressure | ABSTAT |
| CONTACT | *CONTACT | Contact force on the slave side | RCFORC |
| CONTACT2D | *CONTACT_2D | Contact force on the slave side | RCFORC |
| CPM | *AIRBAG_PARTICLE | Airbag pressure | ABSTAT_CPM |
| JOINT | *CONSTRAINED_JOINT | Joint force | JNTFORC |
| JOINTSTIF | *CONSTRAINED_JOINT_STIFFNESS | Joint stiffness force | JNTFORC |
| PRESC-MOT | *BOUNDARY_PRESCRIBED_MOTION | Prescribed motion force | BNDOUT |
| RWALL | *RIGIDWALL | Rigid wall force | RWFORC |
| SPC | *BOUNDARY_SPC | SPC reaction force | SPCFORC |
| SPOTWELD | *CONSTRAINED_POINTS | Spot weld force | SWFORC |
| X-SECTION | *DATABASE_CROSS_SECTION | Section force | SECFORC |

Table 38-3. Force transducer type sensor

***SENSOR_DEFINE_FUNCTION**

Purpose: Defines a new sensor with a unique ID. The value associated with this sensor is computed by performing mathematical calculations defined in *DEFINE_FUNCTION, with the information obtained from other sensors defined by the *SENSOR_DEFINE_OPTION.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|------|-------|-------|-------|-------|-------|-------|
| Variable | SENSID | FUNC | SENS1 | SENS2 | SENS3 | SENS4 | SENS5 | SENS6 |
| Type | I | I | I | I | I | I | I | I |

Sensor Cards. Additional Cards needed when SENS1 < -5. Include as many cards as needed to specify all |SENS1| cards.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|--------|--------|--------|--------|--------|
| Variable | SENS7 | SENS8 | SENS9 | SENS10 | SENS11 | SENS12 | SENS13 | SENS14 |
| Type | I | I | I | I | I | I | I | I |

VARIABLE**DESCRIPTION**

| | |
|----------|--|
| SENSID | Sensor ID |
| FUNC | Function ID |
| SENS1 | 1 st sensor ID, the value of which will be used as the 1st argument of function FUNC. If defined as negative, the absolute value of SENS1, SENS1 , is the number of sensors to be input. If SENS1 > 5, additional cards will be needed to input the ID of all sensors. The number of sensors is limited to 15. |
| SENS i | i^{th} Sensor ID, the value of which will be used as the i^{th} argument of function FUNC |

*SENSOR

*SENSOR_DEFINE_MISC

*SENSOR_DEFINE_MISC

Purpose: Trace the value of a miscellaneous item. This card replaces *SENSOR_DEFINE_ANGLE.

Force Sensor Cards. Include one additional card for each miscellaneous sensor. This input ends at the next keyword (“*”) card.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|-------|-----|-----|-----|-----|-----|-----|
| Variable | SENSID | MTYPE | I0 | I1 | I2 | I3 | I4 | I5 |
| Type | I | A | I/A | I/A | I/A | I/A | I/A | I/A |

| <u>VARIABLE</u> | <u>DESCRIPTION</u> |
|-----------------|--|
| SENSID | Sensor ID. |
| MTYPE | Entity to be traced: EQ.ANGLE: Angular accelerometer sensor tracing the angle between two lines, $0^\circ \leq \theta \leq 180^\circ$. The fields I1 and I2 are node numbers defining the 1st line, while I3 and I4 are node numbers defining the 2nd line. EQ.BNDOUT: Boundary condition energy as reported in file “bndout”. I1 is the ID as defined in *BOUNDARY_PRESCRIBED_MOTION EQ.CURVE: The value of a time-dependent curve defined by *DEFINE_CURVE_FUNCTION or *DEFINE_CURVE. I1 is the curve ID. EQ.MATSUM: Information reported in MATSUM for part set I1, including I0.eq.KINETIC: kinetic energy I0.eq.INTERNAL: internal energy I0.eq.ERODEKE: eroded kinetic energy I0.eq.ERODEIE: eroded internal energy EQ.NFAILE: Number of failed elements of type I0 in set I1 will be traced. I0, element type, can be “SOLID” for solid elements, “SHELL” for thin shell elements, “TSHELL” for thick shell elements, “BEAM” for beam elements or |

| VARIABLE | DESCRIPTION |
|---------------|---|
| | "DISC" for discrete elements. I1 is the related element set number. If undefined, the failure of all elements of type I0 will be traced. |
| EQ.RETRACTOR: | The seatbelt retractor payout rate is traced. I1 is the retractor ID. |
| EQ.RIGIDBODY: | Accelerometer sensor tracing the kinematics of a rigid body with id I1. The I2 field specifies which kinematical component is to be traced. It may be set to "TX", "TY", or "TZ" for X, Y, and Z translations and to "RX", "RY", or "RZ" for the X, Y, and Z components of the rotation. The I3 field specifies the kinematics type: "D" for displacement, "V" for velocity and "A" for acceleration. Output is calculated with respect to the global coordinate system when the I4 field is set to "0", its default value; the local rigid-body coordinate system is used when I4 is set to "1". |
| EQ.TIME: | The current analysis time is traced. |
| I1, ..., I5 | See MTYPE. |

***SENSOR_DEFINE_NODE_{OPTION}**

Available options include:

<BLANK>

SET

Purpose: Define an accelerometer type sensor or temperature sensor.

Accelerometer Sensor - This command outputs the relative linear acceleration, velocity, or relative coordinate of node-1 with respect to node-2 along vector VID.

Temperature Sensor – This command outputs the temperature

Node Sensor Cards. Include one additional card for each node sensor. This input ends at the next keyword (“*”) card.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|-------|-------|-----|---|-------|--------|---|
| Variable | SENSID | NODE1 | NODE2 | VID | | CTYPE | SETOPT | |
| Type | I | I | I | I | | A | A | |

VARIABLE**DESCRIPTION**

SENSID

Sensor ID.

NODE1,2

Nodes defining the accelerometer. NODE1 is a node set ID when option_SET is active. In case of option_SET, and when SETOPT is not defined, a positive NODE1 requires all nodes in set NODE1 to meet the switch condition to switch the status of related *SENSOR_SWITCH. If NODE1 is negative, the status of related *SENSOR_SWITCH will be changed if at least one of nodes in set “-NODE1” meets the switch condition.

If CTYPE = TEMP then the temperature at node1 will be output. If both node1 and node2 are defined, then the difference in temperature between these two nodes will be output.

VID

ID of vector along which the nodal values are measured, see *DEFINE_VECTOR. The magnitude of nodal values (coordinate, velocity or acceleration) will be output if VID is 0 or undefined.

| VARIABLE | DESCRIPTION |
|----------|--|
| CTYPE | Output component type (character string). EQ.ACC: acceleration EQ.VEL: velocity EQ.COORD: coordinate EQ.TEMP: temperature |
| SETOPT | Option to process set of data when SET option is specified. When SETOPT is specified, a single value will be reported and only positive NODE1 is allowed. The single reported value could be EQ.AVG: the average value of the dataset EQ.MAX: the maximum value of the dataset EQ.MIN: the minimum value of the dataset EQ.SUM: the sum of the dataset |

Remarks:

1. **Time Evolution of Vector VID.** The vector direction is determined by *DEFINE_VECTOR. This vector direction is updated with time only if the coordinate system CID (see *DEFINE_VECTOR) is defined using *DEFINE_COORDINATE_NODES and the parameter FLAG is set to 1. Otherwise, the vector direction is fixed.
2. **SETOPT.** When SETOPT is not defined for SET option, a list of nodal data will be reported, one for each node in the node set. These reported nodal values can be processed by *SENSOR_DEFINE_FUNCTION and *SENSOR_DEFINE_CALC-MATH, and then result in a list of processed values. These nodal values can be used to determine if the status of SENSOR_SWITCH will be changed. Depending on the sign of NODE1, it can take only one single data point or the whole data sets to meet the switch condition to change the status of the related SENSOR_SWITCH. It should be note that all sensor definitions referred to by these two processing commands must have the same number of data points. The reported nodal values cannot be accessed by commands like *DEFINE_CURVE_FUNCTION, see SENSORD option.

When SETOPT is defined, the nodal values of all nodes in the node set will be processed, depending on the definition of SETOPT, the resulting value is reported as the single sensor value. The reported value can be processed by both *SENSOR_DEFINE_FUNCTION and *SENSOR_DEFINE_CALC-MATH as well as other regular sensors. This reported value can also be accessed by * DE-

FINE_CURVE_FUNCTION using SENSORD option. If the reference node, node2, is needed, NODE2 has to be a node set containing the same number of nodes as node set "-NODE1". The nodes in sets "-NODE1" and "NODE2" have to be arranged in the same sequence so that the nodal value of nodes in set "-NODE1" can be measured with respect to the correct node in set NODE2.

3. When NODE1 is a node that belongs to a rigid body and CCTYPE="ACC", the acceleration recorded by the sensor is not updated every time step but rather only when nodal output is written according to *DATABASE commands. As an alternative, *SENSOR_DEFINE_MISC with MTYPE="RIGIDBODY" updates the sensor data every time step.

***SENSOR_SWITCH**

Purpose: This command compares the value of a sensor, *SENSOR_DEFINE or *SENSOR_DEFINE_CALC-MATH, to a given criterion to check if the switch condition is met. It outputs a logic value of TRUE or FALSE.

Sensor Switch Cards. Include one additional card for each sensor switch. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|---|--------|-------|-------|---------|--------|---|
| Variable | SWITID | | SENSID | LOGIC | VALUE | FILTRID | TIMWIN | |
| Type | I | | I | A | F | I | F | |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| SWITID | Switch ID can be referred directly by *SENSOR_CONTROL to control the status of entities like CONTACT and AIRBAG, or can be referred to by *SENSOR_SWITCH_CALC-LOGIC for logic computation. |
| SENSID | ID of the sensor whose value will be compared to the criterion to determine if a switch condition is met. |
| LOGIC | Logic operator, could be either LT (<) or GT (>). |
| VALUE | Critical value |
| FILTER | Filter ID (optional). Filters may be defined using *DEFINE_FILTER. |
| TIMWIN | Trigger a status change when the value given by the sensor is less than or greater than (depending on LOGIC) the VALUE for a duration defined by TIMWIN. |

***SENSOR_SWITCH_CALC-LOGIC**

Purpose: This command performs a logic calculation for the logic output of up to seven *SENSOR_SWITCH or *SENSOR_SWITCH_CALC-LOGIC definitions. The output is a logic value of either TRUE or FALSE.

Log Cards. Include one additional card for each logic rule. This input ends at the next keyword ("*") card.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|-------|-------|-------|-------|-------|-------|-------|
| Variable | SWITID | SWIT1 | SWIT2 | SWIT3 | SWIT4 | SWIT5 | SWIT6 | SWIT7 |
| Type | | | | | | | | |

VARIABLE**DESCRIPTION**

SWITID

Switch ID can be referred directly by *SENSOR_CONTROL to control the status of entities like CONTACT and AIRBAG, or can be referred to by *SENSOR_SWITCH_CALC-LOGIC for logic computation.

SWITn

Input a positive sensor switch ID for "AND" and negative sensor switch ID for "OR". SWIT1 must always be positive.

This keyword implements standard Boolean logic.

true = 1,
false = 0,
and = multiplication,
or = addition

An expression evaluating to 0 is false, while any expression that evaluates to greater than 0 is true, and, therefore, set to 1.

Example:

Consider 5 switches defined as follows:

switch(11) = true
switch(12) = false
switch(13) = true
switch(14) = true
switch(15) = false.

To evaluate the expression

[switch(11) or switch(12) or switch(13)] and [switch(14) or switch(15)]

and assign the value to switch(103), the following would apply:

```
*SENSOR_SWITCH_CALC-LOGIC
101,11,-12,-13
102,14,-15
103,101,102
```

This translates into

```
switch(101) = switch(11) or switch(12) or switch(13)
              = min((1 + 0 + 1),1)
              = 1 (true)
switch(102) = switch(14) or switch(15)
              = min((1 + 0), 1)
              = 1 (true)
switch(103) = switch(101) and switch(102)
              = min((1 × 1), 1)
              = 1 (true)
```

Therefore,

$$\overbrace{[\text{switch}(11) \text{ or } \text{switch}(12) \text{ or } \text{switch}(13)]}^{\text{switch}(101)=\text{true}} \text{ AND } \overbrace{[\text{switch}(14) \text{ or } \text{switch}(15)]}^{\text{switch}(102)=\text{true}}$$
$$= \text{switch}(103)$$
$$= \text{true}$$

***SENSOR_SWITCH_SHELL_TO_VENT**

Purpose: This option will treat the failed shell elements as vent hole for the airbag defined by *AIRBAG_PARTICLE. The mass escaped from the vent will be reported in the abstat_cpm file.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|-------|-----|---|---|---|---|---|
| Variable | ID | ITYPE | C23 | | | | | |
| Type | I | I | F | | | | | |

Shell Fail Time Cards. Optional Cards for setting time at which shells in a shell list (see *SHELL_LIST) change into vents. This card may be repeated up time 15 times. This input ends at the next keyword ("*") cards.

| Optional | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|------|---|---|---|---|---|
| Variable | SSID | FTIME | C23V | | | | | |
| Type | I | F | F | | | | | |
| Default | none | 0. | C23 | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| ID | Part set ID/Part ID. |
| TYPE | Type for ID: EQ.0: Part EQ.1: Part set |
| C23 | Vent Coefficient (Default = 0.7) LT.0: User defined load curve ID. The vent coefficient will be determined by this pressure-vent_coeff curve. |
| SSID | ID of *SET_SHELL_LIST |
| FTIME | Time to convert shell list to vent. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| C23V | Vent Coefficient. LT.0: User defined load curve ID. The vent coefficient will be determined by this pressure-vent_coeff curve. |

*SET

The keyword ***SET** provides a convenient way of defining groups of nodes, parts, elements, and segments. The sets can be used in the definitions of contact interfaces, loading conditions, boundary conditions, and other inputs. The keyword provides also a convenient way of defining groups of vibration modes to be used in frequency domain analysis. Each set type must have a unique numeric identification. The keyword control cards in this section are defined in alphabetical order:

***SET_BEAM_{OPTION}_{OPTION}**
***SET_BEAM_ADD**
***SET_BOX**
***SET_DISCRETE_{OPTION}_{OPTION}**
***SET_DISCRETE_ADD**
***SET_MODE_{OPTION}**
***SET_MULTIMATERIAL_GROUP_LIST**
***SET_NODE_{OPTION}_{OPTION}**
***SET_NODE_ADD_{OPTION}**
***SET_PART_{OPTION}_{OPTION}**
***SET_PART_ADD**
***SET_SEGMENT_{OPTION}_{OPTION}**
***SET_2D_SEGMENT_{OPTION}_{OPTION}**
***SET_SHELL_{OPTION}_{OPTION}**
***SET_SHELL_ADD**
***SET_SOLID_{OPTION}_{OPTION}**
***SET_SOLID_ADD**
***SET_TSHELL_{OPTION}_{OPTION}**

An additional option **TITLE** may be appended to all the ***SET** keywords. If this option is used then an addition line is read for each section in 80a format which can be used to

***SET**

describe the set. At present, the title serves no purpose other than to perhaps lend clarity to input decks.

The **GENERAL** option is available for set definitions. In this option, the commands are executed in the order defined. For example, the delete option cannot delete a node or element unless the node or element was previously added via a command such as **BOX** or **ALL**.

The **COLLECT** option allows for the definition of multiple sets that share the same ID and combines them into one large set whenever this option is found. If two or more like sets definitions share the same IDs, they are combined if and only if the **_COLLECT** option is specified in each definition. If the **_COLLECT** option is not specified for one or more like set definitions that share identical ID's an error termination will occur. For include files using ***INCLUDE_TRANSFORM** where set offsets are specified, the offsets are not applied for the case where the **_COLLECT** option is present.

*SET_BEAM_{OPTION1}_{OPTION2}

For OPTION1 the available options are:

<BLANK>

GENERATE

GENERATE_INCREMENT

GENERAL

For OPTION2 the available option is:

COLLECT

The GENERATE and GENERATE_INCREMENT options will generate block(s) of beam element ID's between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the set.

Purpose: Define a set of beam elements or a set of seat belt elements (see BSID of *DATABASE_CROSS_SECTION_SET).

Card Summary:

| VARIABLE | DESCRIPTION |
|----------|--|
| BBEG | First beam element ID in block. |
| BEND | Last beam element ID in block. |
| INCR | Beam ID increment. Beam IDs BBEG, BBEG + INCR, BBEG + 2 × INCR, and so on through BEND are added to the set. |

Generalized Beam Element Range Cards. This Card 2 format applies to the GENERAL keyword option. Include as many cards as needed. This input ends at the next keyword ("*") card.

| Card 2d | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|----|----|----|----|----|----|----|
| Variable | OPTION | E1 | E2 | E3 | E4 | E5 | E6 | E7 |
| Type | A | I | I | I | I | I | I | I |

| VARIABLE | DESCRIPTION |
|-------------|--|
| OPTION | Option for GENERAL. See table below. |
| E1, ..., E7 | Specified entity. Each card must have the option specified. See table below. |

The General Option:

The "OPTION" column in the table below enumerates the allowed values for the "OPTION" variable in Card 2 for the GENERAL option. Likewise, the variables E1, ..., E7 refer to the GENERAL option Card 2.

Each of the following operations accept up to 7 arguments, but they may take fewer. Values of E_n left unspecified are ignored.

| OPTION | DESCRIPTION |
|---------------|---|
| ALL | All beam elements will be included in the set. |
| ELEM | Elements E1, E2, E3, ... will be included. |
| DELEM | Elements E1, E2, E3, ... previously added will be excluded. |
| PART | Elements of parts E1, E2, E3, ... will be included. |
| DPART | Elements of parts E1, E2, E3, ... previously added will be excluded. |
| BOX | Elements inside boxes E1, E2, E3, ... will be included. (see *DEFINE_BOX) |
| DBOX | Elements inside boxes E1, E2, E3, ... previously added will be excluded. |

*SET_BEAM_ADD

Purpose: Define a beam set by combining beam sets.

| | | | | | | | | |
|----------|------|---|---|---|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | SID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

Beam Element Set Cards. Each card can be used to specify up to 8 beam element sets. Include as many cards of this kind as necessary. This input ends at the next keyword ("**") card.

| | | | | | | | | |
|----------|-------|-------|-------|-------|-------|-------|-------|-------|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | BSID1 | BSID2 | BSID3 | BSID4 | BSID5 | BSID6 | BSID7 | BSID8 |
| Type | I | I | I | I | I | I | I | I |

VARIABLE

DESCRIPTION

SID Set ID of new beam set. All beam sets should have a unique set ID.

BSID[N] The Nth beam set ID on the card

*SET

*SET_BEAM_INTERSECT

*SET_BEAM_INTERSECT

Purpose: Define a beam set as the intersection, \cap , of a series of beam sets. The new beam set, SID, contains only the elements common to all beam sets listed on the cards of format 2.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | SID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

Beam Set Cards. Each card can be used to specify up to 8 beam sets. Include as many cards of this kind as necessary. This input ends at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

| Variable | BSID1 | BSID2 | BSID3 | BSID4 | BSID5 | BSID6 | BSID7 | BSID8 |
| Type | I | I | I | I | I | I | I | I |

VARIABLE

DESCRIPTION

| | |
|---------|--|
| SID | Set ID of new beam set. All beam sets should have a unique set ID. |
| BSID[N] | The N th beam set ID on card2 |

***SET_BOX**

Purpose: Define a set of boxes. See *DEFINE_BOX.

| | | | | | | | | |
|----------|------|---|---|---|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | SID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

Box Set Cards. Each card can be used to specify up to 8 box IDs. Include as many cards as desired. This input ends at the next keyword ("*") card.

| | | | | | | | | |
|----------|------|------|------|------|------|------|------|------|
| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | BID1 | BID2 | BID3 | BID4 | BID5 | BID6 | BID7 | BID8 |
| Type | I | I | I | I | I | I | I | I |

VARIABLE

DESCRIPTION

SID Set ID of new box set. All box sets should have a unique set ID.

BID[N] The Nth box ID

***SET_DISCRETE_{OPTION1}_{OPTION2}**

For *OPTION1* the available options are:

<BLANK>

GENERATE

GENERAL

For *OPTION2* the available option is:

COLLECT

The option GENERATE will generate a block of discrete element IDs between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the set.

Purpose: Define a set of discrete elements.

Card Summary:

Card 1. This card is required.

| | | | | | | | |
|-----|--|--|--|--|--|--|--|
| SID | | | | | | | |
|-----|--|--|--|--|--|--|--|

Card 2a. This card is included if and only if the keyword option is unset (<BLANK>). Include as many cards as needed. This input ends at the next keyword (“*”) card.

| | | | | | | | |
|----|----|----|----|----|----|----|----|
| K1 | K2 | K3 | K4 | K5 | K6 | K7 | K8 |
|----|----|----|----|----|----|----|----|

Card 2b. This card is included if and only if the GENERATE keyword option is used. Include as many cards as needed. This input ends at the next keyword (“*”) card.

| | | | | | | | |
|-------|-------|-------|-------|-------|-------|-------|-------|
| B1BEG | B1END | B2BEG | B2END | B3BEG | B3END | B4BEG | B4END |
|-------|-------|-------|-------|-------|-------|-------|-------|

Card 2c. This card is included if and only if the GENERAL keyword option is used. Include as many cards as needed. This input ends at the next keyword (“*”) card.

| | | | | | | | |
|--------|----|----|----|----|----|----|----|
| OPTION | E1 | E2 | E3 | E4 | E5 | E6 | E7 |

Data Card Definitions:

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | SID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

VARIABLE

DESCRIPTION

SID

Set ID

Discrete Element ID Cards. This card applies to the case of an unset (<BLANK>) keyword option. Set one value per element in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

| Card 2a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|----|----|----|----|----|----|
| Variable | K1 | K2 | K3 | K4 | K5 | K6 | K7 | K8 |
| Type | I | I | I | I | I | I | I | I |

VARIABLE

DESCRIPTION

K_i

i^{th} discrete element

Discrete Element Range Cards. This card applies to the GENERATE keyword option. Set one pair of BNBEQ and BNEND values per block of elements. Include as many cards as needed. This input ends at the next keyword ("*") card.

| Card 2b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|-------|-------|-------|-------|-------|
| Variable | B1BEG | B1END | B2BEG | B2END | B3BEG | B3END | B4BEG | B4END |
| Type | I | I | I | I | I | I | I | I |

VARIABLE

DESCRIPTION

B[N]BEG

First discrete element ID in block N.

| VARIABLE | DESCRIPTION |
|-----------------|--|
| B[N]END | Last discrete element ID in block N. All defined IDs between and including B[N]BEG to B[N]END are added to the set. These sets are generated after all input is read so that gaps in the element numbering are not a problem. B[N]BEG and B[N]END may simply be limits on the IDs and not element IDs. |

Generalized Discrete Element Range Cards. This card applies to the GENERAL keyword option. Include as many cards as needed. This input ends at the next keyword ("*") card.

| Card 2c | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|----|----|----|----|----|----|----|
| Variable | OPTION | E1 | E2 | E3 | E4 | E5 | E6 | E7 |
| Type | A | I | I | I | I | I | I | I |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| OPTION | Option for GENERAL. See table below. |
| E1, ..., E7 | Specified entity. Each card must have the option specified. See table below. |

The General Option:

The "OPTION" column in the table below enumerates the allowed values for the "OPTION" field in Card 2 for the GENERAL option. Likewise, the variables E1, ..., E7 refer to the GENERAL option Card 2.

Each of the following operations accept up to 7 arguments, but they may take fewer. Values of E_n left unspecified are ignored.

| OPTION | DESCRIPTION |
|---------------|---|
| ALL | All discrete elements will be included in the set. |
| ELEM | Elements E1, E2, E3, ... will be included. |
| DELEM | Elements E1, E2, E3, ... previously added will be excluded. |
| PART | Elements of parts E1, E2, E3, ... will be included. |

| OPTION | DESCRIPTION |
|---------------|---|
| DPART | Elements of parts E1, E2, E3, ... previously added will be excluded. |
| BOX | Elements inside boxes E1, E2, E3, ... will be included. (see *DEFINE_BOX) |
| DBOX | Elements inside boxes E1, E2, E3, ... previously added will be excluded. |

*SET

*SET_DISCRETE_ADD

*SET_DISCRETE_ADD

Purpose: Define a discrete set by combining discrete sets.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | SID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

Discrete Element Set Cards. Each card can be used to specify up to 8 discrete element sets. Include as many cards of this kind as necessary. This input ends at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|-------|-------|-------|-------|-------|
| Variable | DSID1 | DSID2 | DSID3 | DSID4 | DSID5 | DSID6 | DSID7 | DSID8 |
| Type | I | I | I | I | I | I | I | I |

VARIABLE

DESCRIPTION

SID Set ID of new discrete element set. All discrete element sets must have a unique ID.

DSID[N] The Nth discrete set ID on Card 2

*SET_MODE_{OPTION}

Available options include:

<BLANK>

LIST

LIST_GENERATE

The last option, LIST_GENERATE, will generate a block of mode IDs between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the set.

Purpose: Define a set of modes.

Card Summary:

Card 1. This card is required.

| | | | | | | | |
|-----|--|--|--|--|--|--|--|
| SID | | | | | | | |
|-----|--|--|--|--|--|--|--|

Card 2a. This card is included if and only if the keyword option is set to LIST or left unset. Include as many cards as needed. This input ends at the next keyword ("*") card.

| | | | | | | | |
|------|------|------|------|------|------|------|------|
| MID1 | MID2 | MID3 | MID4 | MID5 | MID6 | MID7 | MID8 |
|------|------|------|------|------|------|------|------|

Card 2b. This card is included if and only if the LIST_GENERATE keyword option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

| | | | | | | | |
|-------|-------|-------|-------|-------|-------|-------|-------|
| M1BEG | M1END | M2BEG | M2END | M3BEG | M3END | M4BEG | M4END |
|-------|-------|-------|-------|-------|-------|-------|-------|

Data Card Definitions:

| | | | | | | | | |
|----------|------|---|---|---|---|---|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | SID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

Mode ID Cards. This card is included when the keyword option is set to LIST *or* left unset (<BLANK>). Set one value per mode in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

| Card 2a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | MID1 | MID2 | MID3 | MID4 | MID5 | MID6 | MID7 | MID8 |
| Type | I | I | I | I | I | I | I | I |

Mode Range Cards. This card applies to the LIST_GENERATE keyword option. Set one pair of MNBEG and MNEND values per block of modes. Include as many cards as needed. This input ends at the next keyword ("*") card.

| Card 2b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|-------|-------|-------|-------|-------|
| Variable | M1BEG | M1END | M2BEG | M2END | M3BEG | M3END | M4BEG | M4END |
| Type | I | I | I | I | I | I | I | I |

VARIABLE**DESCRIPTION**

| | |
|---------|--|
| SID | Set identification. All mode sets should have a unique set ID. |
| MID[N] | Mode ID N. |
| M[N]BEG | First mode ID in block N. |
| M[N]END | Last mode ID in block N. All defined IDs between and including M[N]BEG and M[N]END are added to the set. |

Remarks:

The available mode IDs can be found in ASCII file eigout, or binary database d3eigv.

***SET_MULTI**

Note that this keyword’s name has been shortened. Its older long form, however, is still also valid.

***SET_MULTI-MATERIAL_GROUP_LIST**

Purpose: This command defines an ALE multi-material set ID (AMMSID) which contains a collection of one or more ALE multi-material group ID(s) (AMMGID). This provides a means for selecting any specific ALE multi-material(s). Applications include, for example, a selection of any particular fluid(s) to be coupled to a fluid-structure interaction.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|---|---|---|---|---|---|---|
| Variable | AMMSID | | | | | | | |
| Type | I | | | | | | | |
| Default | 0 | | | | | | | |

Multi-Material Group ID Cards. Set one value per element in the set. Include as many cards as needed. This input ends at the next keyword (“*”) card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---------|---------|---------|---------|---------|---------|---------|---------|
| Variable | AMMGID1 | AMMGID2 | AMMGID3 | AMMGID4 | AMMGID5 | AMMGID6 | AMMGID7 | AMMGID8 |
| Type | I | I | I | I | I | I | I | I |
| Default | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| AMMSID | An ALE multi-material set ID (AMMSID) which contains a collection of one or more ALE multi-material group ID(s) (AMMGID). |
| AMMGID1 | The 1 st ALE multi-material group ID. AMMGID1 references the input data line of the *ALE_MULTI-MATERIAL_GROUP card. |
| ⋮ | ⋮ |

***SET**

***SET_MULTI-MATERIAL_GROUP_LIST**

| VARIABLE | DESCRIPTION |
|-----------------|--|
| AMMGID8 | The 1 st ALE multi-material group ID. AMMGID8 references the input data line of the *ALE_MULTI-MATERIAL_GROUP card. |

Remarks:

Refer to an example in the *ALE_FSI_PROJECTION section.

*SET_NODE_{OPTION1}_{OPTION2}

For OPTION1 the available options are:

- <BLANK>
- LIST
- COLUMN
- LIST_GENERATE
- LIST_GENERATE_INCREMENT
- GENERAL
- LIST_SMOOTH

For OPTION2 the available option is:

COLLECT

The LIST option generates a set for a list of node IDs. The LIST_GENERATE and LIST_GENERATE_INCREMENT options will generate block(s) of node IDs between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the node set. The option LIST_SMOOTH is used to define a local region on a distorted tooling mesh to be smoothed. The LIST_SMOOTH option is documented in the [Local Smoothing of Tooling Mesh](#) section of the *INTERFACE_COMPENSATION_3D card's documentation. The COLUMN option is for setting nodal attributes, which pass data to other keyword cards, on a node-by-node basis.

Purpose: Define a nodal set with some identical or unique attributes.

Card Summary:

Card 1. This card is required.

| | | | | | | | |
|-----|-----|-----|-----|-----|--------|--|--|
| SID | DA1 | DA2 | DA3 | DA4 | SOLVER | | |
|-----|-----|-----|-----|-----|--------|--|--|

Card 2a. This card is included if and only if the keyword option is unset (<BLANK>), LIST, or LIST_SMOOTH. Include as many cards as needed. This input ends at the next keyword ("*") card.

| | | | | | | | |
|------|------|------|------|------|------|------|------|
| NID1 | NID2 | NID3 | NID4 | NID5 | NID6 | NID7 | NID8 |
|------|------|------|------|------|------|------|------|

Card 2b. This card is included if and only if the keyword option is COLUMN. Include one card per node in the set. This input ends at the next keyword ("*") card

| | | | | | | | |
|-----|----|----|----|----|--|--|--|
| NID | A1 | A2 | A3 | A4 | | | |
|-----|----|----|----|----|--|--|--|

Card 2c. This card is included if and only if the LIST_GENERATE keyword option is used. Set one pair of BNBEG and BNEND values per block of nodes. This input ends at the next keyword ("*") card

| | | | | | | | |
|-------|-------|-------|-------|-------|-------|-------|-------|
| B1BEG | B1END | B2BEG | B2END | B3BEG | B3END | B4BEG | B4END |
|-------|-------|-------|-------|-------|-------|-------|-------|

Card 2d. This card is included if and only if the LIST_GENERATE_INCREMENT keyword option is used. For each block of nodes add one card to the deck. This input ends at the next keyword ("*") card.

| | | | | | | | |
|------|------|------|--|--|--|--|--|
| BBEG | BEND | INCR | | | | | |
|------|------|------|--|--|--|--|--|

Card 2e. This card is included if and only if the GENERAL keyword option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

| | | | | | | | |
|--------|----|----|----|----|----|----|----|
| OPTION | E1 | E2 | E3 | E4 | E5 | E6 | E7 |

| Remark | | 2 | 2 | 2 | 2 | | | |

| VARIABLE | DESCRIPTION |
|----------|------------------------|
| NID | Nodal ID |
| A1 | First nodal attribute |
| A2 | Second nodal attribute |

| VARIABLE | DESCRIPTION |
|-----------------|------------------------|
| A3 | Third nodal attribute |
| A4 | Fourth nodal attribute |

Node ID Range Cards. This Card 2 format applies to the LIST_GENERATE keyword option. Set one pair of BNBEG and BNEND values per block of nodes. Include as many cards as needed. This input ends at the next keyword ("**") card.

| Card 2c | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|-------|-------|-------|-------|-------|
| Variable | B1BEG | B1END | B2BEG | B2END | B3BEG | B3END | B4BEG | B4END |
| Type | I | I | I | I | I | I | I | I |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| <i>BnBEG</i> | First node ID in block <i>n</i> . |
| <i>BnEND</i> | Last node ID in block <i>n</i> . All defined ID's between and including <i>BnBEG</i> to <i>BnEND</i> are added to the set. These sets are generated after all input is read so that gaps in the node numbering are not a problem. <i>BnBEG</i> and <i>BnEND</i> may simply be limits on the ID's and not nodal ID's. |

Node ID Range with Increment Cards. This Card 2 format applies to the LIST_GENERATE_INCREMENT keyword option. For each block of nodes add one card to the deck. This input ends at the next keyword ("**") card.

| Card 2d | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|---|---|---|---|---|
| Variable | BBEG | BEND | INCR | | | | | |
| Type | I | I | I | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| BBEG | First node ID in block. |
| BEND | Last node ID in block. |
| INCR | Node ID increment. Node IDs BBEG, BBEG + INCR, BBEG + 2 × INCR, and so on through BEND are added to the set. |

Generalized Node ID Range Cards. This Card 2 format applies to the GENERAL keyword option. Include as many cards as needed. This input ends at the next keyword ("**") card.

| Card 2e | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|----|----|----|----|----|----|----|
| Variable | OPTION | E1 | E2 | E3 | E4 | E5 | E6 | E7 |
| Type | A | I | I | I | I | I | I | I |

VARIABLE**DESCRIPTION**

OPTION

Option for GENERAL. See table below.

E1, ..., E7

Specified entity. Each card must have the option specified. See table below.

The General Option:

The "OPTION" column in the table below enumerates the allowed values for the "OPTION" variable in Card 2e for the GENERAL option. Likewise, the variables E1, ..., E7 refer to the GENERAL option Card 2e.

Each of the following operations accept up to 7 arguments, but they may take fewer. Values of "En" left unspecified are ignored.

OPTION**DESCRIPTION**

ALL

All nodes will be included in the set.

NODE

Nodes E1, E2, E3, ... will be included.

DNODE

Nodes E1, E2, E3, ... previously added will be excluded.

PART

Nodes of parts E1, E2, E3, ... will be included.

DPART

Nodes of parts E1, E2, E3, ... previously added will be excluded.

BOX

Nodes inside boxes E1, E2, E3, ... will be included. (see *DEFINE_BOX)

DBOX

Nodes inside boxes E1, E2, E3, ... previously added will be excluded.

| OPTION | DESCRIPTION |
|---------------|---|
| VOL | Nodes inside contact volumes E1, E2, E3, ... will be included. (see *DEFINE_CONTACT_VOLUME) |
| DVOL | Nodes inside contact volumes E1, E2, E3, ... previously added will be excluded. |
| SET_XXXX | Include nodal points of element sets defined by SET_XXXX_LIST, where XXXX could be SHELL, SOLID, BEAM, TSHELL and SPRING |
| SALECPT | Nodes inside a box in a Structured ALE mesh. E1 here is the S-ALE mesh ID (MSHID). E2, E3, E4, E5, E6, E7 correspond to XMIN, XMAX, YMIN, YMAX, ZMIN, ZMAX. They are the minimum and the maximum nodal indices along each direction in S-ALE mesh. This option is only to be used for Structured ALE mesh and should not be used in a mixed manner with other "_GENERAL" options. Please refer to *ALE_STRUCTURED_MESH_CONTROL_POINTS and *ALE_STRUCTURED_MESH_CONTROL for more details. |
| SALEFAC | Nodes that are on the face of a Structured ALE mesh. E1 gives the S-ALE mesh ID (MSHID). E2, E3, E4, E5, E6, E7 correspond to -x, +x, -y, +y, -z, +z faces. Assigning 1, for instance, to these 6 values would include all the surface segments at these faces in the segment set. This option is only to be used for Structured ALE mesh and should not be used in a mixed manner with other "_GENERAL" options. Please refer to *ALE_STRUCTURED_MESH_CONTROL_POINTS and *ALE_STRUCTURED_MESH_CONTROL for more details. |

Remarks:

1. **Nodal Attributes.** Nodal attributes can be assigned to pass data to other keywords. For example, for contact option, *CONTACT_TIEBREAK_NODES_TO_SURFACE the attributes are:

DA1 = NFLF ⇒ Normal failure force,

DA2 = NSFL ⇒ Shear failure force,

DA3 = NNEN ⇒ Exponent for normal force,

DA4 = NMES ⇒ Exponent for shear force.

2. **Overriding Nodal Attributes.** The nodal attributes set in Card 1 can be overridden on a node by node basis by using the COLUMN keyword option. Card 2b for this keyword option allows the user to set the attributes for each node. If left unset on Card 2b, the values default to those set in Card 1, that is, A1 = DA1, etc.
3. **Solvers.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.
4. **LIST_SMOOTH Option.** The option *SET_NODE_LIST_SMOOTH is used for localized tooling surface smoothing, and it is used in conjunction with keywords *INTERFACE_COMPENSATION_NEW_LOCAL_SMOOTH, *INCLUDE_COMPENSATION_ORIGINAL_RIGID_TOOL, and *INCLUDE_COMPENSATION_NEW_RIGID_TOOL. This option is available in R6 Revision 73850 and later releases.

<BLANK>

ADVANCED

Purpose: Define a node set by combining node sets or for the ADVANCED option by combining, NODE, SHELL, SOLID, BEAM, SEGMENT, DISCRETE and THICK SHELL sets.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|--------|---|---|
| Variable | NSID | DA1 | DA2 | DA3 | DA4 | SOLVER | | |
| Type | I | F | F | F | F | A | | |
| Default | none | none | none | none | none | MECH | | |

Node Set Cards. This card is included when the keyword option is left unset (<BLANK>). Each card can be used to specify up to 8 node set IDs. Include as many cards of this kind as necessary. This input ends at the next keyword ("*") card.

| Card 2a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|-------|-------|-------|-------|-------|
| Variable | NSID1 | NSID2 | NSID3 | NSID4 | NSID5 | NSID6 | NSID7 | NSID8 |
| Type | I | I | I | I | I | I | I | I |

Node Set Advanced Cards. This card is included when the keyword option is set to ADVANCED. Each card can be used to specify up to 4 set IDs (node sets, beam sets, etc...). Include as many cards of this kind as necessary. This input ends at the next keyword ("*") card.

| Card 2b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|------|-------|------|-------|------|-------|
| Variable | SID1 | TYPE1 | SID2 | TYPE2 | SID3 | TYPE3 | SID4 | TYPE4 |
| Type | I | I | I | I | I | I | I | I |

| VARIABLE | DESCRIPTION |
|----------|---|
| NSID | Set ID of new node set. All node sets should have a unique set ID. |
| DA1 | First nodal attribute default value; see Remark 1 below. |
| DA2 | Second nodal attribute default value |
| DA3 | Third nodal attribute default value |
| DA4 | Fourth nodal attribute default value |
| SOLVER | Name of solver using this set (MECH, CESE, etc.). See Remark 1 . |
| NSID[N] | The N th node set ID on Card 2a. |
| SID[N] | The N th set ID on Card 2b. |
| TYPE[N] | Type of set for SID[N]: EQ.1: Node set EQ.2: Shell set EQ.3: Beam set EQ.4: Solid set EQ.5: Segment set EQ.6: Discrete set EQ.7: Thick shell set |

Remarks:

1. **Solvers and Mesh.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

***SET_NODE_INTERSECT**

Purpose: Define a node set as the intersection, \cap , of a series of node sets. The new node set, NSID, contains all common elements of all node sets listed on all cards in format 2.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|-----|-----|-----|--------|---|---|
| Variable | SID | DA1 | DA2 | DA3 | DA4 | SOLVER | | |
| Type | I | F | F | F | F | A | | |
| Default | none | 0. | 0. | 0. | 0. | MECH | | |
| Remarks | | | | | | 1 | | |

Node Set Cards. For each SID in the intersection specify one field. Include as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|-------|-------|-------|-------|-------|
| Variable | NSID1 | NSID2 | NSID3 | NSID4 | NSID5 | NSID6 | NSID7 | NSID8 |
| Type | I | I | I | I | I | I | I | I |

VARIABLE**DESCRIPTION**

| | |
|------------------------|--|
| SID | Set ID of new node set. All node sets should have a unique set ID. |
| DA _{<i>i</i>} | <i>i</i> th nodal attribute |
| SOLVER | Name of solver using this set (MECH, CESE, etc.) |
| NSID[N] | The N th node set ID. |

Remarks:

1. **Solver.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

*SET_PART_{OPTION1}_{OPTION2}

For OPTION1 available options are:

- <BLANK>
- LIST
- COLUMN
- LIST_GENERATE
- LIST_GENERATE_INCREMENT

For OPTION2 the available option is:

COLLECT

The LIST_GENERATE and LIST_GENERATE_INCREMENT options will generate block(s) of part IDs between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the part set.

Purpose: Define a set of parts with optional attributes. For the COLUMN option, see *AIRBAG or *CONSTRAINED_RIGID_BODY_STOPPERS.

Card Summary:

Card 1. This card is required.

| | | | | | | | |
|-----|-----|-----|-----|-----|--------|--|--|
| SID | DA1 | DA2 | DA3 | DA4 | SOLVER | | |
|-----|-----|-----|-----|-----|--------|--|--|

Card 2a. This card is included if and only if the keyword option is left unset or is LIST. Include as many cards as needed. This input ends at the next keyword ("*") card.

| | | | | | | | |
|------|------|------|------|------|------|------|------|
| PID1 | PID2 | PID3 | PID4 | PID5 | PID6 | PID7 | PID8 |
|------|------|------|------|------|------|------|------|

Card 2b. This card is included if and only if the COLUMN keyword option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

| | | | | | | | |
|-----|----|----|----|----|--|--|--|
| PID | A1 | A2 | A3 | A4 | | | |
|-----|----|----|----|----|--|--|--|

Card 2c. This card is included if and only if the GENERATE keyword option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

| | | | | | | | |
|-------|-------|-------|-------|-------|-------|-------|-------|
| B1BEG | B1END | B2BEG | B2END | B3BEG | B3END | B4BEG | B4END |
|-------|-------|-------|-------|-------|-------|-------|-------|

Card 2d. This card is included if and only if the LIST_GENERATE_INCREMENT keyword option is used. Include as many cards as needed. This input ends at the next keyword ("*") card.

| | | | | | | | | |
|-----|------|------|--|--|--|--|--|--|
| BEG | BEND | INCR | | | | | | |
|-----|------|------|--|--|--|--|--|--|

Data Cards:

| | | | | | | | | |
|----------|------|-----|-----|-----|-----|--------|---|---|
| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | SID | DA1 | DA2 | DA3 | DA4 | SOLVER | | |
| Type | I | F | F | F | F | A | | |
| Default | none | 0. | 0. | 0. | 0. | MECH | | |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| SID | Set ID. All part sets should have a unique set ID. |
| DA1 | First attribute default value; see Remark 1 . |
| DA2 | Second attribute default value |
| DA3 | Third attribute default value |
| DA4 | Fourth attribute default value |
| SOLVER | Name of solver using this set (MECH, CESE, etc.). See Remark 3 . |

Part ID Cards. This Card 2 format applies to the LIST keyword option and the unset (<BLANK>) keyword option. Set one value per part in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

| | | | | | | | | |
|----------|------|------|------|------|------|------|------|------|
| Card 2a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | PID1 | PID2 | PID3 | PID4 | PID5 | PID6 | PID7 | PID8 |
| Type | I | I | I | I | I | I | I | I |

| <u>VARIABLE</u> | <u>DESCRIPTION</u> |
|-------------------------|--------------------------------|
| PID _{<i>i</i>} | <i>i</i> th part ID |

Part ID with Column Cards. This Card 2 format applies to the COLUMN keyword option. Include one card per part in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

| Card 2b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|----|----|----|----|---|---|---|
| Variable | PID | A1 | A2 | A3 | A4 | | | |
| Type | I | F | F | F | F | | | |
| Remark | | 2 | 2 | 2 | 2 | | | |

| <u>VARIABLE</u> | <u>DESCRIPTION</u> |
|-----------------|-----------------------|
| PID | Part ID |
| A1 | First part attribute |
| A2 | Second part attribute |
| A3 | Third part attribute |
| A4 | Fourth part attribute |

Part ID Range Cards. This Card 2 format applies to the GENERATE keyword option. Set one pair of BNBEG and BNEND values per block of part IDs. Include as many cards as needed. This input ends at the next keyword ("*") card.

| Card 2c | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|-------|-------|-------|-------|-------|
| Variable | B1BEG | B1END | B2BEG | B2END | B3BEG | B3END | B4BEG | B4END |
| Type | I | I | I | I | I | I | I | I |

| <u>VARIABLE</u> | <u>DESCRIPTION</u> |
|-----------------|---------------------------|
| B[N]BEG | First part ID in block N. |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| B[N]END | Last part ID in block N. All defined ID's between and including B[N]BEG to B[N]END are added to the set. These sets are generated after all input is read so that gaps in the part numbering are not a problem. B[N]BEG and B[N]END may simply be limits on the ID's and not part ID's. |

Part ID Range with Increment Cards. This Card 2 format applies to the LIST_GENERATE_INCREMENT keyword option. For each block of parts add one card to the deck. This input ends at the next keyword ("*") card.

| Card 2d | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|---|---|---|---|---|
| Variable | BBEG | BEND | INCR | | | | | |
| Type | I | I | I | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| BBEG | First part ID in block. |
| BEND | Last part ID in block. |
| INCR | Part ID increment. Part IDs BBEG, BBEG+INCR, BBEG + 2 × INCR, and so on through BEND are added to the set. |

Remarks:

1. **Part Attributes.** Part attributes can be assigned for some input types. For example, for airbags a time delay, DA1 = T1, can be defined before pressure begins to act along with a time delay, DA2 = T2, before full pressure is applied (default T2 = T1). For *CONSTRAINED_RIGID_BODY_STOPPERS one attribute can be defined: DA1 as the closure distance which activates the stopper constraint.
2. **Individual Part Attributes.** The default part attributes can be overridden on the part cards with the COLUMN keyword option; otherwise, A1 = DA1, etc.
3. **Solvers.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

***SET_PART_ADD**

Purpose: Define a part set by combining part sets.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|--------|---|---|
| Variable | SID | DA1 | DA2 | DA3 | DA4 | SOLVER | | |
| Type | I | F | F | F | F | A | | |
| Default | none | 0.0 | 0.0 | 0.0 | 0.0 | MECH | | |
| Remarks | | 1, 2 | 1, 2 | 1, 2 | 1, 2 | 3 | | |

Part Set Cards. Each card can be used to specify up to 8 part set IDs. Include as many cards of this kind as necessary. This input ends at the next keyword ("*") card.

| Card 2... | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-----------|-------|-------|-------|-------|-------|-------|-------|-------|
| Variable | PSID1 | PSID2 | PSID3 | PSID4 | PSID5 | PSID6 | PSID7 | PSID8 |
| Type | I | I | I | I | I | I | I | I |

VARIABLE**DESCRIPTION**

| | |
|--------|--|
| SID | Set ID. All part sets should have a unique set ID. |
| DA1 | First attribute default value |
| DA2 | Second attribute default value |
| DA3 | Third attribute default value |
| DA4 | Fourth attribute default value |
| SOLVER | Name of solver using this set (MECH, CESE, etc.) |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| PSID[N] | The N th part set ID GT.0: PSID[N] is added to SID, LT.0: all part sets with ID between PSID[N-1] and -PSID[N], including PSID[N-1] and -PSID[N], will be added to SID. PSID[N-1] must be > 0 and must have a magnitude smaller or equal to -PSID[N] when PSID[N] < 0. |

Remarks:

- Part Attributes.** Part attributes can be assigned for some input types. For example, for airbags a time delay, DA1 = T1, can be defined before pressure begins to act along with a time delay, DA2 = T2, before full pressure is applied, (default T2 = T1). For the constraint option, *CONSTRAINED_RIGID_BODY_STOPPERS one attribute can be defined: DA1, the closure distance which activates the stopper constraint.
- Overriding Part Attributes.** The default values for the part attributes are given in the contributing *SET_PART_{OPTION} commands. Nonzero values of DA1, DA2, DA3, or DA4 in *SET_PART_ADD will override the respective default values.
- Solver.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

*SET_SEGMENT_{OPTION1}_{OPTION2}

For OPTION1 the available options are:

<BLANK>

GENERAL

For OPTION2 the available option is

COLLECT

Purpose: Define a set of segments with optional identical or unique attributes. For three-dimensional geometries, a segment can be triangular or quadrilateral. For two-dimensional geometries, a segment is a line defined by two nodes and the GENERAL option does not apply.

Card Summary:

Card 1. This card is required.

| | | | | | | | |
|-----|-----|-----|-----|-----|--------|--|--|
| SID | DA1 | DA2 | DA3 | DA4 | SOLVER | | |
|-----|-----|-----|-----|-----|--------|--|--|

Card 2a. This card is included if and only if OPTION1 is <BLANK>. Include as many cards as necessary. This input ends at the next keyword ("*") card.

| | | | | | | | |
|----|----|----|----|----|----|----|----|
| N1 | N2 | N3 | N4 | A1 | A2 | A3 | A4 |
|----|----|----|----|----|----|----|----|

Card 2b. This card is included if and only if OPTION1 is GENERAL. Include as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| Variable | SID | DA1 | DA2 | DA3 | DA4 | SOLVER | | |
| Type | I | F | F | F | F | A | | |
| Default | none | 0. | 0. | 0. | 0. | MECH | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| SID | Set ID. All segment sets should have a unique set ID. |
| DA1 | First segment attribute default value. See Remark 1 . |
| DA2 | Second segment attribute default value. See Remark 1 . |
| DA3 | Third segment attribute default value. See Remark 1 . |
| DA4 | Fourth segment attribute default value. See Remark 1 . |
| SOLVER | Name of solver using this set (MECH, CESE, etc.). See Remark 3 . |

Segment Cards. For each segment in the set include one card of this format unless the GENERAL option is used. Include as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 2a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|----|----|----|----|----|----|
| Variable | N1 | N2 | N3 | N4 | A1 | A2 | A3 | A4 |
| Type | I | I | I | I | F | F | F | F |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| N1 | Nodal point n_1 |
| N2 | Nodal point n_2 |
| N3 | Nodal point n_3 |
| N4 | Nodal point n_4 . To define a triangular segment, set $N4 = N3$. |
| A1 | First segment attribute. See Remark 2 . |
| A2 | Second segment attribute. See Remark 2 . |
| A3 | Third segment attribute. See Remark 2 . |
| A4 | Fourth segment attribute. See Remark 2 . |

Generalized Part ID Range Cards. This Card 2 format applies to the GENERAL keyword option. Include as many cards as needed. This input ends at the next keyword (“**”) card.

| Card 2b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|----|----|----|--------|--------|--------|--------|
| Variable | OPTION | E1 | E2 | E3 | E4 | E5 | E6 | E7 |
| Type | A | I | I | I | I or F | I or F | I or F | I or F |

VARIABLE**DESCRIPTION**

OPTION

Option for GENERAL. See table below.

E1, ..., E7

Specified entity. Each card must have an option specified. See table below.

The General Option:

The “OPTION” column in the table below enumerates the allowed values for the “OPTION” variable in Card 2 for the GENERAL option. Likewise, the variables E1, ..., E7 refer to the GENERAL option Card 2.

Each of the following operations accept up to 7 arguments, but they may take fewer. Values of “En” left unspecified are ignored.

OPTION**DESCRIPTION**

ALL

All exterior segments will be included in the set.

BOX

Generate segments inside boxes having IDs E1, E2, and E3 with attributes having values E4, E5, E6, and E7. For shell elements one segment per shell is generated. For solid elements only those segments wrapping the solid part and pointing outward from the part will be generated.

BOX_SHELL

Generate segments inside boxes having IDs E1, E2, and E3 with attributes having values E4, E5, E6, and E7. The segments are only generated for shell elements. One segment per shell is generated.

BOX_SLDIO

Generate segments inside boxes having IDs E1, E2, and E3 with attributes having values E4, E5, E6, and E7. Both exterior segments and inter-element segments are generated.

| OPTION | DESCRIPTION |
|---------------|--|
| BOX_SOLID | Generate segments inside boxes having IDs E1, E2, and E3 with attributes having values E4, E5, E6, and E7. The segments are only generated for exterior solid elements |
| PART | Generate segments of parts E1, E2, and E3 with attributes E4, E5, E6, and E7. For shell elements one segment per shell is generated. For solid elements only those segments wrapping the solid part and pointing outward from the part will be generated. PART could refer to beam parts when defining 2D segments for traction application. |
| PART_IO | Generate segments from parts E1, E2, E3 with attributes E4, E5, E6, and E7. Same as the PART option above except that inter-element segments inside parts will be generated as well. This option is sometimes useful for single surface contact of solid elements to prevent negative volumes. |
| PSLDF i | Generate segments from the i th face of solid parts E1, E2, E3 with attributes E4, E5, E6, and E7. See Table 39-1 below for face definition. |
| SEG | Create segment with node IDs E1, E2, E3, and E4. |
| VOL | Generate segments inside contact volume IDs E1, E2, and E3 with attributes having values E4, E5, E6, and E7. See BOX option for other details. |
| VOL_SHELL | Generate segments for shells inside contact volume IDs E1, E2, and E3 with attributes having values E4, E5, E6, and E7 |
| VOL_SLDIO | Generate segments for solid elements inside contact volume IDs E1, E2, and E3 with attributes E4, E5, E6, and E7. See BOX_SLDIO for other details. |
| VOL_SOLID | Generate segments for solid elements inside contact volume IDs E1, E2, and E3 with attributes E4, E5, E6, and E7. See BOX_SOLID for other details. |
| SET_SHELL | Generate segments for shell elements in SET_SHELL_LIST with IDs E1, E2, and E3 with attributes E4, E5, E6, and E7. |
| SET_SOLID | Generate segments for solid elements in SET_SOLID_LIST with IDs E1, E2, and E3 with attributes E4, E5, E6, and E7. |

| OPTION | DESCRIPTION |
|---------------|--|
| SET_SLDIO | Generate segments for solid elements in SET_SOLID_LIST with IDs E1, E2, and E3 with attributes E4, E5, E6, and E7. Both exterior & interior segments are generated. |
| SET_SLDF i | Generate segments from the i th face of solid elements in SET_SOLID_LIST with IDs E1, E2, and E3 with attributes E4, E5, E6, and E7. See Table 39-1 below for face definition. |
| SET_TSHELL | Generate segments for thick shell elements in SET_TSHELL_LIST with IDs of E1, E2, and E3 with attributes E4, E5, E6, and E7. Only exterior segments are generated. |
| SET_TSHIO | Generate segments for thick shell elements in SET_TSHELL_LIST with IDs of E1, E2, and E3 with attributes E5, E5, E6, and E7. Both exterior & interior segments are generated. |
| DBOX | Segments inside boxes with IDs E1, ..., E7 will be excluded. |
| DBOX_SHELL | Shell related segments inside boxes of IDs E1, ..., E7 will be excluded. |
| DBOX_SOLID | Solid related segments inside boxes of IDs E1, ..., E7 will be excluded. |
| DPART | Segments of parts with IDs E1, ..., E7 will be excluded. |
| DSEG | Segment with node IDs E1, E2, E3, and E4 will be deleted. |
| DVOL | Segments inside contact volumes having IDs E1, ..., E7 will be excluded. |
| DVOL_SHELL | Shell related segments inside contact volumes having IDs E1, ..., E7 will be excluded. |
| DVOL_SOLID | Solid related segments inside contact volumes having IDs E1, ..., E7 will be excluded. |
| SALECPT | Segments inside a box in a Structured ALE mesh. E1 here is the S-ALE mesh ID (MSHID). E2, E3, E4, E5, E6, E7 correspond to XMIN, XMAX, YMIN, YMAX, ZMIN, ZMAX. They are the minimum and the maximum nodal indices along each direction in the S-ALE mesh. This option is only to be used for Structured ALE mesh and should not be used in a mixed manner with other “_GENERAL” options. |

| OPTION | DESCRIPTION |
|---------------|---|
| | Please refer to *ALE_STRUCTURED_MESH_CONTROL_POINTS and *ALE_STRUCTURED_MESH_CONTROL for more details. |
| SALEFAC | <p>Segments on the face of Structured ALE mesh. E1 here is the S-ALE mesh ID (MSHID). E2, E3, E4, E5, E6, E7 correspond to -X, +X, -Y, +Y, -Z, +Z faces. Assigning 1 to these 6 values would include all the surface segments at these faces in the segment set. This option is only to be used for Structured ALE mesh and should not be used in a mixed manner with other “_GENERAL” options.</p> <p>Please refer to *ALE_STRUCTURED_MESH_CONTROL_POINTS and *ALE_STRUCTURED_MESH_CONTROL for more details.</p> |

Remarks:

1. **Segment Attributes.** Segment attributes can be assigned for some input types. For example, for the contact options:

The attributes for the SLAVE surface are:

DA1 (NFLS) = Normal failure stress, *CONTACT_TIEBREAK_SURFACE contact only,

DA2 (SFSL) = Shear failure stress, *CONTACT_TIEBREAK_SURFACE contact only,

DA3 (FSF) = Coulomb friction scale factor,

DA4 (VSF) = Viscous friction scale factor,

and the attributes for the MASTER surface are:

DA3 (FSF) = Coulomb friction scale factor,

DA4 (VSF) = Viscous friction scale factor.

For airbags, see *AIRBAG, a time delay, DA1 = T1, can be defined before pressure begins to act on a segment along with a time delay, DA2 = T2, before full pressure is applied to the segment, (default T2 = T1), and for the constraint option,

2. **Setting Individual Attributes.** The default segment attributes can be overridden on Card 2a; otherwise, A1 = DA1, A2 = DA2, etc.

3. **Solvers.** The SOLVER field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

| FACE | Hexahedron | Pentahedron | Tetrahedron |
|------|----------------|----------------|-------------|
| 1 | N1, N5, N8, N4 | N1, N2, N5 | N1, N2, N4 |
| 2 | N2, N3, N7, N6 | N4, N6, N3 | N2, N3, N4 |
| 3 | N1, N2, N6, N5 | N1, N4, N3, N2 | N1, N3, N2 |
| 4 | N4, N8, N7, N3 | N2, N3, N6, N5 | N1, N4, N3 |
| 5 | N1, N4, N3, N2 | N1, N5, N6, N4 | |
| 6 | N5, N6, N7, N8 | | |

Table 39-1. Face definition of solid elements

*SET

*SET_SEGMENT_ADD

*SET_SEGMENT_ADD

Purpose: Define a segment set by combining segment sets.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|---|---|---|---|---|---|
| Variable | SID | SOLVER | | | | | | |

VARIABLE

DESCRIPTION

SID Set ID of new segment set. All segment sets should have a unique set ID.

SOLVER Name of solver using this set (MECH, CESE, etc.)

SSID[N] The Nth segment set ID.

Remarks:

1. **Solver.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

***SET_SEGMENT_INTERSECT**

Purpose: Define a segment set as the intersection, \cap , of a series of segment sets. The new segment set, SID, contains all segments common to the sets listed on all of the cards in format 2.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|---|---|---|---|---|---|
| Variable | SID | SOLVER | | | | | | |
| Type | I | A | | | | | | |
| Default | none | MECH | | | | | | |
| Remarks | | 1 | | | | | | |

Segment Set Cards. For each SID in the intersection specify one field. Include as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

VARIABLE**DESCRIPTION**

| | |
|---------|--|
| SID | Set ID of new segment set. All segment sets should have a unique set ID. |
| SOLVER | Name of solver using this set (MECH, CESE, etc.) |
| SSID[N] | The N th segment set ID |

Remarks:

1. **Solver.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

*SET

*SET_2D_SEGMENT

*SET_2D_SEGMENT_{OPTION1}_{OPTION2}

For *OPTION1* the available options are:

<BLANK>

SET

For *OPTION2* the available option is:

COLLECT

Purpose: Define a set of boundary line segments in two-dimensional axisymmetric, plane stress, and plane strain geometries with optional attributes. This command does not apply to beam formulations 7 and 8. This feature is sometimes convenient for two-dimensional parts that are subject to adaptivity because the segments in the set are updated as the geometry adapts.

Card Sets. For each set include a pair of Cards 1 and 2. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|-----|-----|-----|---|---|---|
| Variable | SID | DA1 | DA2 | DA3 | DA4 | | | |
| Type | I | F | F | F | F | | | |
| Default | none | 0. | 0. | 0. | 0. | | | |
| Remarks | | 1 | 1 | 1 | 1 | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|---|---|---|---|---|---|---|
| Variable | PID/PSID | | | | | | | |
| Type | I | | | | | | | |
| Remarks | 2 | | | | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| SID | Set ID. All segment sets should have a unique set ID. |
| DA1 | First segment attribute default value, see Remark 1 below. |
| DA2 | Second segment attribute default value |
| DA3 | Third segment attribute default value |
| DA4 | Fourth segment attribute default value |
| PID/PSID | Part ID or part set ID if SET option is specified. |

Remarks:

1. **Axisymmetric Problems.** The boundary along $r = 0$ is not included in axisymmetric problems.
2. **Common Boundary in Part Sets.** The common boundary between parts in the part set PSID is not included in the boundary segments.

***SET_SHELL_{OPTION1}_{OPTION2}**

For *OPTION1* the available options are:

<BLANK>

LIST

COLUMN

LIST_GENERATE

LIST_GENERATE_INCREMENT

GENERAL

For *OPTION2* the available option is:

COLLECT

The LIST_GENERATE and LIST_GENERATE_INCREMENT options will generate block(s) of shell element IDs between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the shell element set.

Purpose: Define a set of shell elements with optional identical or unique attributes.

Card Summary:

Card 1. This card is required.

| | | | | | | | |
|-----|-----|-----|-----|-----|--|--|--|
| SID | DA1 | DA2 | DA3 | DA4 | | | |
|-----|-----|-----|-----|-----|--|--|--|

Card 2a. This card is included if and only if the keyword option is unused or if the LIST keyword option is used. Set one value per element in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

| | | | | | | | |
|------|------|------|------|------|------|------|------|
| EID1 | EID2 | EID3 | EID4 | EID5 | EID6 | EID7 | EID8 |

VARIABLE

DESCRIPTION

- SID Set ID. All shell sets should have a unique set ID.
- DA1 First attribute default value
- DA2 Second attribute default value
- DA3 Third attribute default value
- DA4 Fourth attribute default value

Shell Element ID Cards. This Card 2 format applies to LIST keyword option. Additionally, it applies to the case of an unset (<blank>) keyword option. Set one value per element in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

| Card 2a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | EID1 | EID2 | EID3 | EID4 | EID5 | EID6 | EID7 | EID8 |
| Type | I | I | I | I | I | I | I | I |

VARIABLE**DESCRIPTION**

EID i i^{th} shell element ID

Shell Element ID with Column Cards. This Card 2 format applies to the COLUMN keyword option. Include one card per shell element in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

| Card 2b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|----|----|----|----|---|---|---|
| Variable | EID | A1 | A2 | A3 | A4 | | | |
| Type | I | F | F | F | F | | | |
| Remarks | | 2 | 2 | 2 | 2 | | | |

VARIABLE**DESCRIPTION**

EID Element ID
 A1 First attribute
 A2 Second attribute
 A3 Third attribute
 A4 Fourth attribute

Shell Element ID Range Cards. This Card 2 format applies to the GENERATE keyword option. Set one pair of BNBEQ and BNEND values per block of shell element IDs. Include as many cards as needed. This input ends at the next keyword ("*") card.

| Card 2c | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|-------|-------|-------|-------|-------|
| Variable | B1BEG | B1END | B2BEG | B2END | B3BEG | B3END | B4BEG | B4END |
| Type | I | I | I | I | I | I | I | I |

VARIABLE**DESCRIPTION**

B[N]BEG

First shell ID in shell block N.

B[N]END

Last shell ID in block N. All defined ID's between and including B[N]BEG to B[N]END are added to the set. These sets are generated after all input is read so that gaps in the element numbering are not a problem. B[N]BEG and B[N]END may simply be limits on the ID's and not element IDs.

Shell Element ID Range with Increment Cards. This Card 2 format applies to the LIST_GENERATE_INCREMENT keyword option. For each block of shell elements add one card to the deck. This input ends at the next keyword ("*") card.

| Card 2d | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|---|---|---|---|---|
| Variable | BBEG | BEND | INCR | | | | | |
| Type | I | I | I | | | | | |

VARIABLE**DESCRIPTION**

BBEG

First shell element ID in block.

BEND

Last shell element ID in block.

INCR

Shell element ID increment. Shell element IDs BBEG, BBEG + INCR, BBEG + 2 × INCR, and so on through BEND are added to the set.

Generalized Shell Element ID Range Cards. This Card 2 format applies to the GENERAL keyword option. Include as many cards as needed. This input ends at the next keyword (“*”) card.

| Card 2e | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|----|----|----|----|----|----|----|
| Variable | OPTION | E1 | E2 | E3 | E4 | E5 | E6 | E7 |
| Type | A | I | I | I | I | I | I | I |

VARIABLE**DESCRIPTION**

| | |
|-------------|--|
| OPTION | Option for GENERAL. See table below. |
| E1, ..., E7 | Specified entity. Each card must have the option specified. See table below. |

The General Option:

The “OPTION” column in the table below enumerates the allowed values for the “OPTION” variable in Card 2 for the GENERAL option. Likewise, the variables E1, ..., E7 refer to the GENERAL option Card 2.

Each of the following operations accept up to 7 arguments, but they may take fewer. Values of “En” left unspecified are ignored.

OPTION**DESCRIPTION**

| | |
|-------|---|
| ALL | All shell elements will be included in the set. |
| ELEM | Shell elements E1, E2, E3, ... will be included. |
| DELEM | Shell elements E1, E2, E3, ... previously added will be excluded. |
| PART | Shell elements of parts E1, E2, E3, ... will be included. |
| DPART | Shell elements of parts E1, E2, E3, ... previously added will be excluded. |
| BOX | Shell elements inside boxes E1, E2, E3, ... will be included. (see *DEFINE_BOX) |
| DBOX | Shell elements inside boxes E1, E2, E3, ... previously added will be excluded. |

Remarks:

1. **Shell Attributes.** Shell attributes can be assigned for some input types.

For example, for contact options, the attributes for the SLAVE surface are:

DA1 (NFLS) = Normal failure stress, *CONTACT_TIEBREAK_SURFACE
contact only,

DA2 (SFLS) = Shear failure stress, *CONTACT_TIEBREAK_SURFACE
contact only,

DA3 (FSF) = Coulomb friction scale factor,

DA4 (VSF) = Viscous friction scale factor,

and the attributes for the MASTER surface are:

DA1 (FSF) = Coulomb friction scale factor,

DA2 (VSF) = Viscous friction scale factor.

2. **Overriding Shell Attributes.** The default shell attributes for the set can be overridden for individual elements using Card 2b; otherwise, A1 = DA1, etc.

*SET

*SET_SHELL_ADD

*SET_SHELL_ADD

Purpose: Define a shell set by combining shell sets.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | SID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

Shell Element Set Cards. Each card can be used to specify up to 8 shell element set IDs. Include as many cards as necessary. This input ends at the next keyword (“*”) card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

VARIABLE

DESCRIPTION

SID Set ID of new shell set. All shell sets should have a unique set ID.

SSID[N] The Nth shell set ID

***SET_SOLID**_{OPTION1}_{OPTION2} For *OPTION1* the available options are:

<BLANK>

GENERATE

GENERATE_INCREMENT

GENERAL

For *OPTION2* the available option is:

COLLECT

The GENERATE and GENERATE_INCREMENT options will generate block(s) of solid element IDs between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the solid element set.

Purpose: Define a set of solid elements.

Card Summary:

Card 1. This card is required.

| | | | | | | | |
|-----|--------|--|--|--|--|--|--|
| SID | SOLVER | | | | | | |
|-----|--------|--|--|--|--|--|--|

Card 2a. This card is included if and only if the keyword option is left unset (<BLANK>). Set one value per solid element in the set. Include as many cards as needed. This input ends at the next keyword ("*") card.

| | | | | | | | |
|----|----|----|----|----|----|----|----|
| K1 | K2 | K3 | K4 | K5 | K6 | K7 | K8 |
|----|----|----|----|----|----|----|----|

Card 2b. This card is included if and only if the keyword option GENERATE is used. Set one pair of BNBEG and BNEND values per block of solid elements. Include as many cards as needed. This input ends at the next keyword ("*") card.

| | | | | | | | |
|-------|-------|-------|-------|-------|-------|-------|-------|
| B1BEG | B1END | B2BEG | B2END | B3BEG | B3END | B4BEG | B4END |
|-------|-------|-------|-------|-------|-------|-------|-------|

Card 2c. This card is included if and only if the keyword option GENERATE_INCREMENT is used. For each block of solid elements add one card to the deck. This input ends at the next keyword ("*") card.

| | | | | | | | |
|------|------|------|--|--|--|--|--|
| BBEG | BEND | INCR | | | | | |
|------|------|------|--|--|--|--|--|

Card 2d. This card is included if and only if the keyword option GENERAL is used. Include as many cards as needed. This input ends at the next keyword (“*”) card.

| | | | | | | | |

VARIABLE**DESCRIPTION**

OPTION

Option for GENERAL. See [table](#) below.

E1, ..., E7

Specified entity. Each card must have the option specified. See [table](#) below.**The General Option:**

The “OPTION” column in the table below enumerates the allowed values for the “OPTION” variable in Card 2d for the GENERAL option. Likewise, the variables E1, ..., E7 refer to the GENERAL option of Card 2d.

Each of the following operations accept up to 7 arguments, but they may take fewer. Values of “En” left unspecified are ignored.

OPTION**DESCRIPTION**

ALL

All solid elements will be included in the set.

ELEM

Elements E1, E2, E3, ... will be included.

DELEM

Elements E1, E2, E3, ... previously added will be excluded.

PART

Elements of parts E1, E2, E3, ... will be included.

DPART

Elements of parts E1, E2, E3, ... previously added will be excluded.

BOX

Elements inside boxes E1, E2, E3, ... will be included. See *DEFINE_BOX.

DBOX

Elements inside boxes E1, E2, E3, ... previously added will be excluded.

| OPTION | DESCRIPTION |
|---------|--|
| SALECPT | <p>Elements inside a box in Structured ALE mesh. E1 here is the S-ALE mesh ID (MSHID). E2, E3, E4, E5, E6, E7 correspond to XMIN, XMAX, YMIN, YMAX, ZMIN, ZMAX. They are the minimum and the maximum nodal indices along each direction in S-ALE mesh. This option is only to be used for Structured ALE mesh and should not be used in a mixed manner with other “_GENERAL” options.</p> <p>Please refer to *ALE_STRUCTURED_MESH_CONTROL_POINTS and *ALE_STRUCTURED_MESH_CONTROL for more details.</p> |
| SALEFAC | <p>Elements on the face of Structured ALE mesh. E1 here is the S-ALE mesh ID (MSHID). E2, E3, E4, E5, E6, E7 correspond to -X, +X, -Y, +Y, -Z, +Z faces. Assigning 1 to these 6 values would include all the boundary elements at these faces in the segment set. This option is only to be used for Structured ALE mesh and should not be used in a mixed manner with other “_GENERAL” options.</p> <p>Please refer to *ALE_STRUCTURED_MESH_CONTROL_POINTS and *ALE_STRUCTURED_MESH_CONTROL for more details.</p> |

Remarks:

1. **Solvers and Mesh.** This field is used by a non-mechanics solver to create a set defined on that solver’s mesh. By default, the set refers to the mechanics mesh.

*SET_SOLID_ADD

Purpose: Define a solid set by combining solid sets.

| | | | | | | | | |
|----------|------|--------|---|---|---|---|---|---|

VARIABLE

DESCRIPTION

SID Set ID of new solid set. All solid sets should have a unique set ID.

SOLVER Name of solver using this set (MECH, CESE, etc.)

SSID[N] The Nth solid set ID.

Remarks:

1. **Solver.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

***SET_SOLID_INTERSECT**

Purpose: Define a solid set as the intersection, \cap , of a series of solid sets. The new solid set, SID, contains all common elements of all solid sets SSID_n.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|---|---|---|---|---|---|
| Variable | SID | SOLVER | | | | | | |
| Type | I | A | | | | | | |
| Default | none | MECH | | | | | | |
| Remarks | | 1 | | | | | | |

Solid Element Set Cards. For each solid element SID in the intersection input one field. Include as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|-------|-------|-------|-------|-------|-------|-------|
| Variable | SSID1 | SSID2 | SSID3 | SSID4 | SSID5 | SSID6 | SSID7 | SSID8 |
| Type | I | I | I | I | I | I | I | I |

VARIABLE**DESCRIPTION**

| | |
|---------|--|
| SID | Set ID of new solid set. All solid sets should have a unique set ID. |
| SOLVER | Name of solver using this set (MECH, CESE, etc.) |
| SSID[N] | The N th solid set ID |

Remarks:

1. **Solver.** This field is used by a non-mechanics solver to create a set defined on that solver's mesh. By default, the set refers to the mechanics mesh.

*SET_TSHELL_{OPTION1}_{OPTION2}

For OPTION1 the available options are:

- <BLANK>
- GENERATE
- GENERAL

For OPTION2 the available option is:

COLLECT

The option GENERATE will generate a block of thick shell element IDs between a starting ID and an ending ID. An arbitrary number of blocks can be specified to define the set.

Purpose: Define a set of thick shell elements.

Card Summary:

Card 1. This card is required.

| | | | | | | | |
|-----|--|--|--|--|--|--|--|
| SID | | | | | | | |
|-----|--|--|--|--|--|--|--|

Card 2a. This card is included if and only if the keyword option is unset (<BLANK>). Include as many cards as needed. This input ends at the next keyword ("*") card.

| Card 2c | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|----|----|----|----|----|----|----|
| Variable | OPTION | E1 | E2 | E3 | E4 | E5 | E6 | E7 |
| Type | A | I | I | I | I | I | I | I |

| VARIABLE | DESCRIPTION |
|-------------|--|
| OPTION | Option for GENERAL. See table below. |
| E1, ..., E7 | Specified entity. Each card must have the option specified. See table below. |

The General Option:

The “OPTION” column in the table below enumerates the allowed values for the “OPTION” variable in Card 2 for the GENERAL option. Likewise, the variables E1, ..., E7 refer to the GENERAL option Card 2.

Each of the following operations accept up to 7 arguments, but they may take fewer. Values of “En” left unspecified are ignored.

| OPTION | DESCRIPTION |
|--------|---|
| ALL | All thick shell elements will be included in the set. |
| ELEM | Elements E1, E2, E3, ... will be included. |
| DELEM | Elements E1, E2, E3, ... previously added will be excluded. |
| PART | Elements of parts E1, E2, E3, ... will be included. |

| OPTION | DESCRIPTION |
|---------------|---|
| DPART | Elements of parts E1, E2, E3, ... previously added will be excluded. |
| BOX | Elements inside boxes E1, E2, E3, ... will be included. (see *DEFINE_BOX) |
| DBOX | Elements inside boxes E1, E2, E3, ... previously added will be excluded. |

***TERMINATION**

The keyword ***TERMINATION** provides an alternative way of stopping the calculation before the termination time is reached. The termination time is specified on the ***CONTROL_TERMINATION** input and will terminate the calculation whether or not the options available in this section are active. Different types of termination may be defined:

***TERMINATION_BODY**

***TERMINATION_CONTACT**

***TERMINATION_CURVE**

***TERMINATION_DELETED_SHELLS**

***TERMINATION_DELETED_SOILDS**

***TERMINATION_NODE**

***TERMINATION_SENSOR**

*TERMINATION

*TERMINATION_BODY

*TERMINATION_BODY

Purpose: Terminate calculation based on rigid body displacements. For *TERMINATION_BODY the analysis terminates when the center of mass displacement of the rigid body specified reaches either the maximum or minimum value (stops 1, 2 or 3) or the displacement magnitude of the center of mass is exceeded (stop 4). If more than one condition is input, the analysis stops when any of the conditions is satisfied. Termination by other means than *TERMINATION input is controlled by the *CONTROL_TERMINATION control card. Note that this type of termination is not active during dynamic relaxation.

Part Cards. Add one card for each part having termination criterion. Include as many cards as necessary. This input terminates at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|---|---|---|---|
| Variable | PID | STOP | MAXC | MINC | | | | |
| Type | I | I | F | F | | | | |
| Default | none | none | - | - | | | | |

VARIABLE

DESCRIPTION

| | |
|------|---|
| PID | Part ID of rigid body, see *PART_OPTION. |
| STOP | Stop criterion: EQ.1: global x direction, EQ.2: global y direction, EQ.3: global z direction, EQ.4: stop if displacement magnitude is exceeded. |
| MAXC | Maximum (most positive) displacement, options 1, 2, 3 and 4: EQ.0.0: MAXC set to 1.0e21. |
| MINC | Minimum (most negative) displacement, options 1, 2 and 3 above only: EQ.0.0: MINC set to -1.0e21. |

***TERMINATION_CONTACT**

Purpose: The analysis terminates when the magnitude of the contact interface resultant force is zero. If more than one contact condition is input, the analysis stops when any of the conditions is satisfied. Termination by means other than *TERMINATION input is controlled by the *CONTROL_TERMINATION control card. Note that this type of termination is not active during dynamic relaxation and does not apply to 2D contact types.

Contact ID Cards. Add one card for each contact ID having a termination criterion. Include as many cards as necessary. This input terminates at the next keyword (“*”) card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|-----|-------|-----|---|---|---|
| Variable | CID | ACTIM | DUR | THRES | DOF | | | |
| Type | I | F | F | F | I | | | |
| Default | none | none | ↓ | 0.0 | 0 | | | |

| <u>VARIABLE</u> | <u>DESCRIPTION</u> |
|-----------------|--|
| CID | Contact ID. The contact ID is defined by the ordering of the contact input unless the TITLE option which allows the CID to be defined is used in the *CONTACT section. |
| ACTIM | Activation time. |
| DUR | Time duration of null resultant force prior to termination. This time is tracked only after the activation time is reached and the contact resultant forces are zero. EQ.0.0: Immediate termination after null force is detected. |
| THRES | Any measured force magnitude below or equal to this specified threshold is taken as a null force. |
| DOF | Option to consider only the force magnitude in the <i>x</i> , <i>y</i> , or <i>z</i> global directions corresponding to DOF = 1, 2, and 3, respectively. |

*TERMINATION

*TERMINATION_CURVE

*TERMINATION_CURVE

Purpose: Terminate the calculation when the load curve value returns to zero. This termination can be used with the contact option *CONTACT_AUTO_MOVE. With this option, the load curve is modified to account for the movement of the master surface.

Load Curve Card. For each load curve used as a termination criterion add a card. Include as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|---|---|---|---|---|---|
| Variable | LCID | ATIME | | | | | | |
| Type | I | F | | | | | | |
| Default | none | ↓ | | | | | | |

VARIABLE

DESCRIPTION

LCID

Load curve ID governing termination.

ATIME

Activation time. After this time the load curve is checked.

EQ.0.0: termination will occur after the load curve value becomes nonzero and then returns to zero

***TERMINATION_DELETED_SHELLS_{OPTION}**

Available options include:

<BLANK>

SET

Purpose: Terminate the calculation when the number of deleted shells for a specified part ID exceeds the value defined here. This input has no effect for a part ID that is left undefined. Generally, this option should be used with the NFAIL1 and NFAIL4 parameters that are defined in the *CONTROL_SHELL control information.

When using the SET option, termination will occur when NDS elements are deleted in any one of the parts in the part set PSID.

Part (set) Cards. Include one card for each part having a termination criterion based on shell deletion. Include as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|------|---|---|---|---|---|---|
| Variable | PID/PSID | NDS | | | | | | |
| Type | I | I | | | | | | |
| Default | none | none | | | | | | |

VARIABLE

DESCRIPTION

PID / PSID

Part ID or if option SET is active, part set ID.

NDS

Number of elements that must be deleted for the specified part ID's, before an error termination occurs.

*TERMINATION

*TERMINATION_DELETED_SOLIDS

*TERMINATION_DELETED_SOLIDS_{OPTION}

Available options include:

<BLANK>

SET

Purpose: Terminate the calculation when the number of deleted solids for a specified part ID exceeds the value defined here. This input has no effect for a part ID that is left undefined.

When using the SET option, termination will occur when NDS elements are deleted in any one of the parts in the part set PSID.

Part (set) Cards. Include one card for each part having a termination criterion based on solid element deletion. Include as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|-----|---|---|---|---|---|---|
| Variable | PID/PSID | NDS | | | | | | |
| Type | I | I | | | | | | |
| Default | none | 1 | | | | | | |

VARIABLE

DESCRIPTION

PID/PSID

Part ID or if option SET is active, part set ID.

NDS

Number of elements that must be deleted for the specified part ID's, before an error termination occurs.

***TERMINATION_NODE**

Purpose: Terminate calculation based on nodal point *coordinates*. The analysis terminates for *TERMINATION_NODE when the current position of the node specified reaches either the maximum or minimum value (stops 1, 2 or 3), or picks up force from any contact surface (stops 4). Termination by other means than *TERMINATION is controlled by the *CONTROL_TERMINATION control card. Note that this type of termination is not active during dynamic relaxation.

Node Cards. Include one card for each node having a termination criterion. Include as many cards as desired. This input terminates at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|---|---|---|---|
| Variable | NID | STOP | MAXC | MINC | | | | |
| Type | I | I | F | F | | | | |
| Default | none | none | ↓ | ↓ | | | | |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| NID | Node ID, see *NODE_OPTION. |
| STOP | Stop criterion: EQ.1: global <i>x</i> -direction, EQ.2: global <i>y</i> -direction, EQ.3: global <i>z</i> -direction, EQ.4: stop if node touches contact surface. |
| MAXC | Maximum (most positive) coordinate (options 1, 2 and 3) above only. |
| MINC | Minimum (most negative) coordinate (options 1, 2 and 3) above only. |

*TERMINATION

*TERMINATION_SENSOR

*TERMINATION_SENSOR

Purpose: Terminates the calculation when the switch condition defined in *SENSOR_-SWITCH is met.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | SWID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

VARIABLE

DESCRIPTION

SWID

ID of *SENSOR_SWITCH which will terminate the calculation when its condition is met. Only one *TERMINATION_SENSOR is allowed. If more than one *TERMINATION_SENSOR is defined; only the last one is effective.

Remarks:

An example allowing more than one sensor_switch to terminate calculation:

```
*SENSOR_DEFINE_ELEMENT
$ Axial force of beam element 1
44,BEAM,1,AXIAL,FORCE
*SENSOR_DEFINE_ELEMENT
$ Axial force of beam element 2
55,BEAM,21,AXIAL,FORCE
*SENSOR_SWITCH
$a switch condition is met when the axial force of beam-1 >5.0
11,SENSOR,44,GT,5.
*SENSOR_SWITCH
$a switch condition is met when the axial force of beam-2 >10.0
22,SENSOR,55,GT,10.
*SENSOR_SWITCH
$ a switch condition is met when time >50.
33,TIME, , 50
*SENSOR_SWITCH_CALC-LOGIC
$ a switch condition is met if both conditions
$ of switch-11 and switch-33 are met, I.e.,
$ axial force of beam-1>5.0 and time>50
44,11,33
*SENSOR_SWITCH_CALC-LOGIC
$ a switch condition is met if both conditions
$ of switch-22 and switch-33 are met, I.e.,
$ axial force of beam-2>10.0 and time>50
55,33,22
*SENSOR_SWITCH_CALC-LOGIC
$ a switch condition is met if the conditions
```

*TERMINATION_SENSOR

*TERMINATION

\$ of switch-44 **or** switch-55 is met, I.e.,
\$ axial force of beam-1>5.0 and time>50 **or**
\$ axial force of beam-2>10.0 and time>50
66,44,-55

*TERMINATION_SENSOR

\$ job will be terminated when the switch condition of switch-66 is met, I.e.,
\$ axial force of beam-1>5.0 and time>50 **or**
\$ axial force of beam-2>10.0 and time>50
66

***TITLE**

***TITLE**

Purpose: Define job title.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------------------|---|---|---|---|---|---|---|
| Variable | TITLE | | | | | | | |
| Type | C | | | | | | | |
| Default | LS-DYNA USER INPUT | | | | | | | |

VARIABLE

DESCRIPTION

TITLE

Heading to appear on output and in output files.

*USER

***USER_INTERFACE_OPTION**

Available options include:

CONTROL

FRICTION

FORCES

CONDUCTIVITY

Purpose: Define user defined input and allocate storage for user defined subroutines for the contact algorithms. See also *CONTROL_CONTACT.

The CONTROL option above allows the user to take information from the contact interface for further action; for example, stopping the analysis. A sample user subroutine is provided in Appendix F.

The FRICTION option may be used to modify the Coulomb friction coefficients in contact types 3, 5, or 10 (*CONTACT_SURFACE_TO_SURFACE, *CONTACT_NODES_TO_SURFACE, or *CONTACT_ONE_WAY_SURFACE_TO_SURFACE) according to contact information or a friction coefficient database. A sample user-defined friction subroutine is provided in Appendix G. For the subroutine to be called, the static friction coefficient FS on Card 2 of *CONTACT must be any nonzero value, and shell thickness offsets must be invoked in the contact by setting SHLTHK to 1 or 2 using *CONTROL_CONTACT or Opt. Card B in *CONTACT. The array length USR-FRC in *CONTROL_CONTACT should be set to a value no less than the sum of the number of history variables NOC and the number of user-defined input parameters in *USER_INTERFACE_FRICTION.

The CONDUCTIVITY option is used to define heat transfer contact conductance properties for thermal contacts.

The FORCES option is used to collect contact nodal forces from specified contact ID list for user subroutines.

Card Summary:

Card 1a. Include this card if and only if the keyword option is CONTROL, FRICTION, or CONDUCTION.

| | | | | | | | |
|------|-----|------|------|-------|--|--|--|
| IFID | NOC | NOCI | NHSV | NEHIS | | | |

| Type | F | F | F | F | F | F | F | F |

VARIABLE

DESCRIPTION

| | |
|------|---|
| IFID | Interface number |
| NOC | Number of history variables for interface. The number should not exceed the length of the array defined on *CONTROL_CONTACT. See Remark 1 . |
| NOCI | Initialize the first NOCI history variables in the input. NOCI must be smaller or equal to NOC. |

| VARIABLE | DESCRIPTION |
|-----------------|--|
| NHSV | Number of history variables per interface node (only for friction and conductivity interface). |
| NEHIS | Flag for element (material) history data provided as input quantities in subroutine usrfrc (see comments there). EQ.0: A special choice of element history variables is provided, namely plastic strain, yield stress, and material directions. GT.0: Plastic strain and element history variables up to NEHIS-1 are provided in original order. |
| UC1 | First user defined input parameter. |
| UC2 | Second user defined input parameter. |
| : | : |
| UC[N] | Last user defined input parameter, where N = NOCI. |

| Card 1b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---|---|---|---|---|---|---|
| Variable | NCONT | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

Contact ID Cards. Use as many cards as necessary to set NCONT contact IDs.

| Card 1b.1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-----------|------|------|------|------|------|------|------|------|
| Variable | CID1 | CID2 | CID3 | CID4 | CID5 | CID6 | CID7 | CID8 |
| Type | I | I | I | I | I | I | I | I |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| NCONT | Number of contact ID. LE.0: all contacts will be used. |

*USER

| <u>VARIABLE</u> | <u>DESCRIPTION</u> |
|-----------------|--|
| CID1 | First contact user ID. |
| CID2 | Second contact user ID. |
| ⋮ | ⋮ |
| CID[N] | Last contact user ID, where N = NCONT. |

Remarks:

1. **Interface Variables.** The (NOC) interface variables (of which NOCI are initialized) are passed as arguments to the user defined subroutine. See Appendix G for the full list of arguments passed to the subroutine.
2. **Segment Based Contact.** This keyword is not supported by segment based contact which is invoked by setting SOFT = 2 on optional card A of the *CONTACT card.

***USER_LOADING**

Purpose: Provide a means of applying pressure and force boundary conditions. The keyword ***USER_LOADING** activates this option. Input here is optional with the input being read until the next ****** keyword appears. The data read here is to be stored in a common block provided in the user subroutine, **LOADUD**. This data is stored and retrieved from the restart files.

Parameter Cards. Add one card for each input parameter. Include as many cards as needed. This input ends at the next keyword (******) card.

| Card 1... | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-----------|--------|--------|--------|--------|--------|--------|--------|--------|
| Variable | PARAM1 | PARAM2 | PARAM3 | PARAM4 | PARAM5 | PARAM6 | PARAM7 | PARAM8 |
| Type | F | F | F | F | F | F | F | F |
| Default | none |

VARIABLE**DESCRIPTION**

PARAM[N]

This is the Nth user input parameter.

***USER_LOADING_SET**

Purpose: Provides a means to apply user-defined loading to a set of nodes or segments. Loading could be nodal force, body force, temperature distribution, and pressure on segment or beam.

Set Cards. Add a card for each set to which a load is applied. Include as many cards as necessary. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-------|------|--------|------|------|------|--------|
| Variable | SID | LTYPE | LCID | CID | SF1 | SF2 | SF3 | IDULS |
| Type | I | A | I | I | F | F | F | I |
| Default | none | none | none | global | none | none | none | Seq. # |

VARIABLE**DESCRIPTION**

SID

ID of the set to which user-defined loading will be applied. Set type depends on the type of loading, see LTYPE.

LTYPE

Loading type:

EQ.“FORCEN”: Force a will be applied to node set SID. The load is to be given in units of force.

EQ.“BODYFN”: Body force density will be applied to node set SID. The load is to be given in units of force per volume.

EQ.“TEMPTN”: Temperature will be assigned to node set SID. This option cannot be coexist with *LOAD_THERMAL_VARIABLE. In other word, users can only use either this option or *LOAD_THERMAL_VARIABLE to specify temperature distribution, not both of them,

EQ.“PRESSSS”: Pressure will be applied to segment set SID. The load is to be given in units of force per ar-
ea.

EQ.“PRESSB”: Pressure in units of force per length will be applied to beam set SID.

| VARIABLE | DESCRIPTION |
|-----------------|---|
| LCID | Load curve, a function of time. Its current value, <i>crv</i> , is passed to user subroutine LOADSETUD. |
| CID | Optional coordinate system along which scale factors SF_i is defined. Global system is the default system. |
| SF[i] | Scale factor of loading magnitude, when LTYPE LTYPE.EQ."FORCEN": SF_i is the factor along i^{th} direction of CID. For example, set $SF_1 = 1$. and the others to zero if the load is to be applied in the positive x -direction. This applies whether the global or a local coordinate system is used. LTYPE.EQ."BODYFN": See "EQ.FORCEN" LTYPE.EQ."PRESSSS": SF_1 is used as the scale factor, SF_2 and SF_3 are ignored, LTYPE.EQ."PRESSB": Scale factor along r, s, t axis of beam. |
| IDULS | Each USER_LOADING_SET can be assigned a unique ID, which is passed to user subroutine LOADSETUD and allows multiple loading definitions by using a single user subroutine, LOADSETUD. If no value is input, LS-DYNA will assign a sequence number to each USER_LOADING_SET based on its definition sequence. |

Remarks:

*USER_LOADING_SET activates the loading defined in user subroutine LOADSETUD, part of dyn21.F. When both *USER_LOADING_SET and *USER_LOADING are defined, *USER_LOADING is only used to define user-defined parameters, PARM*n*; not to activate user subroutine LOADUD. Therefore only loading defined in LOADSETUD will be applied.

More than one loading definitions can be defined and assigned a unique ID, that enables multiple loading to be taken care of by a single subroutine, LOADSETUD, as shown below:

```
subroutine loadsetud(time,lft,llt,crv,iduls,parm)
c
c   Input (not modifiable)
c   x   : coordinate of node or element center
c   d   : displacement of node or element center
c   v   : velocity of node or element center
```

```
c      temp: temperature of node or element center
c      crv : value of LCID at current time
c      isuls : id of user_loading_set
c      parm: parameters defined in *USER_LOADING
c      Output (defined by user)
c      udl : user-defined load value
c      include 'nlqparm'
C_TASKCOMMON (aux8loc)
c      common/aux8loc/
c      & x1(nlq),x2(nlq),x3(nlq),v1(nlq),v2(nlq),v3(nlq),
c      & d1(nlq),d2(nlq),d3(nlq),temp(nlq),udl(nlq),tmp(nlq,12)
c
c      sample code
c      if (iduls.eq.100) then
c        do i=lft,llt
c          your code here
c          udl(i)=.....
c        enddo
c      elseif (iduls.eq.200) then
c        do i=lft,llt
c          udl(i)=.....
c        enddo
c      endif
c      return
c      end
```

***USER_NONLOCAL_SEARCH**

Purpose: Provides an interface for code to gather surrounding element history data by user defined strategy for each master elements. Currently this option only supports solids.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-------|-------|------|------|------|------|
| Variable | SSID | MSID | STYPE | MTYPE | R | SF1 | SF2 | SF3 |
| Type | I | I | I | I | F | F | F | F |
| Default | none | none | None | none | none | none | none | none |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|---------|-------|---------|---|---|---|---|
| Variable | NFREQ | VOLTYPE | UTYPE | NUCONST | | | | |
| Type | I | I | I | I | | | | |
| Default | 1 | none | None | none | | | | |

If **NUCONST** > 0, number of user defined parameters (48 maximum)

| Optional | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | P1 | P2 | P3 | P4 | P5 | P6 | P7 | P8 |
| Type | F | F | F | F | F | F | F | F |
| Default | none |

Location of the history variables to be gathered 8 fields per card until to the next keyword.

| History | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|------|------|------|------|------|------|
| Variable | H1 | H2 | H3 | H4 | H5 | H6 | H7 | H8 |
| Type | I | I | I | I | I | I | I | I |
| Default | none |

VARIABLE**DESCRIPTION**

| | |
|---------|--|
| SSID | Slave set ID |
| MSID | Master set ID |
| STYPE | ID type of SSID: EQ.0: part set ID, EQ.1: part ID. |
| MTYPE | ID type of MSID: EQ.0: part set ID, EQ.1: part ID, EQ.2: solid set ID, EQ.3: solid ID. |
| R | Searching distance from the center of master solid |
| SF[i] | Scale factor for each searching (a,b,c) direction. (Default = 1.0) |
| NFREQ | Number of cycle for collecting the history data (Default = 1) |
| VOLTYPE | Search geometry EQ.1: Global axes (Default), EQ.2: Material axes(*ELEMENT_SOLID_ORTHO only) |
| UTYPE | User specified function type |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| NUCONST | Number of user defined parameters |
| P[i] | User defined parameters (48 maximum) |
| H[i] | Location of the history variable to be gathered for this function |

Remarks:

*USER_NONLOCAL_SEARCH activates the user subroutines USER_NUNONL and USER_NUNONL_SMOOTH, part of dyn21.F. More than one definitions can be defined and assigned a unique ID, that enables multiple none local data to be taken care of by a single interface, as shown below: This provide an open interface for user applying the special function using the neighboring elements history data.

```

subroutine user_nunonl(nnon,ictl,rctl,auxvec,lochvh)
  dimension ictl(40,*),rctl(40,*),auxvec(*),lochvh(*)
  MINDEX peid,ped1,plst,pelst,peslt,phst,ptmp,pcnst

Restart Input Data

In general three categories of restart actions are possible with LS-DYNA and are outlined in the following discussion:

1. A simple restart occurs when LS-DYNA was interactively stopped before reaching the termination time. Then, by specifying the **R=rtf** command line option on the execution line, LS-DYNA restarts the calculation from the termination point. The calculation will pick up at the specified termination time. see INTRODUCTION, Execution Syntax. No additional input deck is required.
2. For small modifications of the restart run LS-DYNA offer a “small restart” capability which can
 - a) reset termination time,
 - b) reset output printing interval,
 - c) reset output plotting interval,
 - d) delete contact surfaces,
 - e) delete elements and parts,
 - f) switch deformable bodies to rigid,
 - g) switch rigid bodies to deformable,
 - h) change damping options.

All modifications to the problem made with the restart input deck will be reflected in subsequent restart dumps. All the members of the file families are consecutively numbered beginning from the last member prior to termination.

For a small restart run a *small input deck* replaces the standard input deck on the execution line which must have at least the following command line arguments:

LS-DYNA I=**restartinput** R=**D3DUMPnn**

where **D3DUMPnn** (or whatever name is chosen for the family member) is the *n*th restart file from the last run where the data is taken. LS-DYNA automatically detects that a small input deck is used since the I=**restartinput** file may contain *only* the *restart* keywords (excluding *STRESS_INITIALIZATION):

*CHANGE_OPTION

Restart Input Data

*CONTROL_DYNAMIC_RELAXATION
*CONTROL_SHELL
*CONTROL_TERMINATION
*CONTROL_TIMESTEP
*DAMPING_GLOBAL
*DATABASE_OPTION
*DATABASE_BINARY_OPTION
*DELETE_OPTION
*INTERFACE_SPRINGBACK_LSDYNA
*RIGID_DEFORMABLE_OPTION
*STRESS_INITIALIZATION_{OPTION}
*TERMINATION_OPTION
*TITLE
*KEYWORD
*CONTROL_CPU
*DEFINE_OPTION
*SET_OPTION

The user has to take care that nonphysical modifications to the input deck are avoided; otherwise, complete nonsense may be the result.

3. If many modifications are desired a *full restart* may be the appropriate choice. A full restart is selected by including a full model along with a *STRESS_INITIALIZATION keyword card and possibly other restart cards. As mentioned in the *Restart Analysis* subsection of the *Introduction* portion of the manual, either all parts or some subset of parts can be made for the stress initialization.

Remarks:

- a) In a full restart, only those nodes and elements defined in the full restart deck will be present in the analysis after the full restart is initiated. But as a convenience, any of those nodes or elements can be deleted using the *DELETE command.

Restart Input Data

- b) In a small restart, velocities of nodes come from the dump file by default but those velocities can be changed using *CHANGE_VELOCITY_....
- c) In a full restart, velocities of pre-existing nodes come from the dump file by default but those velocities can be changed using *CHANGE_VELOCITY_.... To set the starting velocities for new nodes in a full restart, use *INITIAL_VELOCITY_....
- d) Pre-existing contacts, in general, carry forward seamlessly using data from the d3dump (or d3full if MPP) database. It is important that the contact ID(s) in the full restart input deck match the contact ID(s) in the original input deck if the intent is for the contacts to be initialized using data from the d3dump/d3full database. EXCEPTION: In the special case of MPP, a *CONTACT_AUTOMATIC_GENERAL contact in the full restart input deck is treated as a brand new contact and is not initialized using data from d3full.
- e) Parameters used in a restart input deck must be defined in that same restart input deck using *PARAMETER.
- f) Only sets utilizing element IDs and node IDs are permitted in a small restart deck; part IDs are not recognized. Sets referenced by other commands in a small restart deck must be defined in the small restart deck.

*CHANGE_OPTION

Purpose: Change solution options.

Available options include:

BOUNDARY_CONDITION
CONTACT_SMALL_PENETRATION
CURVE_DEFINITION
OUTPUT
RIGIDWALL_GEOMETRIC
RIGIDWALL_PLANAR
RIGID_BODY_CONSTRAINT
RIGID_BODY_INERTIA
RIGID_BODY_STOPPER
STATUS_REPORT_FREQUENCY
THERMAL_PARAMETERS
VELOCITY
VELOCITY_GENERATION
VELOCITY_NODE
VELOCITY_RIGID_BODY
VELOCITY_ZERO

Boundary Condition Cards. This card 1 format is for the **BOUNDARY_CONDITION** keyword option. Add one card for each boundary condition. This card imposes *additional* boundary conditions. It does not remove previously imposed conditions (for example, this option will not free a fixed node). This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|---|---|---|---|---|---|
| Variable | NID | BCC | | | | | | |
| Type | I | I | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|-----|---|
| NID | Nodal point ID, see also *NODE. |
| BCC | New translational boundary condition code: EQ.1: constrained x displacement, EQ.2: constrained y displacement, EQ.3: constrained z displacement, EQ.4: constrained x and y displacements, EQ.5: constrained y and z displacements, EQ.6: constrained z and x displacements, EQ.7: constrained x , y , and z displacements. |

Small Penetration Check Cards. This Card 1 format is for the **CONTACT_SMALL_PENETRATION** keyword option. Set one value for each contact surface ID where the small penetration check is to be turned on. The input terminates at the next keyword (“*”) card. See the PENCHK variable in *CONTACT.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-----|-----|-----|-----|
| Variable | ID1 | ID2 | ID3 | ID4 | ID5 | ID6 | ID7 | ID8 |
| Type | I | I | I | I | I | I | I | I |

VARIABLE**DESCRIPTION**

| | |
|--------|-------------------------------------|
| ID n | Contact ID for surface number n . |
|--------|-------------------------------------|

Load Curve Redefinition Cards. This Card 1 format is for the **CURVE_DEFINITION** keyword option. *The new load curve must contain the same number of points as the curve it replaces.* The curve should be defined according to the DEFINE_CURVE section of the manual. This input terminates when the next “*” card is encountered. Offsets and scale factors are ignored.

LCID Load curve ID

ASCII Output Overwrite Card. This format applies to the **OUTPUT** keyword option.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|---|---|---|---|---|---|---|
| Variable | IASCII | | | | | | | |
| Type | I | | | | | | | |

VARIABLE

DESCRIPTION

IASCII Flag to control manner of outputting ASCII data requested by *DATABASE_OPTION commands in a full restart deck:
EQ.0: Full restart overwrites existing ASCII output (default),
EQ.1: Full restart appends to existing ASCII output.

Rigidwall modification. The format for the **RIGIDWALL_GEOMETRIC** and **RIGIDWALL_PLANAR** cards is identical to the original cards (see [*RIGIDWALL_GEOMETRIC](#) and [*RIGIDWALL_PLANAR](#)), however there are restrictions on the entries that may be changed: only those entries that define the size and orientation of the rigid walls may be changed, but not any of the others (e.g., the type). A rigidwall may only be modified when doing a full restart.

Rigid Body Constraint Modification Cards. This format for Card 1 applies to the **RIGID_BODY_CONSTRAINT** keyword option. This option can change translation and rotational boundary condition on a rigid body. This input ends at the next keyword ("*") card. See CONSTRAINED_RIGID_BODIES.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|----|----|---|---|---|---|---|
| Variable | PID | TC | RC | | | | | |

VARIABLE**DESCRIPTION**

| | |
|-----|---|
| PID | Part ID, see *PART. |
| TC | Translational constraint: EQ.0: no constraints, EQ.1: constrained x displacement, EQ.2: constrained y displacement, EQ.3: constrained z displacement, EQ.4: constrained x and y displacements, EQ.5: constrained y and z displacements, EQ.6: constrained z and x displacements, EQ.7: constrained x , y , and z displacements. |
| RC | Rotational constraint: EQ.0: no constraints, EQ.1: constrained x rotation, EQ.2: constrained y rotation, EQ.3: constrained z rotation, EQ.4: constrained x and y rotations, EQ.5: constrained y and z rotations, EQ.6: constrained z and x rotations, EQ.7: constrained x , y , and z rotations. |

Card sets for *RIGID_BODY_INERTIA* keyword option. This option supports changing the mass and inertia properties of a rigid body. Include as many pairs of the following two cards as necessary. This input ends at the next keyword ("*") card. The inertia tensor is specified relative to the coordinate system set in *MAT_RIGID at the start of the calculation, which is fixed in the rigid body and tracks the rigid body rotation.

*RESTART INPUT DATA

*CHANGE

| PID | Part ID, see *PART. |
| TM | Translational mass. |
| IXX | I_{xx} , xx component of inertia tensor. |
| IXY | I_{xy} |
| IXZ | I_{xz} |
| IYY | I_{yy} |
| IYZ | I_{yz} |
| IZZ | I_{zz} |

Card sets for the *RIGID_BODY_STOPPERS* keyword option. This option is for redefining existing stoppers. Include as many pairs of cards as necessary. This input terminates when the next "*" card is encountered. See *CONSTRAINED_RIGID_BODY_STOPPERS. Note that new stopper definitions cannot be introduced in this section. Existing stoppers can be modified.

CHANGE**RESTART INPUT DATA**

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----------|-------|-------|--------|--------|--------|----------|-----|
| Variable | PID | LCMAX | LCMIN | PSIDMX | PSIDMN | LCVMNX | DIR | VID |
| Type | I | I | I | I | I | I | I | I |

|----------|-------|------------------|---|---|---|---|---|---|
| Variable | BIRTH | DEATH | | | | | | |
| Type | F | F | | | | | | |
| Default | 0 | 10 ²⁸ | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|--------|---|
| PID | Part ID of master rigid body, see *PART. |
| LCMAX | Load curve ID defining the maximum coordinate as a function of time: EQ.0: no limitation of the maximum displacement. New curves can be defined by the *DEFINE_CURVE within the present restart deck. (Not applicable for small deck restart). |
| LCMIN | Load curve ID defining the minimum coordinate as a function of time: EQ.0: no limitation of the minimum displacement. New curves can be defined by the *DEFINE_CURVE within the present restart deck. (Not applicable for small deck restart). |
| PSIDMX | Optional part set ID of rigid bodies that are slaved in the maximum coordinate direction to the master rigid body. This option requires additional input by the *SET_PART definition. |

| VARIABLE | DESCRIPTION |
|----------|--|
| PSIDMN | Optional part set ID of rigid bodies that are slaved in the minimum coordinate direction to the master rigid body. This option requires additional input by the *SET_PART definition. |
| LCVMNX | Load curve ID which defines the maximum absolute value of the velocity that is allowed within the stopper: EQ.0: no limitation of the minimum displacement. |
| DIR | Direction stopper acts in: EQ.1: x -translation, EQ.2: y -translation, EQ.3: z -translation, EQ.4: arbitrary, defined by vector VID, EQ.5: x -axis rotation, EQ.6: y -axis rotation, EQ.7: z -axis rotation, EQ.8: arbitrary, defined by vector VID. |
| VID | Vector for arbitrary orientation of stopper. The vector must be defined by a *DEFINE_VECTOR within the present restart deck. |
| BIRTH | Time at which stopper is activated. |
| DEATH | Time at which stopper is deactivated. |

Remarks:

The optional definition of part sets in minimum or maximum coordinate directions allows the motion to be controlled in an arbitrary direction.

D3HSP Interval Change Card. This card format applies to the **STATUS_REPORT_FREQUENCY** keyword option.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|---|---|---|---|---|---|---|
| Variable | IKEDIT | | | | | | | |
| Type | I | | | | | | | |

| VARIABLE | DESCRIPTION |
|----------|---|
| IKEDIT | Problem status report interval steps in the D3HSP output file: EQ.0: interval remains unchanged. |

Card set for the *THERMAL_PARAMETERS* keyword option. This option is for changing the parameters used by a thermal or coupled structural/thermal analysis. See *CONTROL_THERMAL. Add the two following cards to the deck (they do not repeat).

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|------|------|-------|------|---|---|
| Variable | TS | DT | TMIN | TMAX | DTEMP | TSCP | | |
| Type | I | F | F | F | F | F | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|-----|---|---|---|---|---|---|
| Variable | REFMAX | TOL | | | | | | |
| Type | I | F | | | | | | |

| VARIABLE | DESCRIPTION |
|----------|--|
| TS | Thermal time step code: EQ.0: No change, EQ.1: Fixed time step, EQ.2: variable time step. |
| DT | Thermal time step on restart: EQ.0: No change. |
| TMIN | Minimum thermal time step: EQ.0: No change. |
| TMAX | Maximum thermal time step: EQ.0: No change. |

*RESTART INPUT DATA

*CHANGE

| VARIABLE | DESCRIPTION |
|----------|---|
| DTEMP | Maximum temperature change in a thermal time step: EQ.0: No change. |
| TSCP | Time step control parameter (0.0 < TSCP < 1.0): EQ.0: No change. |
| REFMAX | Maximum number of reformations per thermal time step: EQ.0: No change. |
| TOL | Non-linear convergence tolerance: EQ.0: No change. |

Node Set Velocity Card Sets. The formats for Cards 1 and 2 apply to the **VELOCITY** and **VELOCITY_ONLY** keyword options. These options are for setting velocity fields on node sets at restart. For each node set add one pair of the following cards. This input ends at the next keyword ("*") card. Undefined nodes (not listed on a set velocity card) will have their nodal velocities reset to zero if a *CHANGE_VELOCITY definition is encountered in the restart deck. However, if any of the *CHANGE_VELOCITY definitions have ONLY appended, then only the specified nodes will have their nodal velocities modified.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | NSID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |
| Remark | 1 | | | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|----|----|-----|-----|-----|---|---|
| Variable | VX | VY | VZ | VXR | VYR | VZR | | |
| Type | F | F | F | F | F | F | | |
| Default | 0. | 0. | 0. | 0. | 0. | 0. | | |

VARIABLE**DESCRIPTION**

| | |
|------|---|
| NSID | Nodal set ID containing nodes for initial velocity. |
| VX | Velocity in x -direction. |
| VY | Velocity in y -direction. |
| VZ | Velocity in z -direction. |
| VXR | Rotational velocity about the x -axis. |
| VYR | Rotational velocity about the y -axis. |
| VZR | Rotational velocity about the z -axis. |

Remarks:

1. If a node is initialized on more than one input card set, then the last set input will determine its velocity, unless it is specified on a `*CHANGE_VELOCITY_-NODE` card.
2. Undefined nodes will have their nodal velocities set to zero if a `*CHANGE_-VELOCITY` definition is encountered in the restart deck.
3. If both `*CHANGE_VELOCITY` and `*CHANGE_VELOCITY_ZERO` cards are defined then all velocities will be reset to zero.

Velocity generation cards. The velocity generation cards for the **VELOCITY_GENERATION** option are identical to the standard velocity generation cards (see [*INITIAL_VELOCITY_GENERATION](#)), and all parameters may be changed.

*RESTART INPUT DATA

*CHANGE

Nodal Point Velocity Cards. This format applies to the **VELOCITY_NODE** and **VELOCITY_NODE_ONLY** keyword options. These option support changing nodal velocities. This input ends at the next keyword ("**") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|----|----|----|-----|-----|-----|---|
| Variable | NID | VX | VY | VZ | VXR | VYR | VZR | |
| Type | I | F | F | F | F | F | F | |
| Default | none | 0. | 0. | 0. | 0. | 0. | 0. | |

VARIABLE

DESCRIPTION

| | |
|-----|---|
| NID | Node ID |
| VX | Translational velocity in x -direction. |
| VY | Translational velocity in y -direction. |
| VZ | Translational velocity in z -direction. |
| VXR | Rotational velocity about the x -axis. |
| VYR | Rotational velocity about the y -axis. |
| VZR | Rotational velocity about the z -axis. |

Remarks:

1. Undefined nodes (not listed on a point velocity card) will have their nodal velocities reset to zero if a *CHANGE_VELOCITY_NODE definition is encountered in the restart deck. However, if any of the *CHANGE_VELOCITY or CHANGE_VELOCITY_NODE definitions have ONLY appended, then only the specified nodes will have their nodal velocities modified.
2. If a node is initialized on more than one input card set, then the last set input will determine its velocity, unless it is specified on a *CHANGE_VELOCITY_NODE card.
3. If both *CHANGE_VELOCITY and *CHANGE_VELOCITY_ZERO cards are defined then all velocities will be reset to zero.

Rigid Body Velocity Cards. This Card 1 format applies to the **VELOCITY_RIGID_BODY** keyword option. This option allows for setting the velocity components of a rigid body at restart. Include as many of these cards as desired. This input ends at the next keyword ("*****") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|----|----|----|-----|-----|-----|---|
| Variable | PID | VX | VY | VZ | VXR | VYR | VZR | |
| Type | I | F | F | F | F | F | F | |
| Default | none | 0. | 0. | 0. | 0. | 0. | 0. | |

VARIABLE**DESCRIPTION**

| | |
|-----|---|
| PID | Part ID of rigid body. |
| VX | Translational velocity in x -direction. |
| VY | Translational velocity in y -direction. |
| VZ | Translational velocity in z -direction. |
| VXR | Rotational velocity about the x -axis. |
| VYR | Rotational velocity about the y -axis. |
| VZR | Rotational velocity about the z -axis. |

Remarks:

1. Rotational velocities are defined about the center of mass of the rigid body.
2. Rigid bodies not defined in this section will not have their velocities modified.

Restarting the Model at Rest. The **VELOCITY_ZERO** option resets the velocities to zero at the start of the restart. There are no data cards associated with ***CHANGE_VELOCITY_ZERO**.

RESTART INPUT DATA

*CONTROL_DYNAMIC_RELAXATION

*CONTROL_DYNAMIC_RELAXATION

Purpose: Define controls for dynamic relaxation.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|-------|--------|----------|--------|--------|-------|--------|
| Variable | NRCYCK | DRTOL | DRFCTR | DRTERM | TSSFDR | IRELAL | EDTTL | IDRFLG |
| Type | I | F | F | F | F | I | F | I |
| Default | 250 | 0.001 | 0.995 | ∞ | TSSFAC | 0 | 0.0 | 0 |
| Remarks | 1 | 1 | 1 | 1 | 1 | | | 1 |

VARIABLE

DESCRIPTION

| | |
|--------|--|
| NRCYCK | Number of iterations between convergence checks, for dynamic relaxation option |
| DRTOL | Convergence tolerance for dynamic relaxation option |
| DRFCTR | Dynamic relaxation factor |
| DRTERM | Optional termination time for dynamic relaxation. Termination occurs at this time or when convergence is attained. |
| TSSFDR | Scale factor for computed time step during dynamic relaxation. If zero, the value is set to TSSFAC defined on *CONTROL_TERMINATION. After converging, the scale factor is reset to TSSFAC. |
| IRELAL | Automatic control for dynamic relaxation option based on algorithm of Papadrakakis [1981]: EQ.0: not active, EQ.1: active. |
| EDTTL | Convergence tolerance on automatic control of dynamic relaxation. |
| IDRFLG | Dynamic relaxation flag for stress initialization: EQ.0: not active, EQ.1: dynamic relaxation is activated. |

Remarks:

1. **Restart before Dynamic Relaxation Convergence.** If a dynamic relaxation relaxation analysis is being restarted at a point before convergence was obtained, then NRCYCK, DRTOL, DRFCTR, DRTERM and TSSFDR will default to their previous values, and IDRFLG will be set to 1.
2. **Restart from Normal Transient Analysis.** If dynamic relaxation is activated after a restart from a normal transient analysis, LS-DYNA continues the output of data as it would without the dynamic relaxation being active. This is unlike the dynamic relaxation phase at the beginning of the calculation when a separate database is not used. Only load curves that are flagged for dynamic relaxation are applied after restarting.

*CONTROL_SHELL

Purpose: Change failure parameters NFAIL1 and NFAIL4 if necessary. These parameters must be nonzero in the initial run.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---|---|---|---|---|---|---|---|
| Variable | | | | | | | | |
| Type | | | | | | | | |

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---|---|---|---|---|--------|--------|---------|
| Variable | | | | | | NFAIL1 | NFAIL4 | PSNFAIL |
| Type | | | | | | I | I | I |

VARIABLE

DESCRIPTION

NFAIL1

Flag to check for highly distorted under-integrated shell elements, print a message, and delete the element or terminate. Generally, this flag is not needed for one point elements that do not use the warping stiffness. A distorted element is one where a negative jacobian exists within the domain of the shell, not just at integration points. The checks are made away from the integration points to enable the bad elements to be deleted before an instability leading to an error termination occurs. This test will increase CPU requirements for one point elements.

EQ.1: print message and delete element.

EQ.2: print message, write d3dump file, and terminate

GT.2: print message and delete element. When NFAIL1 elements are deleted, LS-Dyna writes the d3dump file and terminates. These NFAIL1 failed elements also include all shell elements that failed for other reasons than distortion. Before the d3dump file is written, NFAIL1 is doubled, so the run can immediately be continued if desired.

| VARIABLE | DESCRIPTION |
|----------|---|
| NFAIL4 | <p data-bbox="474 260 1409 449">Flag to check for highly distorted fully-integrated shell elements, print a message, and delete the element or terminate. Generally, this flag is recommended. A distorted element is one where a negative jacobian exists within the domain of the shell, not just at integration points.</p> <p data-bbox="474 466 1409 571">The checks are made away from the integration points to enable the bad elements to be deleted before an instability leading to an error termination occurs.</p> <p data-bbox="506 596 1075 630">EQ.1: print message and delete element.</p> <p data-bbox="506 655 1279 688">EQ.2: print message, write d3dump file, and terminate</p> <p data-bbox="506 714 1409 974">GT.2: print message and delete element. When NFAIL4 elements are deleted, LS-Dyna writes the d3dump file and terminates. These NFAIL4 failed elements also include all shell elements that failed for other reasons than distortion. Before the d3dump file is written, NFAIL4 is doubled, so the run can immediately be continued if desired.</p> |
| PSNFAIL | <p data-bbox="474 1008 1409 1119">Optional shell part set ID specifying which part IDs are checked by the NFAIL1, NFAIL4, and W-MODE options. If zero, all shell part IDs are included.</p> |

RESTART INPUT DATA

***CONTROL_TERMINATION**

*CONTROL_TERMINATION

Purpose: Stop the job.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|--------|--------|---|---|---|---|---|---|
| Variable | ENDTIM | ENDCYC | | | | | | |
| Type | F | I | | | | | | |

VARIABLE

DESCRIPTION

ENDTIM

Termination time:

EQ.0.0: Termination time remains unchanged.

ENDCYC

Termination cycle. The termination cycle is optional and will be used if the specified cycle is reached before the termination time.

EQ.0.0: Termination cycle remains unchanged.

Remarks:

This is a reduced version of the *CONTROL_TERMINATION card used in the initial input deck.

***CONTROL_TIMESTEP**

Purpose: Set time step size control using different options.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-------|--------|------|-------|-------|------|---|---|
| Variable | DUMMY | TSSFAC | ISDO | DUMMY | DT2MS | LCTM | | |
| Type | F | F | I | F | F | I | | |

VARIABLE**DESCRIPTION**

DUMMY

Dummy field, see [Remark 1](#) below.

TSSFAC

Scale factor for computed time step.

EQ.0.0: TSSFAC remains unchanged.

ISDO

Basis of time size calculation for 4-node shell elements. 3-node shells use the shortest altitude for options 0 and 1 and the shortest side for option 2. This field has no relevance to solid elements, which use a length based on the element volume divided by the largest surface area.

EQ.0: characteristic length is given by

$$\frac{\text{area}}{\min(\text{longest side, longest diagonal})}$$

EQ.1: characteristic length is given by

$$\frac{\text{area}}{\text{longest diagonal}}$$

EQ.2: based on bar wave speed and,

$$\max \left[\text{shortest side}, \frac{\text{area}}{\min(\text{longest side, longest diagonal})} \right]$$

WARNING: Option 2 can give a much larger time step size that can lead to instabilities in some applications, especially when triangular elements are used.

DUMMY

Dummy field, see [Remark 1](#) below.

| <u>VARIABLE</u> | <u>DESCRIPTION</u> |
|-----------------|--|
| DT2MS | New time step for mass scaled calculations. Mass scaling must be active in the time zero analysis. EQ.0.0: DT2MS remains unchanged. |
| LCTM | Load curve ID that limits maximum time step size: EQ.0: LCTM remains unchanged. |

Remarks:

1. **Dummy Fields.** This a reduced version of the *CONTROL_TIMESTEP used in the initial analysis. The dummy fields are included to maintain compatibility. If using free format input then a 0.0 should be entered for the dummy values.

***DAMPING_GLOBAL**

Purpose: Define mass weighted nodal damping that applies globally to the deformable nodes.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|--------|---|---|---|---|---|---|
| Variable | LCID | VALDMP | | | | | | |
| Type | I | F | | | | | | |
| Default | 0 | 0.0 | | | | | | |

VARIABLE**DESCRIPTION**

LCID

Load curve ID which specifies node system damping:

EQ.n: system damping is given by load curve n. The damping force applied to each node is $f = -d(t) mv$, where $d(t)$ is defined by load curve n.

VALDMP

System damping constant, d (this option is bypassed if the load curve number defined above is nonzero).

*DATABASE_OPTION

Purpose: Change the output interval for ASCII files. If a file is not specified in the restart deck, then the output interval for the file will remain unchanged.

Options for ASCII files include:

| | |
|----------------|---|
| SECFORC | Cross section forces. |
| RWFORC | Wall forces. |
| NODOUT | Nodal point data. |
| ELOUT | Element data. |
| GLSTAT | Global data. |
| DEFORC | Discrete elements. |
| MATSUM | Material energies. |
| NCFORC | Nodal interface forces. |
| RCFORC | Resultant interface forces. |
| DEFGEO | Deformed geometry file |
| SPCFORC | Set dt for spc reaction forces. |
| SWFORC | Nodal constraint reaction forces (spot welds and rivets). |
| ABSTAT | Set dt for airbag statistics. |
| NODFOR | Set dt for nodal force groups. |
| BNDOUT | Boundary condition forces and energy |
| RBDOUT | Set dt for rigid body data. |
| GCEOUT | Set dt for geometric contact entities. |
| SLEOUT | Set dt for sliding interface energy. |
| JNTFORC | Set dt for joint force file. |
| SBTOUT | Set dt for seat belt output file. |
| AVSFLT | Set dt for AVS database. |
| MOVIE | Set dt for MOVIE. |
| MPGS | Set dt for MPGS. |
| TPRINT | Set dt for thermal file. |

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|----|---|---|---|---|---|---|---|
| Variable | DT | | | | | | | |
| Type | F | | | | | | | |

VARIABLE**DESCRIPTION**

DT Time interval between outputs:
 EQ.0.0: output interval is unchanged.

Remarks:

1. **File Output Termination.** To terminate output to a particular file set DT to a high value.
2. **NODOUT Results.** If IACCOP = 2 was specified in *CONTROL_OUTPUT, the best results are obtained in the NODOUT file by keeping the same DT on restart. When DT is changed for NODOUT, oscillations may occur around the restart time. If DT is larger than initially specified in the original input file, more memory is required to store the time states for the averaging than was originally allocated. A warning message is printed, and the filtering is applied using the available memory. When DT is smaller than initially specified, more oscillations may appear in the output than earlier in the calculation because the frequency content of the averaged output increases as DT decreases.

RESTART INPUT DATA

*DATABASE_BINARY

*DATABASE_BINARY_OPTION

Options for binary output files with the default names given include:

- D3PLOT** Dt for complete output states.
- D3THDT** Dt for time history data for element subsets.
- D3DUMP** Binary output restart files. Define output frequency in cycles
- RUNRSF** Binary output restart file. Define output frequency in cycles.
- INTFOR** Dt for contact surface Interface database.

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---------|---|---|---|---|---|---|---|
| Variable | DT/CYCL | | | | | | | |
| Type | F | | | | | | | |

VARIABLE

DESCRIPTION

- DT Time interval between outputs.
EQ.0.0: Time interval remains unchanged.
- CYCL Output interval in time steps.
EQ.0.0: output interval remains unchanged.

DELETE*RESTART INPUT DATA*****DELETE_OPTION**

Available options are:

ALECPL
 CONTACT
 CONTACT_2DAUTO
 ENTITY
 PART
 ELEMENT_BEAM
 ELEMENT_SHELL
 ELEMENT_SOLID
 ELEMENT_TSHELL
 FSI

Purpose: Delete contact surfaces, ALE FSI couplings, parts, or elements by a list of IDs. There are two contact algorithms for two-dimensional problems: the line-to-line contact and the automatic contact defined by part IDs. Each uses their own numbering.

ID Cards. This card applies to the ALECPL, CONTACT, CONTACT_2DAUTO, ENTITY, FSI and PART options. Include as many cards as necessary to input desired IDs. This input ends at the next keyword ("*") card.

| Card 1a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|-----|-----|-----|-----|-----|-----|-----|-----|
| Variable | ID1 | ID2 | ID3 | ID4 | ID5 | ID6 | ID7 | ID8 |
| Type | I | I | I | I | I | I | I | I |

VARIABLE**DESCRIPTION**

IDn

Contact ID/Coupling ID/Part ID. See Remarks.

RESTART INPUT DATA

***DELETE**

Element Set Cards. This card applies to the four ELEMENT options. This input ends at the next keyword ("*") card.

| Card 1b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | ESID | | | | | | | |
| Type | I | | | | | | | |

VARIABLE

DESCRIPTION

ESID

Element set ID, see *SET_SOLID, *SET_BEAM, *SET_SHELL, *SET_TSHELL.

Remarks:

The FSI option corresponds to ALE couplings defined with *CONSTRAINED_LAGRANGE_IN_SOLID. The ALECPL option corresponds to ALE couplings defined with *ALE_COUPLING_NODAL_CONSTRAINT. For CONTACT, FSI, and ALECPL options, a negative ID implies that the absolute value gives the contact surface/FSI/ALECPL coupling which is to be activated.

***INTERFACE_SPRINGBACK_LSDYNA**

Purpose: Define a material subset for output to a stress initialization file dynain. The dynain file contains keyword commands that can be included in a subsequent input deck to initialize deformation, stress, and strain in parts. This file can be used, for example, to do an implicit springback analysis after an explicit forming analysis.

Part Set ID Cards.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|---|---|---|---|---|---|
| Variable | PSID | NSHV | | | | | | |
| Type | I | I | | | | | | |

Constraint Cards. Optional cards that list of nodal points that are constrained in the dynain file. This input ends at the next keyword ("**") card.

| Card 2 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|----|----|---|---|---|---|---|
| Variable | NID | TC | RC | | | | | |
| Type | I | F | F | | | | | |
| Default | none | 0. | 0. | | | | | |

VARIABLE**DESCRIPTION**

| | |
|------|--|
| PSID | Part set ID for springback, see *SET_PART. |
| NSHV | Number of shell or solid history variables (beyond the six stresses and effective plastic strain) to be initialized in the interface file. For solids, one additional state variable (initial volume) is also written. If NSHV is nonzero, the element formulations, calculational units, and constitutive models should not change between runs. If NHSV exceeds the number of integration point history variables required by the constitutive model, only the number required is written; therefore, if in doubt, set NHSV to a large number. |
| NID | Node ID |

| VARIABLE | DESCRIPTION |
|-----------------|---|
| TC | Translational constraint: EQ.0: no constraints, EQ.1: constrained x displacement, EQ.2: constrained y displacement, EQ.3: constrained z displacement, EQ.4: constrained x and y displacements, EQ.5: constrained y and z displacements, EQ.6: constrained z and x displacements, EQ.7: constrained x , y , and z displacements. |
| RC | Rotational constraint: EQ.0: no constraints, EQ.1: constrained x rotation, EQ.2: constrained y rotation, EQ.3: constrained z rotation, EQ.4: constrained x and y rotations, EQ.5: constrained y and z rotations, EQ.6: constrained z and x rotations, EQ.7: constrained x , y , and z rotations. |

***RIGID_DEFORMABLE_OPTION**

Available options include:

CONTROL

D2R (Deformable to rigid part switch)

R2D (Rigid to deformable part switch)

Purpose: Define parts to be switched from rigid to deformable and deformable to rigid in a restart. It is only possible to switch parts on a restart if part switching was activated in the time zero analysis. See *DEFORMABLE_TO_RIGID for details of part switching.

RESTART INPUT DATA

*RIGID_DEFORMABLE_CONTROL

*RIGID_DEFORMABLE_CONTROL

| Card | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|-----|-------|---|---|---|---|
| Variable | NRBF | NCSF | RWF | DTMAX | | | | |
| Type | I | I | I | F | | | | |
| Default | 0 | 0 | 0 | none | | | | |

VARIABLE

DESCRIPTION

| | |
|-------|--|
| NRBF | Flag to delete or activate nodal rigid bodies (see Remark 1): EQ.0: no change, EQ.1: delete, EQ.2: activate. |
| NCSF | Flag to delete or activate nodal constraint set (see Remark 2): EQ.0: no change, EQ.1: delete, EQ.2: activate. |
| RWF | Flag to delete or activate rigid walls: EQ.0: no change, EQ.1: delete, EQ.2: activate. |
| DTMAX | Maximum permitted time step size after restart. |

Remarks:

1. **Nodal Rigid Bodies.** If nodal rigid bodies or generalized, weld definitions are active in the deformable bodies that are switched to rigid, then the definitions should be deleted to avoid instabilities.
2. **Nodal Constraint Set.** If nodal constraint/spot weld definitions are active in the deformable bodies that are switched to rigid, then the definitions should be deleted to avoid instabilities.

*RIGID_DEFORMABLE_D2R

Part ID Cards. Include one card for each part. This input ends at the next keyword ("**") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|-----|---|---|---|---|---|---|
| Variable | PID | MRB | | | | | | |
| Type | I | I | | | | | | |
| Default | none | 0 | | | | | | |

VARIABLE

DESCRIPTION

- PID Part ID of the part which is switched to a rigid material.
- MRB Part ID of the master rigid body to which the part is merged. If zero, the part becomes either an independent or master rigid body.

RESTART INPUT DATA

*RIGID_DEFORMABLE_R2D

*RIGID_DEFORMABLE_R2D

Termination of this input is when the next "*" card is read.

Part ID Cards. Include one card for each part. This input ends at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|---|---|---|---|---|---|---|
| Variable | PID | | | | | | | |
| Type | I | | | | | | | |
| Default | none | | | | | | | |

VARIABLE

DESCRIPTION

PID

Part ID of the part which is switched to a deformable material.

***STRESS_INITIALIZATION_{OPTION}**

This keyword causes a full deck restart. For a full deck restart the input deck must contain the full model. The stress initialization feature allows all or selected parts to be initialized from the previous calculation using data from the d3dump or runrsf databases.

The options that are available with this keyword are:

<BLANK>

DISCRETE

SEATBELT

Optional Part Cards. If no part cards are included in the deck then all parts, seatbelts and discrete parts in the new input deck that existed in the previous input deck (with or without the same part IDs) are initialized from the d3dump or runrsf database. Otherwise for each part to be initialized from the restart data include an addition card in format 1. This input terminates at the next keyword ("*") card.

| Card 1 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|------|------|---|---|---|---|---|---|
| Variable | PIDO | PIDN | | | | | | |
| Type | I | I | | | | | | |
| Default | none | PIDO | | | | | | |

VARIABLE**DESCRIPTION**

| | |
|------|--|
| PIDO | Old part ID, see *PART. |
| PIDN | New part ID, see *PART: EQ.0: New part ID is the same as the old part ID. |

Remarks:

If one or more of the above cards are defined, then discrete and seatbelt elements will not be initialized unless the additional option cards *STRESS_INITIALIZATION_DISCRETE and *STRESS_INITIALIZATION_SEATBELT are defined.

*STRESS_INITIALIZATION_DISCRETE

RESTART INPUT DATA

***STRESS_INITIALIZATION**

Initialize all discrete parts from the old parts. No further input is required with this card. This card is not required if *STRESS_INITIALIZATION is specified without further input.

***STRESS_INITIALIZATION_SEATBELT**

Initialize all seatbelt parts from the old parts. No further input is required with this card. This card is not required if *STRESS_INITIALIZATION is specified without further input.

***TERMINATION_OPTION**

Purpose: Stops the job depending on some displacement conditions.

Available options include:

NODE

BODY

Caution: The inputs are different for the nodal and rigid body stop conditions. The nodal stop condition works on the global coordinate position, while the body stop condition works on the relative global translation. The number of termination conditions cannot exceed the maximum of 10 or the number specified in the original analysis.

The analysis terminates for *TERMINATION_NODE when the current position of the node specified reaches either the maximum or minimum value (stops 1, 2 or 3), or picks up force from any contact surface (stop 4). For *TERMINATION_BODY the analysis terminates when the center of mass displacement of the rigid body specified reaches either the maximum or minimum value (stops 1, 2 or 3) or the displacement magnitude of the center of mass is exceeded (stop 4). If more than one condition is input, the analysis stops when any of the conditions is satisfied.

NOTE: This input completely overrides the existing termination conditions defined in the time zero run.

Termination by other means is controlled by the *CONTROL_TERMINATION control card.

Card Summary:

Card 1a. This card is included if and only if the NODE keyword option is used.

| | | | | | | | |
|-----|------|------|------|--|--|--|--|
| NID | STOP | MAXC | MINC | | | | |
|-----|------|------|------|--|--|--|--|

Card 1b. This card is included if and only if the BODY keyword option is used.

| | | | | | | | |
|-----|------|------|------|--|--|--|--|
| PID | STOP | MAXC | MINC | | | | |
|-----|------|------|------|--|--|--|--|

RESTART INPUT DATA

*TERMINATION

Data Card Descriptions:

Node Cards. Include an additional card for each node with a termination criterion.

| Card 1a | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---------|------|------|------|---|---|---|---|
| Variable | NID/PID | STOP | MAXC | MINC | | | | |
| Type | I | I | F | F | | | | |
| Default | none | none | ↓ | ↓ | | | | |

VARIABLE

DESCRIPTION

| | |
|------|--|
| NID | Node ID |
| STOP | Stop criterion: EQ.1: global <i>x</i> direction, EQ.2: global <i>y</i> direction, EQ.3: global <i>z</i> direction, EQ.4: stop if node touches contact surface. |
| MAXC | Maximum (most positive) coordinate, options 1, 2 and 3 above only. |
| MINC | Minimum (most negative) coordinate, options 1, 2 and 3 above only. |

Part Cards. Include an additional card for each part with a termination criterion.

| Card 1b | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|----------|---------|------|------|------|---|---|---|---|
| Variable | NID/PID | STOP | MAXC | MINC | | | | |
| Type | I | I | F | F | | | | |
| Default | none | none | ↓ | ↓ | | | | |

VARIABLE

DESCRIPTION

| | |
|-----|-----------------------|
| PID | Part ID of rigid body |
|-----|-----------------------|

| VARIABLE | DESCRIPTION |
|-----------------|--|
| STOP | Stop criterion: EQ.1: global x -direction, EQ.2: global y -direction, EQ.3: global z -direction, EQ.4: stop if displacement magnitude is exceeded. |
| MAXC | Maximum (most positive) displacement, options 1, 2, 3 and 4: EQ.0.0: MAXC set to 10^{21} |
| MINC | Minimum (most negative) displacement, options 1, 2 and 3 above only: EQ.0.0: MINC set to -10^{21} |

APPENDIX A: User Defined Materials

Getting Started with User Defined Features

As a way of entering the topic, we begin by giving a general introduction to User Defined Features (*UDF*) in general. This section is supposed to be valid for any UDF described in the remaining appendices and serves as a practical guide to get to the point where technical coding may commence. For a comprehensive overview of UDFs and its applications, please refer to Erhart [2010] which can be seen as a complement to the present text.

Download

The first thing to do is to download an *object version* of LS-DYNA for the computer architecture/platform of interest. This is a compressed package (.tgz,.tar.gz,.zip) provided by your local LS-DYNA distributor whose unpacked content is not only a single binary executable but a *usermat* directory possibly including

- precompiled static object libraries (.a, .lib)
- fortran source code files (.f, .F)
- include files (.inc)
- makefile

It is important to know what version to download, i.e., a version that is compatible with your computer environment in terms of architecture, operating system and possible MPI implementation in case of MPP. This may not be obvious to all users and for questions regarding this we refer to your LS-DYNA distributor. An object version does not require a special license but goes under the general LS-DYNA license agreement. The picture above gives a conceptual overview of the usermat package, and at this point

APPENDIX A

we need to mention that presence of libraries and include files are made obsolete with the advent of modules as to be explained below, but we start with the non-modular approach.

Static or Dynamic linking

To get something that is actually runnable it is necessary to *compile* the source code files and link the resulting object files either to a *shared object* (.so, .dll) or with the precompiled libraries to a binary executable. The former option requires a shared object version of the usermat package while the latter assumes a statically linked version, and this is thus a choice that needs to be made before retrieving the package. Working with shared objects is more flexible in the sense that a binary executable can be installed once and for all and the (small) shared object is dynamically linked at runtime as a plugin. Upon execution, LS-DYNA will look for the shared object file in directories specified by a library path that is usually set/edited in the run command script, and when found the shared object content is linked to the execution. On Linux OS's this is for instance governed by the environment variable LD_LIBRARY_PATH. The shared object is easily substituted or the run command script can be edited to redirect the location of the shared object, and this facilitates portability when working on large projects. A statically linked version requires that the entire binary executable is generated at compile time and this option may be preferred if working on small projects or during the development phase.

Compiler and Compiling

The compilation is usually performed in the usermat (working) directory using a terminal window. The object version does not contain a compiler but it is assumed that the appropriate compiler is installed on your system and accessible from your working directory. To render compatibility between the precompiled libraries or binary executable and your compiled object files, the *appropriate* compiler is the (by LSTC) designated compiler with which the precompiled libraries or binary are readily compiled. As examples, on Linux this is typically either the Intel Fortran Compiler (IFC) on Red Hat or CentOS or Portland Groups Compiler (PGF) on SUSE, and on Windows it is the Intel Fortran Compiler (IFC) in combination with Microsoft Visual Studio (MSVS). For MPP you also need a wrapper for whatever MPI implementation you have installed, but again, consult your LS-DYNA distributor for detailed information.

To compile, execute 'make' in the terminal window and in most cases this will generate a shared object or binary executable depending on your type of LS-DYNA object version, and if not it comes down to interpreting error messages. A possible reason for failure is that the makefile that comes with the usermat package does not contain appropriate compiler directives and requires some editing. This could range from trivial tasks like altering the path used to actually find the compiler on your system to more complex endeavors such as adding or changing compiler flags. An even worse scenario is that your operating system is not up-to-date and may require that the library content on your computer is somehow updated. Whatever the reason might be, any

case is unique and the situation is preferably resolved by your computer administrator in collaboration with your LS-DYNA distributor.

Execution

When compiling a virgin instance of an object version, the generated executable *{xyz}dyna* in combination with a possible shared object *lib{xyz}dyna_{t}_{Y}.{Z}.so* makes up an exact replica of a non-object executable counterpart. It is only when the source code is modified that a customized version is generated. In the adopted binary and shared object naming convention above, *xyz* stands for *smp* or *mpp*, *t* is either *s* for single precision or *d* for double precision, *Y* is the base revision number for the LS-DYNA and *Z* is the corresponding release revision number. *Z* is always larger than *Y*. The binary and shared object may be left in the working directory, moved to some other location on your system or properly installed for execution on clusters by a queuing system. Obviously the way execution is performed is affected accordingly, and we don't claim to cover all these situations but leave this task to you and your computer administrator. While the executable may be renamed, a shared object should in general not be since this dynamic dependence is built into the executable. During the development phase it may be convenient to leave the binary in its place to facilitate debugging, but possibly move the shared object to the execution directory to not having to edit the library path for the executable to find it. Two Linux examples on how to run an input file are given in the following, one assuming an SMP static object version has been downloaded and the other an MPP shared object version. Let */path_to_my_source/usermat* be the complete path to the working directory and *in.k* be the name of the LS-DYNA keyword input file. If located in the *execution* directory, i.e., the directory containing *in.k*, the problem is run as

```
/path_to_my_source/usermat/lsdyna i = in.k
```

in the SMP case. For the MPP shared object case, you may copy the shared object file to the execution directory which is a default directory for executables to look for dynamic object files. Assuming the MPI software is platform-MPI, the input file could be run on 2 cores as

```
/path_to_platform-mpi/bin/mpirun -np 2 /path_to_my_source/usermat/mppdyna i = in.k
```

These two examples are only intended to indicate how to treat the compiled files and changes in details thereof are to be expected.

Coding

All subroutines for the UDFs are collected in the files *dyn21.f* and *dyn21b.f* and are ready for editing using your favorite text editor. Mechanical user materials, user defined loading, user defined wear and friction are contained in *dyn21.f*, while user defined elements and thermal user materials are in *dyn21b.f*, just to give a few examples. The prevailing programming language is Fortran 77, but many compilers support Fortran 90

APPENDIX A

and it may also be possible to write C code but this requires some manipulation of the makefile and function interfaces. Each individual feature is connected to one or a few keywords to properly take advantage of innovative coding. For user materials, this keyword is `*MAT_USER_DEFINED_MATERIAL_MODELS` and is described in detail below, and for user defined loads the corresponding keyword is `*USER_LOADING`. We refer to the individual keyword sections for details on their respective usage.

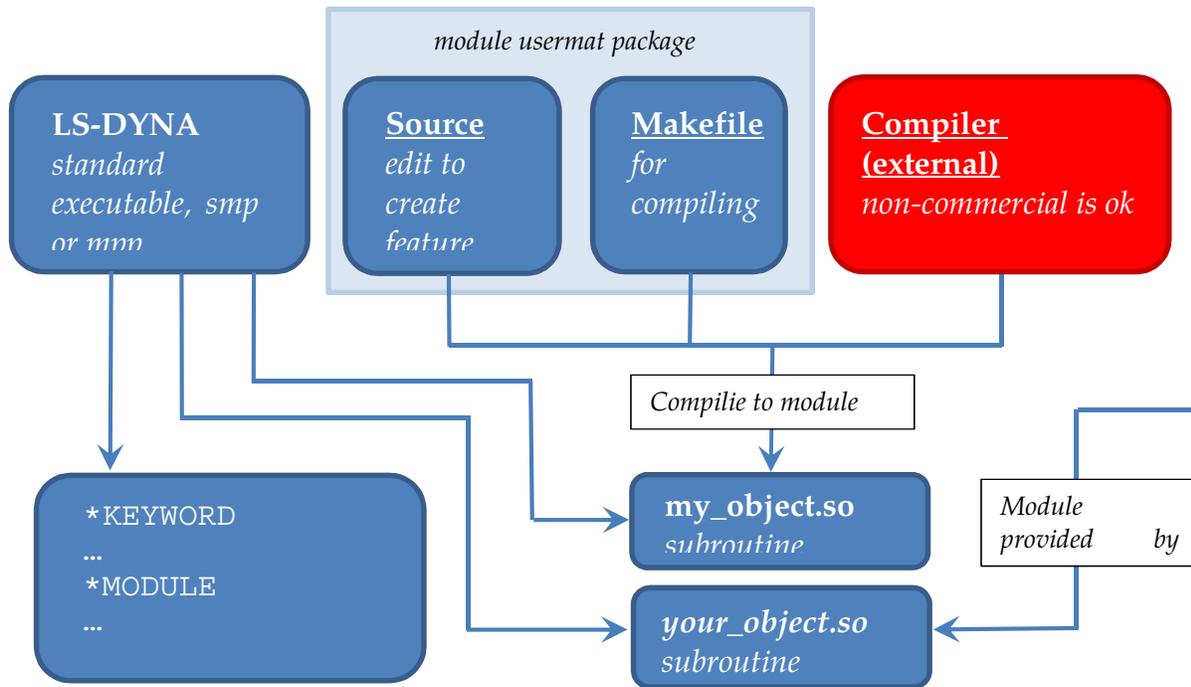

Module Concept

As of version R9 of LS-DYNA (MPP only), there is yet another way of approaching user defined features, namely through the concept of *modules*. The purpose is twofold;

- 1.To facilitate working with UDFs in that the content of the usermat package is significantly reduced and instead replaced by `*MODULE` keywords
- 2.To enhance flexibility when incorporating features delivered as shared objects by third parties

By way of [1](#), the usermat package only consists of a makefile and a few source code files, and in principle all the user needs to do is to *(i)* implement the feature of interest in the source code files, *(ii)* compile to a shared object using the makefile, and *(iii)* use the keyword input file to access the generated object. A shared object to be used in this way is henceforth called a *module*. One of two nice side effects coming out of this approach is that the restriction on the choice of compiler is alleviated, the source code files can be compiled with any valid fortran compiler as long as the generated module is linkable as a plug-in to LS-DYNA. The other is that the LS-DYNA executable need not be updated as new versions of the *module usermat package* is retrieved, the plug-in concept should still work¹. To explain how LS-DYNA in practice access modulus and specific routines therein, and at the same time address [2](#) above, the `*MODULE` keyword requires some attention by means of an example.

¹ Currently a special “module” version is required to work with this approach, contact your local distributor for details.

In a standard version of LS-DYNA the keywords

```
*MODULE_PATH
*MODULE_LOAD
*MODULE_USE
```

are available, see the Section on *MODULE for further explanations than what is provided here. With reference to the picture above, we assume that *my_object.so* and *your_object.so* are two independently generated modules, and both are located in directory */path_to_modules*. We also assume that these two objects contain the same routines names, one of them being the source code for user material 41 (*subroutine umat41*). Without the present approach, it would be at least intricate to execute both of these two source codes in the same LS-DYNA executable and same keyword input. A simple way of dealing with this here is to use the following set of keywords

```
*MODULE_PATH
/path_to_modules
*MODULE_LOAD
$ MDLID          TITLE
myid             my library
$ FILENAME
my_object.so
*MODULE_LOAD
$ MDLID          TITLE
yourid          your library
$ FILENAME
your_object.so
*MODULE_USE
$ MDLID
```

APPENDIX A

```
myid
$ TYPE          PARAM1          PARAM2
UMAT            1001            41
*MODULE_USE
$ MDLID
yourid
$ TYPE          PARAM1          PARAM2
UMAT            1002            41
*MAT_USER_DEFINED_MATERIAL_MODELS
$      MID      RO      MT
          1      7.85e-9      1001
...
*MAT_USER_DEFINED_MATERIAL_MODELS
$      MID      RO      MT
          2      7.85e-9      1002
...
*PART
first part
$      PID      SECID      MID
          1          1          1
*PART
second part
$      PID      SECID      MID
          2          2          2
```

The `*MODULE_PATH` lists the path(s) to the modules to be loaded, `*MODULE_LOAD` actually loads the module into LS-DYNA, and `*MODULE_USE` tells LS-DYNA how to access routines in the module. In this particular example, the rules (`TYPE = UMAT`) are that a user material `*MAT_USER_...` with `MT` set to 1001 (because `PARAM1 = 1001`) will execute subroutine `umat41` (because `PARAM2 = 41`) in the module with id `myid` (because `MDLID = myid`) and in the same manner user material with `MT` set to 1002 will also execute subroutine `umat41` but now in the module with id `yourid`. Hence we have made part 1 and part 2, in the same keyword input file, execute the *same* subroutine (by name) but in *different* modules. Obviously this generalizes to any number of modules by analogy, see `*MODULE_USE` for many more rules and yet another example.

General overview

We now turn to the specific documentation of user defined materials. Up to ten user subroutines can currently be implemented simultaneously to update the stresses in solids, shells, beams, discrete beams and truss beams. This text serves as an introductory guide to implement such a model. Note that names of variables and subroutines below may differ from the actual ones depending on platform and current version of LS-DYNA.

When the keyword `*MAT_USER_DEFINED_MATERIAL_MODELS` is defined for a part in the keyword deck, LS-DYNA calls the subroutine `usrmat` with appropriate input data

for the constitutive update. This routine in turn calls `urmathn` for 2D and 3D solid elements, `urmats` for 2D plane stress and 3D shell elements, `urmatb` for beam elements, `urmatd` for discrete beam elements and `urmatt` for truss beam elements. In these routines, which may be modified by the user if necessary, the following data structures are initialized for the purpose of being supplied to a specific *scalar* material subroutine.

- `sig(6)` - stresses in previous time step
- `eps(6)` - strain increments
- `epsp` - effective plastic strain in previous time step
- `hsv(*)` - history variables in previous time step excluding plastic strain
- `dt1` - current time step size
- `temper` - current temperature
- `failel` - flag indicating failure of element

If the *vectorization* flag is active (`IVECT = 1`) on the material card, variables are in general stored in vector blocks of length `nlq`, with vector indexes ranging from `lft` to `llt`, which allows for a more efficient execution of the material routine. As an example, the data structures mentioned above are for the vectorized case exchanged for

- `sigX(nlq)` - stresses in previous time step
- `dX(nlq)` - strain increments
- `epsps(nlq)` - effective plastic strains in previous time step
- `hsvs(nlq,*)` - history variables in previous time step
- `dtlsiz(nlq)` - current time step sizes
- `temps(nlq)` - current temperatures
- `failels(nlq)` - flags indicating failure of elements

where *X* ranges from 1 to 6 for the different components. Each entry in a vector block is associated with an element in the finite element mesh for a fix integration point.

The number of entries in the history variables array (indicated by *** in the above) matches the number of history variables requested on the material card (`NHV`). Hence the number `NHV` should equal to the number of history variables excluding the effective plastic strain since this variable is given a special treatment. All history variables, including the effective plastic strain, are initially zero. Furthermore, all user-defined material models require a bulk modulus and shear modulus for transmitting boundaries, contact interfaces, rigid body constraints, and time step calculations. This generally means that the length of material constants array `LMC` must be increased by 2 for the storage of these parameters. In addition to the variables mentioned above, the following data can be supplied to the user material routines, regardless of whether vectorization is used or not.

- `cm(*)` - material constants array
- `capa` - transverse shear correction factor for shell elements
- `tt` - current time

APPENDIX A

`crv(lq1,2,*)` - array representation of curves defined in the keyword deck

A specific material routine, `umatXX` in the scalar case or `umatXXv` in the vector case, is now called with any necessary parameters of the ones above, and possibly others as well. The letters `XX` stands for a number between 41 and 50 and matches the number `MT` on the material card. This subroutine is written by the user, and should update the stresses and history variables to the current time. For shells and beams it is also necessary to determine the strain increments in the directions of constrained zero stress. To be able to write different stress updates for different elements, the following character string is passed to the user-defined subroutine

`etype` - character string that equals `solid`, `shell`, `beam`, `dbeam` or `tbeam`

A sample user subroutine of a hypo-elastic material in the scalar case is provided below. This sample and the others below are from the `dyn21.F` file that is distributed with version R6.1.

Sample user subroutine 41

```
      subroutine umat41 (cm,eps,sig,epsp,hsv,dt1,capa,etype,tt,
1 temper,failel,crv,nnpcrv,cma,qmat,elsiz,idele,reject)

APPENDIX A

ADDITIONAL FEATURES

Load curves and tables

If the material of interest should require load curves, for instance a curve defining yield stress as a function of effective plastic strain, curve and table lookup are easily obtained by predefined routines.

The routines to be called are

```
subroutine crvval(crv,nnpcrv,eid,xval,yval,slope)
```

and

```
subroutine crvval_v(crv,nnpcrv,eid,xval,yval,slope,lft,llt)
```

where the former routine is used in the scalar context and the latter for vectorized umat.

The arguments are the following

- crv - the load curve array (available in material routine, just pass on)
- nnpcrv - curve data pointer (available in material routine, just pass on)
- eid - external load curve ID, i.e., the load curve ID taken from the keyword deck
 - .GT.0: Use approximate representation of curve
 - .LT.0: Use exact representation of curve (with id -eid)
- xval - abscissa value
- yval - ordinate value (output from routine)
- slope - slope of curve (output from routine)
- lft - first index of vector
- llt - final index of vector

where xval, yval and slope are scalars in the scalar routine and vectors of length nlg in the vectorized routine. Note that eid should be passed as float. Using a positive number for eid will use the approximative representation of the curve, whereas if eid is a negative number the extraction will be made on the curve as it is defined in the keyword input deck.

For tables, two subroutines are available for extracting values. A scalar version is

```
subroutine tabval(crv,nnpcrv,eid,dxval,yval,dslope,xval,slope)
```

and a vector version is

```
subroutine  
1 tabval_v(crv,nnpcrv,eid,dxval,yval,dslope,lft,llt,xval,slope)
```

where

- crv - curve array (available in material routine, just pass on)
- nnpcrv - curve pointer (available in material routine, just pass on)

`eid` - external table id (data type real), i.e., table id taken from keyword deck
 GT.0: Use approximative representation of curve
 LT.0: Use exact representation of curve (with id `-eid`)
`dxval` - abscissa value (x2-axis)
 `yval` - ordinate value (y-axis, output from routine)
`dslope` - slope of curve (dy/dx_2 , output from routine)
 `xval` - abscissa value (x1-axis)
`slope` - slope of curve (dy/dx_1 , output from routine)
 `lft` - vector index
 `llt` - vector index

In the scalar routine, `dxval`, `yval`, `dslope`, `xval` and `slope` are all scalars whereas in the vector routine they are vectors of length `nlq`. Also here, using a positive number for `eid` will use the approximative representation of the table, whereas if `eid` is a negative number the extraction will be made on the table as it is defined in the keyword input deck.

Local coordinate system

If the material model has directional properties, such as composites and anisotropic plasticity models, the local coordinate system option can be invoked. This is done by putting `IORTHO` equal to 1 on the material card. This also requires two additional cards with values for how the coordinate system is formed and updated. When this option is used, all data passed to the constitutive routine `umatXX` or `umatXXv` is in the local system and the transformation back to the global system is done outside this user-defined routine. There is one exception however, see the section on the deformation gradient.

Temperature

For a material with thermal properties, temperatures are made available by putting the flag `ITHERMAL` equal to 1 on the material card. The temperatures in the elements are then available in the `temper` variable for a scalar and `temps` array for the vectorized implementation. For a coupled thermal structural analysis, the thermal problem is solved first and temperatures at the current time are available in the user-defined subroutine. Calculation of dissipated heat in the presence of plastic deformation is taken care of by LS-DYNA and needs not be considered by the user. If the time derivative of the temperature is needed for the stress update, a history variable that contains the temperature in the previous time step should be requested. The time derivative can then be obtained by a backward finite difference estimate.

APPENDIX A

Failure

It is possible to include failure in the material model, resulting in the deletion of elements that fulfill a certain failure criterion. To accomplish this, the flag `IFAIL` must be set to 1 or a negative number on the material card. For a scalar implementation, the variable `failel` is set to `.true.` when a failure criterion is met. For a vectorized implementation, the corresponding entry in the `failels` array is set to `.true.`

Deformation gradient

For some materials, the stresses are not obtained from incremental strains, but are expressed in terms of the deformation gradient F . This is the case for hyper-elastic(-plastic) materials. To make the deformation gradient available for bricks and shells in the user-defined material subroutines, the variable `IHYPER` on the material card should be set to 1. The deformation gradient components $F_{11}, F_{21}, F_{31}, F_{12}, F_{22}, F_{32}, F_{13}, F_{23}$ and F_{33} can then be found in the history variables array in positions `NHV+1` to `NHV+9`, i.e., the positions coming right after the requested number of history variables.

For shell elements, the components of the deformation gradient are with respect to the co-rotational system for the element currently used. In this case the third row of the deformation gradient, i.e., the components F_{31}, F_{32} and F_{33} , will not be properly updated when entering the user-defined material routine. These components depend on the thickness strain increment which in turn must be determined so that the normal stress in the shell vanishes. For a given thickness strain increment $d3$, these three components, `f31`, `f32` and `f33`, can be determined by calling the subroutine

```
subroutine compute_f3s(f31,f32,f33,d3)
```

for a scalar implementation and

```
subroutine compute_f3(f31,f32,f33,d3,lft,llt)
```

for a vector implementation. The first four arguments are arrays of length `nlq` for the vector routine and scalars for the scalar routine.

For hyper-elastic materials there are push forward operations that can be called from within the user defined subroutines. These are

```
subroutine push_forward_2(sig1,sig2,sig3,sig4,sig5,sig6,  
f11,f21,f31,f12,f22,f32,f13,f23,f33,lft,llt)
```

which performs a push forward operation on the stress tensor, and the corresponding scalar routine

```
subroutine push_forward_2s(sig1,sig2,sig3,sig4,sig5,sig6,  
f11,f21,f31,f12,f22,f32,f13,f23,f33)
```

In the latter subroutine all arguments are scalars whereas the corresponding entries in the vectorized routine are vectors of length `nlq`. The `sig1` to `sig6` are components of the stress tensor and `f11` to `f33` are components of the deformation gradient.

If the local coordinate system option is invoked (IORTHO = 1), then the deformation gradient is transformed to this local system prior to entering the user-defined material routine according to

$$\bar{F}_{ij} = Q_{ki}^s F_{kj}$$

where Q_{ij}^s refers to a transformation between the current global and material frames. For IORTHO equal to 1 one can choose to put IHYPER equal to -1 which results in that the deformation gradient is transformed according to

$$\bar{F}_{ij} = F_{ik} Q_{kj}^r$$

where Q_{ij}^r is the transformation between the reference global and material and frames. For this latter option the spatial frame remains the global one so the stresses should be expressed in this frame of reference upon exiting the user defined routines. The suitable choice of IHYPER depends on the formulation of the material model.

For shells, there is also the special option of setting IHYPER = 3 which will make the deformation gradient computed from the nodal coordinates and in the global coordinate system. With this option the user must compute the stress in the local system of interest, whence a transformation matrix between the global and this local system is passed to the user material routines (qmat). The columns in this matrix correspond to local basis vectors expressed in global coordinates, and this is the system that stress needs to be computed in. The user must be aware that since the deformation gradient is calculated directly from the element deformation it may not be consistent with the theory of the element that is used for the material. To account for thickness changes due to membrane straining, there are routines

```
subroutine usrshl_updatfs(f,t,s,e)
  real f(3,3),t(4),s(4),e
```

that recompute the deformation gradient based on the thickness strain increment e , and the nodal thicknesses t . The current nodal thicknesses are stored in the history variables array immediately following the storage of the deformation gradient. This routine must be called with these four values as t . This subroutine is expected to produce a deformation f and the new thicknesses s . This routine is used to find the strain increment e giving zero thickness stress. Once zero thickness stress is obtained, the user needs to store the new thicknesses s in the history variables array, which is achieved by copying the new thicknesses s to the location for the nodal thicknesses. There is also a vectorized version of this routine called `usrshl_updatfv`. Sample code is provided in the object library.

In the following, a Neo-Hookean material is used as an example of the usage of the deformation gradient in user-defined materials. With λ and μ being the Lamé parameters in the linearized theory, the strain energy density for this material is given by

APPENDIX A

$$\psi = \frac{1}{2}\lambda(\ln(\det\mathbf{F}))^2 - \mu\ln(\det\mathbf{F}) + \frac{1}{2}\mu(\text{tr}(\mathbf{F}^T\mathbf{F}) - 3)$$

meaning that the Cauchy stress can be expressed as

$$\boldsymbol{\sigma} = \frac{1}{\det\mathbf{F}} (\lambda\ln(\det\mathbf{F})\mathbf{I} + \mu(\mathbf{F}\mathbf{F}^T - \mathbf{I})).$$

Implicit analysis

For brick, and shell, thick shell and Hughes-Liu beam elements, a user-defined material model can also be run with implicit analysis. When an implicit analysis is requested in the input keyword deck, LS-DYNA calls the subroutine `urtanh` for bricks, `urtans` for shells and `urtanb` for beams with appropriate input data for the calculation of the material tangent modulus. For a scalar implementation, this routine in turn calls `utanXX` with all necessary input parameters including

`es(6,6)` - material tangent modulus

Again, `XX` is the number that matches `MT` on the material card. For a vectorized implementation, the routine `utanXXv` is called, this time with the corresponding vector block

`dsave(nlq,6,6)` - material tangent modulus

This subroutine builds the tangent modulus to be used for assembling the tangent stiffness matrix and must be provided by the user. This matrix is equal to the zero matrix when entering the user-defined routine, it must be symmetric and if the local

APPENDIX A

coordinate system option is invoked for bricks, then it should be expressed in this local system. For shell elements, it should be expressed in the co-rotational system defined for the current shell element. All transformations back to the global system are made after exiting the user-defined routine.

A feature that can be made useful for improving convergence characteristics is the parameter `reject`, which can be set to `.true.` in the user material routine. The purpose of this parameter is to indicate *something* that renders the iteration unacceptable. An example of this something may be too much increase in plastic strain in one step, another is a criterion on the total strain increment. What LS-DYNA will do in this situation is to print a warning message 'Material model rejected current iterate' and retry the step with a smaller time step. If chosen carefully (by way of experimenting), this may result in a good trade-off between the number of implicit iterations per step and the step size for overall speed.

If the material is hyper-elastic, there are push forward operations of tangent modulus tensor available in

```
subroutine push_forward_4(dsave,  
    f11, f21, f31, f12, f22, f32, f13, f23, f33, lft, llt)
```

which performs a push forward operation on the tangent modulus tensor, and the corresponding scalar routine

```
subroutine push_forward_4s(es,  
    f11, f21, f31, f12, f22, f32, f13, f23, f33)
```

In the latter subroutine all arguments are scalars whereas the corresponding entries in the vectorized routine are vectors of length `n1q`. The `f11` to `f33` are components of the deformation gradient.

The following sample user subroutine illustrates how to implement the tangent stiffness modulus for the Neo-Hookean material above. The material tangent modulus is for this material given by

$$\mathbf{C} = \frac{1}{\det\mathbf{F}} (\lambda \mathbf{I} \otimes \mathbf{I} + 2(\mu - \lambda \ln(\det\mathbf{F}))\mathbf{I}).$$

Sample user subroutine 42, tangent modulus

```
subroutine utan42(cm,eps,sig,eps,hsv,dt1,capa,  
    .    etype,tt,temper,es,crv)

User-Defined Materials with Equations of State

The following example `umat44v` is set up to be used with an equation of state (EOS). Unlike standard models, it updates only the deviatoric stress and it assigns a value to *PC*, the pressure cut-off. The pressure cut-off limits the amount of hydrostatic pressure that can be carried in tension (i.e., when the pressure is negative). The default value is zero, and a large negative number will allow the material to carry an unlimited pressure load in tension. It is calculated within the material model because it is typically a function of the current state of the material and varies with time. In this example, however, it is a constant value for simplicity. The pressure cut-off array is passed through the named common block `eosdloc`. Depending on the computing environment, compiler directives may be required (e.g., the `task common` directive in the example) for correct SMP execution.

In addition, the number of history variables, *NHV*, must be increased by 4 in the input file to allocate the extra storage required for the EOS. The storage is the first 4 variables in `hsvs`, and it must not be altered by the user-defined material model.

Post-processing a user-defined material

Post-processing a user-defined material is very similar to post-processing a regular LS-DYNA material. There are however some things that are worth being stressed, all dealing with how to post-process history variables.

APPENDIX A

First, the effective plastic strain is always written to the d3plot database and thus need not be requested by the user. It is in LS-PRE/POST treated just as it is for any other LS-DYNA material.

The number of additional history variables written to the d3plot database must be requested as the parameter NEIPH (for bricks) or NEIPS (for shells) on *DATABASE_EXTENT_BINARY. For instance, if NEIPH (NEIPS) equals 2 the first two history variables in the history variables array are obtained as history var#1 and history var#2 in the d3plot database. By putting NEIPH (NEIPS) equal to NHV, all history variables are written to the d3plot database. Furthermore, if the material uses the deformation gradient (IHYPER = 1) an additional 9 variables must be requested to make this available for post-processing, i.e., put NEIPH (NEIPS) equal to NHV+9. This makes the deformation gradient available in the d3plot database as history variables NHV+1 to NHV+9, note however that for shells it is expressed in the co-rotational system. If the local coordinate system option (IORTHO = 1) is used, then the deformation gradient is expressed in this local system. To make the deformation gradient in the global system for bricks and co-rotational system for shells available and stored as history variables NHV+10 to NHV+18, NEIPH (NEIPS) is put equal to NHV+9+9 (=NHV+18).

APPENDIX B:

User Defined Equation of State

The user can supply his/her own subroutines defining equation of state (EOS) models in LS-DYNA. To invoke a user-defined EOS, one must

1. Write a user EOS subroutine that is called by the LS-DYNA user EOS interface.
2. Create a custom executable which includes the EOS subroutine.
3. Invoke that subroutine by defining a part in the keyword input deck that uses `*EOS_USER_DEFINED` with the appropriate input parameters.

Subroutine `ueoslib` and sample subroutines `ueos21s` and `ueos21v` are provided in the file `dyn21b.f`. This text serves as an introductory guide to implementing such a model. Note that names of variables and subroutines below may differ from the actual ones depending on platform and current version of LS-DYNA.

General overview

When the keyword `*EOS_USER_DEFINED` is defined for a part in the keyword deck, LS-DYNA calls the subroutine `ueoslib` with the appropriate input data for the EOS update. This subroutine is called twice for each integration point in each element. The first call requires the EOS to calculate the bulk modulus, and the second updates the pressure and internal energy. In these routines, which may be modified by the user if necessary, the following data structures are initialized for the purpose of being supplied to a specific *scalar* material subroutine.

```

iflag - mode flag
        EQ.-1: for initializing EOS constants
        EQ.0: for calculating the bulk modulus
        EQ.1: for the pressure and energy update
cb - bulk modulus
pnew - the new pressure
rho0 - reference density
hist - array of user-defined history variables NHV in length
specen - internal energy per unit reference volume
df - volume ratio,  $V/V_0$ 
v0 - the initial volume.
dvol - volume increment
pc - pressure cut-off

```

APPENDIX B

If the *vectorization* flag is active (`IVECT = 1`) on the EOS card, variables are, in general, stored in vector blocks of length `nlq`, with vector indices ranging from `lft` to `llt`, which allows for a more efficient execution of the EOS routine. As an example, the data structures mentioned above for the vectorized case are

- `cb(nlq)` - bulk modulus
- `pnew(nlq)` - the new pressure
- `hist(nlq,*)` - array of user-defined history variables with NHV columns
- `specen(nlq)` - internal energy per unit reference volume
- `df(nlq)` - volume ratio, V/V_0
- `v0(nlq)` - the initial volume
- `dvol(nlq)` - volume increment
- `pc(nlq)` - pressure cut-off

The value of `nlq` is set as a parameter in the include file `nlqparm`, included at the top of the subroutine, and varies between machines and operating systems. Each entry in a vector block is associated with an element in the finite element mesh for a fix integration point. The number of entries in the history variables array (indicated by `*` in the above) matches the number of history variables requested on the material card (NHV). All history variables are initially zero and are initialized within the EOS on the first time step, when the logical variable `first`, passed through the argument list, is `.TRUE`. Furthermore, all user-defined EOS models require a bulk modulus, `cb`, for transmitting boundaries, contact interfaces, rigid body constraints, and time step calculations. In addition to the variables mentioned above, the following data can be supplied to the user material routines, regardless of whether vectorization is used or not.

- `eosp(*)` - array of material constants from the input file
- `tt` - current time
- `crv(lq1,2,*)` - array representation of curves defined in the keyword deck.

A user defined EOS subroutine, `ueosXXs` in the scalar case or `ueosXXv` in the vector case, will be called for parts that point to `*EOS_USER_DEFINED` in the input deck. The letters `XX` stand for a number between 21 and 30 that matches the input variable `EOST` in the `*EOS_USER_DEFINED` keyword. During the initialization phase, the EOS is called with `iflag = -1` to permit the initialization of constants in the user EOS. Although fewer than 48 constants may be read into the array `eosp` during the input, the user may use all 48 within the EOS subroutines. The user defined subroutine should calculate the bulk modulus when `iflag = 0`, and update the pressure, internal energy and history variables when `iflag = 1`.

The use of curves (`*DEFINE_CURVE`) is discussed in Appendix A.

A sample scalar user subroutine for a Gruneisen EOS is provided below and it is immediately followed by its vector counterpart.

Sample user subroutine 21

```

The Gruneisen EOS implemented in the example subroutines has the same form as *EOS_GRUNEISEN, EOS Form 4. Its update of the pressure and the internal energy are typical for an EOS that is linear in the internal energy,

$$P = A(\rho) + B(\rho)E$$

where A and B correspond to the variables a and b in the example subroutines, and E is $specen$. Integrating the energy equation with the trapezoidal rule gives

$$E^{n+1} = E^n + \frac{1}{2}(\sigma'^n + \sigma'^{n+1})\Delta\varepsilon - \frac{1}{2}(P^n + q^n + P^{n+1} + q^{n+1})\frac{\Delta V}{V_0}$$

where the superscripts refer to the time step, ΔV is the change in the volume associated with the Gauss point and V_0 is the reference volume. Collecting all the energy contributions on the right hand side except for the contribution from the new pressure gives a simple linear relationship between the new internal energy and pressure,

$$E^{n+1} = \tilde{E} - \frac{P^{n+1}\Delta V}{2V_0}.$$

APPENDIX B

The value of `specen` passed to `ueosXX` for the pressure and energy update corresponds to \tilde{E} . Substituting this relation into the EOS and solving for the new pressure gives

$$P^{n+1} = \frac{A\rho^{n+1} + B\rho^{n+1}\tilde{E}}{1 + \frac{B\Delta V}{2V_0}}.$$

The final update of the new energy is calculated using the new pressure. For a more general EOS, the nonlinear equation in the new pressure,

$$P^{n+1} = P\left(\rho^{n+1}, \tilde{E} - \frac{P^{n+1}\Delta V}{2V_0}\right)$$

is solved iteratively using Newton iteration or successive substitution.

The pressure cut-off, `pc`, is used to limited the amount of pressure that can be generated by tensile loading, `pnew=max(pnew, pc)`. Its value is usually specified in the `*MAT` input, e.g., `*MAT_JOHNSON_COOK`. It is not enforced outside of the EOS subroutines, and it is up to the user to determine whether or not to enforce the pressure cut-off in `ueosXX`. If the user does enforce it, the pressure cut-off should be applied before the final update to the internal energy otherwise the energy will be incorrect.

Many of the calculations performed to calculate the bulk modulus are the same as those for updating the pressure and energy. Since the bulk modulus calculation always precedes the pressure update, the values may be saved in a `common` block during the bulk modulus calculation to reduce the cost of the pressure update. The arrays used to store the values in the vectorized subroutines should be dimensioned by `n1q`.

One of the most common errors in implementing an EOS from a paper or book is the use of the wrong internal energy. There are three internal energies in common use: the energy per unit mass, e_M , the energy per unit current volume, e_V , and the energy per unit reference volume, E . LS-DYNA always uses the energy per unit reference volume. Some useful relations for converting between EOS in the literature and the variables in LS-DYNA are

$$\begin{aligned} e_V &= E \frac{V_0}{V} = \frac{\text{specen}}{\text{df}} \\ e_M &= E \frac{V_0}{M} = \frac{\text{specen}}{\frac{\text{rho0}}{\text{rho0}}} \\ \rho &= \rho_0 \frac{V_0}{V} = \frac{\text{rho0}}{\text{df}} \end{aligned}$$

APPENDIX C: User Defined Element Interface for Solids and Shells

In this appendix the user-defined element interface for solids and shells is described. The interface can accommodate either an integrated or a resultant element. For the integrated element, the user needs to supply two matrices defining the kinematical properties of the element, and choose between using standard LS-DYNA hourglass stabilization, a user-defined stabilization, or no stabilization when zero energy modes are not present. The number and location of the integration points is arbitrary, i.e., user-defined. For the resultant/discrete element formulations, the force and stiffness assembly must also be implemented. History variables can be associated with the user defined elements. If desired, the element may utilize more than the conventional 3 (for bricks) and 6 (for shells) degrees-of-freedom per node.

The user element is implemented according to how standard elements are implemented in LS-DYNA with the exception that two user routines are called for setting up the matrices of interest. In the end, the gradient-displacement matrix B_{ijkK} is constructed with the property that

$$B_{ijkK}u_{kK} = \frac{\partial v_i}{\partial x_j}$$

where u_{kK} is the vector of velocity nodal degrees of freedom and the right hand side is the velocity gradient. Moreover, the determinant J of the jacobian matrix determining the mapping from the isoparametric to physical domain is needed for numerical integration. From these expressions, the strains are determined as the symmetric part of the velocity gradient and the spin as the corresponding antisymmetric part. The stresses are evaluated using the constitutive models in LS-DYNA and the internal forces are obtained from

$$f_{kK} = \int \sigma_{ij} B_{ijkK} dV$$

where σ_{ij} are the stresses. Furthermore, the geometric and material tangent stiffnesses are obtained through

$$K_{iljj}^{\text{mat}} = \int C_{klmn} B_{kliI} B_{mnjj} dV$$

and

$$K_{iljj}^{\text{geo}} = \int \sigma_{mn} B_{kmiI} B_{knjj} dV$$

where C_{klmn} is the tangent modulus for the material. The integrals are evaluated using user-defined quadrature using the determinant J .

APPENDIX C

For user-defined hourglass control, the user must provide the corresponding internal force and stiffness contribution in a separate user routine. There is also the option to provide the force and stiffness matrix directly for the entire element.

To invoke a user-defined element one must do the following:

1. Write user element subroutine that defines the kinematics or kinetics of the element.
2. Create a custom executable which includes these subroutines.
3. Invoke the element by specifying this on the corresponding *SECTION card.

The dummy subroutines for the user defined elements are provided to the user in a FORTRAN source file for you to modify along with the necessary object files to compile a new executable. Contact LSTC or your local distributor for information about how to obtain these files as well as what compiler/version to use for your specific platform. Up to five user elements can simultaneously be used for bricks and shells (i.e. a total of ten). This text serves as an introductory guide on how to implement such an element.

General overview

To activate a user-defined element, it is necessary to set ELFORM to a number between 101 and 105 on the *SECTION definition. By doing so, the kinematics of the elements in the corresponding part will be determined from calling the subroutine

```
subroutine uXXX_bYYY(bmtrx,gmtrx,gjac,...  
:  
dimension bmtrx(nlq,3,3,*),gmtrx(nlq,3,3),gjac(*)
```

where XXX is substituted for *shl* for a shell-section and *sld* for a solid-section and YYY is the number specified in position ELFORM. Depending on the choice of ITAJ in the input, the user should set the matrices as follows.

If ITAJ = 0, then set the isoparametric gradient-displacement matrix, represented by the array *bmtrx*, and jacobian matrix, represented by the array *gmtrx*. Here, the first index corresponds to the LS-DYNA block loop index where *nlq* is the block size. For a more convenient notation in the following, we assign a correspondence between the arrays *gmtrx* and *bmtrx* in the subroutines to matrices/tensors as follows

$$\begin{aligned} gmtrx(*,i,j) &= g_{ij} \\ bmtrx(*,i,j,k) &= b_{ijk} \end{aligned}$$

These matrices should be determined so that at the current integration point:

$$g_{ij} = \frac{\partial x_i}{\partial \xi_j}$$

$$b_{ijk}u_k = \frac{\partial v_i}{\partial \xi_j} \Delta t$$

In the above, summation over repeated indices is assumed. We use the following notation:

$x_i(\xi_1, \xi_2, \xi_3, t)$ = i^{th} component of the current position vector at the isoparametric coordinate (ξ_1, ξ_2, ξ_3) and time t .

$v_i(\xi_1, \xi_2, \xi_3, t)$ = i^{th} component of the velocity vector at the isoparametric coordinate (ξ_1, ξ_2, ξ_3) and time t .

Δt = current time step

u_k = k^{th} component of generalized local displacements

ξ_i = i^{th} component of the isoparametric coordinate ranging from -1.0 to 1.0

For shells, there is an option to get all variables in either the LS-DYNA local coordinate system (ILOD=0) or in the global coordinate system (ILOD=1). The matrix for the coordinate system transformation is also passed to the user routines where the columns represent the local unit base vectors. The resulting strains must always be in the local coordinate system for the constitutive evaluations. For no extra degrees of freedom (see below), the index k in the displacement expression is determined from the formula

$$k = n(m - 1) + d$$

where $n = 3$ if only translational degrees of freedom are present (typical for solids) and $n = 6$ if rotational degrees of freedom are present (typical for shells), m is the local node number ($m = 1, 2, \dots$) and d is the degree of freedom. The translational degrees of freedom correspond to $d \leq 3$ and the rotational degrees of freedom to $4 \leq d \leq 6$.

If ITAJ=1, the user should set up the physical gradient-displacement matrix, represented by the array `bmtx`, and jacobian determinant, represented by the array `gjac`. Again, we assign a correspondence between the arrays `gjac` and `bmtx` in the subroutines to matrices/tensors as follows

$$\begin{aligned} \text{gjac}(\ast) &- J \\ \text{bmtx}(\ast, i, j, k) &- b_{ijk} \end{aligned}$$

These matrices should be determined so that at the current integration point:

$$J = \det \frac{\partial x_i}{\partial \xi_j}$$

$$b_{ijk}u_k = \frac{\partial v_i}{\partial x_j} \Delta t$$

APPENDIX C

To be able to set up these matrices, a set of additional auxiliary variables are passed to the user element subroutines. These include the isoparametric coordinate, the element thickness, and the shape function values, and derivatives. Again, for shells these are expressed in either the local or global coordinate system depending on the user's choice. For more information on these variables, the user is referred to the comments in the subroutines.

The integrated elements can use up to a total of 100 integration points (in the plane for shells) at arbitrary locations. These must be specified in terms of isoparametric coordinates and weights following the first of the user-defined cards in the *SECTION_... input. The isoparametric coordinates should range from -1 to 1 and the weights should sum up to 4 for shells and 8 for solids.

It may be necessary to incorporate hourglass stabilization to suppress zero energy modes, this is done by putting IHGF.GT.0 in the input. For IHGF.EQ.1, the LS-DYNA hourglass routines are used automatically and for IHGF.EQ.2 or IHGF.EQ.3 the user must provide hourglass force and stiffness in a specific user-defined routine. If IHGF.EQ.3, physical stabilization becomes available since the resultant material tangent moduli are passed to the hourglass routine to provide the current membrane, bending and coupled membrane-bending stiffness of the material. With C_{ij} denoting the material tangent modulus in matrix form, the resultant tangent moduli are expressed as

$$\begin{aligned}\bar{C}_{ij}^0 &= \int C_{ij} dV && \text{(membrane)} \\ \bar{C}_{ij}^1 &= \int z^1 C_{ij} dV && \text{(membrane - bending)} \\ \bar{C}_{ij}^2 &= \int z^2 C_{ij} dV && \text{(bending)}\end{aligned}$$

where z is the thickness coordinate for shells. For solids, only the first resultant modulus is passed. In this case the array has 21 entries that correspond to the subdiagonal terms of the 6 by 6 resultant matrix. For the matrix index (i,j) in the material tangent modulus matrix, where $i \geq j$, the index I of the array passed to the routine is given by

$$I = i(i-1)/2 + j$$

i.e., the subdiagonal terms are stored row-wise in the array. For shells, all three moduli are passed in the local coordinate system where each array has 15 entries corresponding to the subdiagonal terms of the 5 by 5 resultant matrices. The through thickness direction is here eliminated from the plane stress assumption. The formula for the array indices transformation above holds. This subroutine is called

```
subroutine uXXX_eYYY(force,stiff,ndtot,...
:
dimension force(nlq,*),stiff(nlq,ndtot,*)
```

where again XXX and YYY should be substituted as described for the other subroutines in the above. The variables in the subroutine corresponds to the force and stiffness as

$$\begin{aligned} \text{force}(*,i) &- f_i \\ \text{stiff}(*,i,j) &- K_{ij} \end{aligned}$$

where the indices corresponds to node and degree of freedom numbers exactly as for the displacements. For shells the force and stiffness is set up in the local element system (ILOC=0) or global system (ILOC=1). The variable `ndtot` is the total number of degrees of freedom for the element. Passed to this subroutine are also the property parameters and history variables associated with the element. The values of the property parameters are defined in the input of a user-defined element. No more than 40 property parameters and 100 history variables can be used for each user-defined element. The history variables must be updated in this routine by the user.

Resultant/discrete elements

By putting `NIP(P)` equal to 0 in the input, a resultant/discrete element is assumed. For this option (which is incompatible with `IHGF.GT.0`) the user must provide force and stiffness in the same user-defined routine as for the user-defined hourglass control. This means that no material routine is called to update stresses and history variables, rather stresses and history variables are to be updated from within the user element routine.

Nevertheless, the user should define `*MAT_ELASTIC` as the material for the corresponding part with suitable values of the Young's modulus and Poisson's ratio. These material properties are used to calculate the time step and for determining contact stiffnesses. Again, property parameters and history variables are passed to the routine, and for shells also the thicknesses of the elements. For the shell thickness update option (`ISTUPD.GT.0` on `*CONTROL_SHELL`) it is up to the user to update the thicknesses in this routine. For this option, and this option only, the stiffness matrix assembled in the element routines can be input as nonsymmetric if `LCPACK=3` on `*CONTROL_IMPLICIT_SOLVER`, i.e., if the nonsymmetric solver is used to update the Newton iterates.

In what follows, a short description of the additional features associated with the user elements is given.

Nodal fiber vectors

If a user-defined shell element formulation uses the nodal fiber vectors, this must be specified by putting `IUNF=1` on the `*SECTION_SHELL` card. With this option the nodal fiber vectors are processed in the element routines and can be used as input for determining the b_{ijk} , g_{ij}/J , f_i and K_{ij} tensors/matrices in the user routines. If not, it is assumed that the fiber direction is normal to the plane of the shell at all times. These

APPENDIX C

are expressed in either the local or global system depending on the user's choice. See comments in the subroutines for more information.

Extra degrees of freedom

Exotic element formulations may require extra degrees-of-freedom per node besides the translational (and rotational) degrees-of-freedom. Currently, up to 3 extra degrees of freedom per node can be used for user-defined elements. To use extra degrees of freedom, a scalar node must be defined for each node that makes up the connectivity of the user element. A scalar node is defined using the keyword `*NODE_SCALAR_VALUE`, in which the user also prescribe initial and boundary conditions associated with the extra variables. The connectivity of the user elements must then be specified with the option `*ELEMENT_SOLID_DOF` or `*ELEMENT_SHELL_DOF`, where an extra line is used to connect the scalar nodes to the element. As an example:

```
*NODE_SCALAR_VALUE
$   NID          V1          V2          V3      NDF
    11          1.0          1.0          1.0      1
    12          1.0          1.0          1.0      1
    13          1.0          1.0          1.0      1
    14          1.0          1.0          1.0      1

*ELEMENT_SHELL_DOF
$   EID      PID      N1      N2      N3      N4
    1         1         1       2       3       4
$           NS1      NS2      NS3      NS4
           11       12       13       14
```

defines an element with one extra degree of freedom. The initial value of the corresponding variable is 1.0 and it is unconstrained. Finally, the user sets the parameter `NXDof` on the `*SECTION_...` card to 1, 2 or 3 depending on how many extra degrees of freedom that should be used in the user-defined element. An array `xdof` containing the current values of these extra variables are passed to the user routines for setting up the correct kinematical properties, see comments in the routines for more information. The formula for the displacement index changes to

$$k = (n + n_{xdof})(m - 1) + d$$

where n_{xdof} is the number of extra degrees of freedom. The extra degrees of freedom for each node corresponds to $n + 1 \leq d \leq n + n_{xdof}$. For dynamic simulations, the mass corresponding to these extra nodes are defined using `*ELEMENT_INERTIA` or `*ELEMENT_MASS`.

Sample User Shell Element 101 (Belytschko-Tsay shell)

The geometry of the Belytschko-Tsay element in local coordinates can be written

$$x_i = (x_{iI} + \frac{t}{2} \tilde{\zeta}_3 \delta_{i3}) N_I(\tilde{\zeta}_1, \tilde{\zeta}_2)$$

$$v_i = (v_{iI} + \frac{t}{2} \tilde{\zeta}_3 e_{ij3} \omega_{jI}) N_I(\tilde{\zeta}_1, \tilde{\zeta}_2)$$

Where,

$$x_{iI} = i\text{th component of coordinate of node } I$$

$$v_{iI} = i\text{th component of translational velocity of node } I$$

$$\omega_{jI} = j\text{th component of rotational velocity of node } I$$

$$t = \text{thickness of element}$$

e_{ijk} = permutation tensor
 N_I = shape function localized at node I
 δ_{i3} = Kronecker delta

Taking the derivative of these expressions with respect to the isoparametric coordinate yields

$$\begin{aligned}\frac{\partial x_i}{\partial \bar{\xi}_1} &= (x_{i1} + \frac{t}{2} \bar{\xi}_3 \delta_{i3}) \frac{\partial N_I}{\partial \bar{\xi}_1} \\ \frac{\partial x_i}{\partial \bar{\xi}_2} &= (x_{i1} + \frac{t}{2} \bar{\xi}_3 \delta_{i3}) \frac{\partial N_I}{\partial \bar{\xi}_2} \\ \frac{\partial x_i}{\partial \bar{\xi}_3} &= \frac{t}{2} \delta_{i3}\end{aligned}$$

and

$$\begin{aligned}\frac{\partial v_i}{\partial \bar{\xi}_1} &= (v_{i1} + \frac{t}{2} \bar{\xi}_3 e_{ij3} \omega_{j1}) \frac{\partial N_I}{\partial \bar{\xi}_1} \\ \frac{\partial v_i}{\partial \bar{\xi}_2} &= (v_{i1} + \frac{t}{2} \bar{\xi}_3 e_{ij3} \omega_{j1}) \frac{\partial N_I}{\partial \bar{\xi}_2} \\ \frac{\partial v_i}{\partial \bar{\xi}_3} &= \frac{t}{2} e_{ij3} \omega_{j1} N_I\end{aligned}$$

respectively. Using these expressions the element is implemented as a user-defined shell as follows.

Sample User Solid Element 101 (constant stress solid)

The geometry for the constant stress solid is given as

$$\begin{aligned}
 x_i &= x_{iI}N_I(\xi_1, \xi_2) \\
 v_i &= v_{iI}N_I(\xi_1, \xi_2)
 \end{aligned}$$

where,

$$\begin{aligned}
 x_{iI} &= \textit{ith} \text{ component of coordinate of node } I \\
 v_{iI} &= \textit{ith} \text{ component of translational velocity of node } I \\
 N_I &= \text{shape function localized at node } I
 \end{aligned}$$

The matrices necessary for implementing this element as a user-defined solid are derived from the expressions given by

$$\frac{\partial x_i}{\partial \xi_1} = x_{iI} \frac{\partial N_I}{\partial \xi_1}$$

APPENDIX C

$$\frac{\partial x_i}{\partial \bar{\xi}_2} = x_{il} \frac{\partial N_I}{\partial \bar{\xi}_2}$$

$$\frac{\partial x_i}{\partial \bar{\xi}_3} = x_{il} \frac{\partial N_I}{\partial \bar{\xi}_3}$$

and,

$$\frac{\partial v_i}{\partial \bar{\xi}_1} = v_{il} \frac{\partial N_I}{\partial \bar{\xi}_1}$$

$$\frac{\partial v_i}{\partial \bar{\xi}_2} = v_{il} \frac{\partial N_I}{\partial \bar{\xi}_2}$$

$$\frac{\partial v_i}{\partial \bar{\xi}_3} = v_{il} \frac{\partial N_I}{\partial \bar{\xi}_3}$$

The user element implementation is given by

```

To use the element for a part the section card can be written as

```
*SECTION_SOLID
$   SECID   ELFORM
      1       101
$   NIP     NXDOF   IHGF
      1         0       1
$   XI      ETA     ZETA   WGT
      0.       0.     0.     8.0
```

Examples

We present three test examples.

One example was a simple tension-compression test of a solid cylinder. The geometry is shown in [Figure 47-1](#). The problem is using the sample implementations of user

elements and compared the results and performance with standard LS-DYNA elements. As for the computational efficiency, we note that the performance is worse but this is expected since there is little room for optimization of the code while retaining a user friendly interface. The implicit performance compares well with the other elements in LS-DYNA.

The second example was a combined bending and stretching example with the geometry shown in [Figure 47-2](#). Again we ran the problem with the user element implementations and compared the results and performance with standard LS-DYNA elements. We could see the same tendencies as for the solid elements.

The third and final example is an impact between a solid bar and shell beam. Both parts are modeled with user-defined elements. The results were very similar to the ones obtained by substituting the sections for standard LS-DYNA sections, but the simulation time was about 3-4 times longer.

Tension test (3D solid)

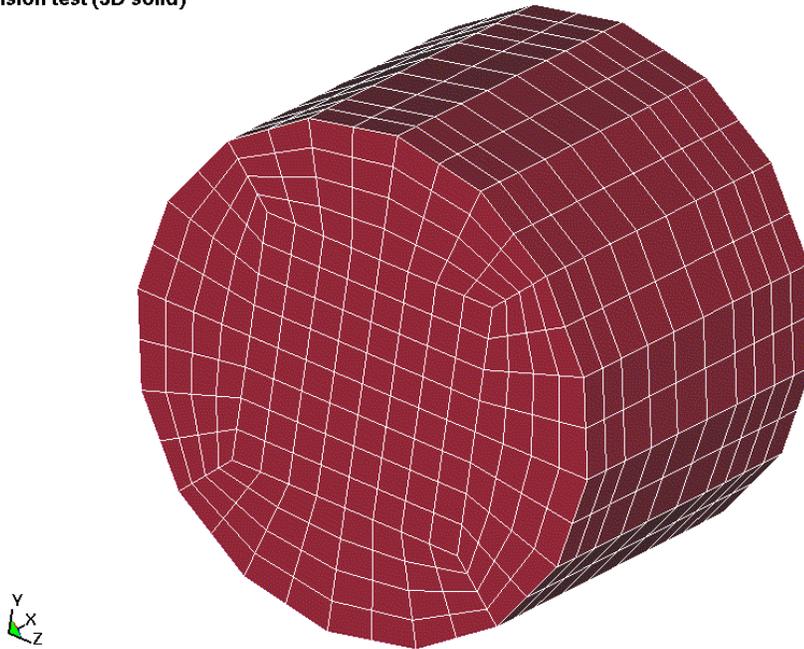

Figure 47-1. Solid mesh for user element test.

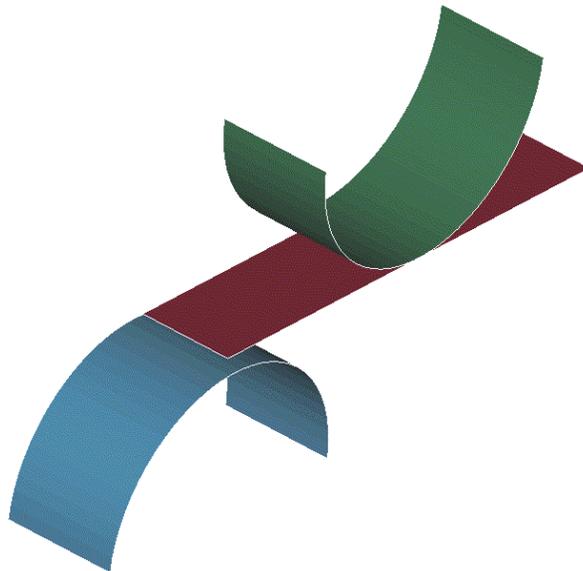

Figure 47-2. Shell mesh for the user element test.

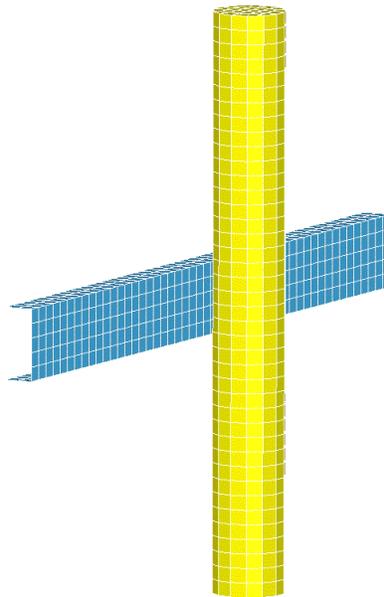

Figure 47-3. Impact between a user-defined shell and user-defined solid part.

APPENDIX D: User Defined Airbag Sensor

The addition of a user sensor subroutine into LS-DYNA is relatively simple. The sensor is mounted on a rigid body which is attached to the structure. The motion of the sensor is provided in the local coordinate system defined for the rigid body in the definition of material model 20—the rigid material. When the user defined criterion is met for the deployment of the airbag, a flag is set and the deployment begins. All load curves relating to the mass flow rate versus time are then shifted by the initiation time. The user subroutine is given below with all the necessary information contained in the comment cards.

```

      subroutine airusr (rbu,rbv,rba,time,dt1,dt2,param,hist,itron,
.   rbug,rbvg,rbag,icnv)
c

c*****
c
c   user subroutine to initiate the inflation of the airbag
c
c   variables
c
c   displacements are defined at time n+1 in local system
c   velocities are defined at time n+1/2 in local system
c   accelerations are defined at time n in local system
c
c   rbu(1-3) total displacements in the local xyz directions
c   rbu(3-6) total rotations about the local xyz axes
c   rbv(1-3) velocities in the local xyz directions
c   rbv(3-6) rotational velocities about the local xyz axes
c   rba(1-3) accelerations in the local xyz directions
c   rba(3-6) rotational accelerations about the local xyz axes
c   time is the current time
c   dt1 is time step size at n-1/2
c   dt2 is time step size at n+1/2
c   param is user defined input parameters
c   hist is user defined history variables
c   itrnon is a flag to turn on the airbag inflation
c   rbug,rbvg,rbag, are similar to rbu,rbv,rba but are defined
c       globally.
c   icnv is the airbag ID
c
c   the user subroutine sets the variable itrnon to:
c
c       itrnon=0 bag is not inflated
c       itrnon=1 bag inflation begins and this subroutine is
c           not called again
c
c   include 'iounits.inc'
c   dimension rbu(6),rbv(6),rba(6),param(25),hist(25),
.   rbug(6),rbvg(6),rbag(6)
c
c   itrnon=0
c   ra=sqrt(rba(1)**2+rba(2)**2+rba(3)**2)
c   if (ra.gt.param(1)) then

```

APPENDIX D

```
        itrnon=1
        write(iotty,100) time
        write(iohsp,100) time
        write(iomsg,100) time
    endif
100 format (' Airbag activated at time ',1pe10.3)
c
    return
end
```

APPENDIX E: User Defined Solution Control

This subroutine may be provided by the user to control the I/O, monitor the energies and other solution norms of interest, and to shut down the problem whenever he pleases. The arguments are defined in the listing provided below. This subroutine is called each time step and does not need any control card to operate.

```

      subroutine uctrl1 (numnp,ndof,time,dt1,dt2,prtc,pltc,frci,prto,
      . plto,frco,vt, vr, at, ar, ut, ur, xmst,xmsr,irbody,rbdyn,usrhv,
      . messag,totalm,cycle,idrint,mtype,mxrb,nrba,rbcor,x,rbv,nrbn,
      . nrb,xrb,yrb,zrb,axrb,ayrb,azrb,dtx,nmmat,rba,fvalnew,fvalold,
      . fvalmid,fvalnxt)
c

c      beginning of time step n+1.  The time at n+
c
c
c      note:  ls-dyna3d uses an internal numbering system to
c             accomodate arbitrary node numbering.  to access
c             information for user node n, address array location m,
c             m = lqf8(n,1).  to obtain user node number, n,
c             corresponding to array address m, set n = lqfinv(m,1)
c
c      arguments:
c      numnp = number of nodal points
c      ndof  = number of degrees of freedom per node
c      time  = current solution time at n+1
c      dt1   = time step size between time n-1 and n
c      dt2   = time step size between time n and n+1
c      prtc  = output interval for taurus time history data
c      pltc  = output interval for taurus state data
c      frci  = output interval for taurus interface force data
c      prto  = output time for time history file
c      plto  = output time for state data
c      frco  = output time for force data
c      vt(3,numnp) = nodal translational velocity vector
c      vr(3,numnp) = nodal rotational velocity vector.  this
c                  array is defined if and only if ndof = 6
c      at(3,numnp) = nodal translational acceleration vector
c      ar(3,numnp) = nodal rotational acceleration vector.  this
c                  array is defined if and only if ndof = 6
c      ut(3,numnp) = nodal translational displacement vector
c      ur(3,numnp) = nodal rotational displacement vector.  this
c                  array is defined if and only if ndof = 6
c      xmst(numnp) = reciprocal of nodal translational masses
c      xmsr(numnp) = reciprocal of nodal rotational masses.  this
c                  array is defined if and only if ndof = 6

```

APPENDIX E

```
c      fvalold      = array for storing load curve values at time n
c      fvalnew      = array for setting load curve values at time n+1
c                  only load curves with 0 input points may be user
c                  defined.  When the load curve is user set, the
c                  value at time n must be stored in array fvalold.
c      fvalmid      = array for predicting load curve values at time n+3/2
c      fvalnxt      = array for predicting load curve values at time n+2
c                  for some applications it is necessary to predict the
c                  load curve values at time n+2, a time that is not
known,
c
c                  this for instance for boundary prescribed motion.  In
c                  this case the load curve values at time n+3/2 need to
c                  be predicted in fvalmid, and fvalold should be set to
c                  fvalnew and fvalnew should be set to fvalnxt.  See
c                  coding below.
c

APPENDIX G: User Defined Interface Friction and Conductivity

An easy-to-use user contact interface is provided in LS-DYNA where the user has the possibility to define the frictional coefficients (static and dynamic) as well as contact heat transfer conductance as functions of contact pressure, relative sliding velocity, separation and temperature. To be able to use this feature, an object version of the LS-DYNA code is required and the user must write his/her own Fortran (or C) code to define the contact parameters of interest.

In the text file `dyn21.f` that comes with the object version of LS-DYNA, the subroutines of interest are

```
subroutine usrfrc(fstt,fdyn,...)
```

for defining the frictional coefficients `fstt` (static) and `fdyn` (dynamic) and

```
subroutine usrhcon(h,...)
```

for defining the heat transfer contact conductance `h`. Due to the significant change in characteristics between the regular node-to-surface contact and segment-to-segment Mortar contact, the subroutine

```
subroutine mortar_usrfrc(...)
```

is intended for usage with Mortar contact. This routine is supposed to return the coefficient of friction for the current contact state, and is in this sense very similar to the other routine. For explanation of all arguments we refer to the source code.

We emphasize at this point that the user friction interface for non-Mortar differs between LS-DYNA (SMP) and MPP-DYNA (MPP), for reasons that have to do with how the contacts are implemented in general. In LS-DYNA (SMP) the user is required not only to define the frictional coefficients but also to assemble and store contact forces and history, whereas in MPP-DYNA (MPP) only the frictional coefficients have to be defined. For Mortar contact, the same routine is called for both SMP and MPP, and only one frictional coefficient needs to be defined.

For the friction interface (SMP and MPP) the user may associate history variables with each contact node (or segment for Mortar contact). Unfortunately, the user friction interface is currently not supported by all available contacts in LS-DYNA and MPP-DYNA, but it should cover the most interesting ones among others, `*CONTACT_(FORMING_)NODES_TO_SURFACE`, `*CONTACT_(FORMING_)SURFACE_TO_SURFACE`, `*CONTACT_(FORMING_)ONE_WAY_SURFACE_TO_SURFACE` and all Mortar contacts. Upon request by customers additional contact types can be supported.

One of the arguments to the user contact routines is the curve array `crv`, also available in the user material interface. Note that when using this array, the curve identity must

APPENDIX G

be converted to an internal number or the subroutine `crvval` may be utilized. For more information, see the appendix A on user materials.

For definition of user contact parameters the user must define the keywords

`*USER_INTERFACE_FRICTION`

or

`*USER_INTERFACE_CONDUCTIVITY`

The card format for these two keywords are identical and can be found in other sections in this manual.

There is an alternate route to defining the conductivity parameters for a user defined thermal contact. On the `*CONTACT..._THERMAL_FRICTION` optional card the parameter `FORMULA` may be set to a negative number. This will automatically create a user defined conductivity interface and invoke reading of `-FORMULA` contact parameters immediately following the card including the `FORMULA` parameter. Note that `FORMULA` is related to `NOC` and `NOCI` in the `*USER_INTERFACE_CONDUCTIVITY` keyword as

$$-FORMULA = NOC = NOCI.$$

Note that the pressure is automatically computed for each user conductivity interface, i.e., the keyword `*LOAD_SURFACE_STRESS` is not necessary.

A sample friction subroutine for the non-Mortar case is provided below for SMP, for Mortar contact we refer to the source code for an example.

```
      subroutine usrfrc(nosl,time,ncycle,dt2,insv,areas,xs,ys,zs,
.   lsv,ix1,ix2,ix3,ix4,aream,xx1,xx2,xx3,stfn,stf,fni,

APPENDIX H: User Defined Thermal Material Model

The addition of a thermal user material routine into LS-DYNA is fairly straightforward. The thermal user material is controlled using the keyword `*MAT_THERMAL_USER_DEFINED`, which is described at the appropriate place in the manual.

The thermal user material can be used alone or in conjunction with any given mechanical material model in a coupled thermal-mechanical solution. A heat-source can be included and the specific heat updated so that it possible to model e.g. phase transformations including melt energy.

If for the same part (shell or solid elements) both a thermal and mechanical user material model is defined then the two user material models have (optionally) read access to each other's history variables. If the integration points of the thermal and mechanical elements not are coincident then interpolation or extrapolation is used when reading history variables. Linear interpolation or extrapolation using history data from the two closest integration points is used in all cases except when reading history variables from the thick thermal shell (`THSHEL = 1` on `*CONTROL_SHELL`). For the latter thermal shell, the shape functions of the element are used for the interpolation or extrapolation.

The thermal user materials are thermal material types 11-15. These thermal user material subroutines are defined in file `dyn21.f` as subroutines `thumat11`, ... , `thumat15`. The latter subroutines are called from the subroutine `thusrmat`. The source code of subroutine `thusrmat` is also in file `dyn21.f`. Additional useful information is available in the comments of subroutines `thusrmat`, `thumat12`, and `umat46` that all reside in the source file `dyn21.f`

Thermal history variables

Thermal history variables can be used by setting `NVH` greater than 0. Thermal history variables are output to the `tprint` file, see `*DATABASE_TPRINT`.

Interchange of history variables with mechanical user material

In a coupled thermo-mechanical solution there is for each mechanical shell, thick shell, or solid element a corresponding thermal element. A pair consisting of a mechanical and a corresponding thermal element both have integration points and possibly history variables. The mechanical and thermal elements do not necessarily have the same number of integration points.

APPENDIX H

By setting IHVE to 1, a thermal user material model can read, but not write, the history variables from a mechanical user material model and vice versa.

If the locations of the points where the history variables are located differ between the mechanical and thermal element differ interpolation or extrapolation is used to calculate the history value. More information is available in the comments to the subroutines thusrmat and thumat11.

Limitations:

Currently there are a few limitations of the thermal user material implementation. LS-DYNA will in most cases give an appropriate warning or error message when such a limit is violated. The limitations include:

1. Option IHVE.EQ.1 is only supported for a limited range of mechanical elements:
 - a) Solid elements: ELFORM = 1, 2, 10, 13.
 - b) Shell elements: ELFORM = 2, 3, 4, 16. Note that user-defined integration rules are not supported.
2. Thermal history variables limitations:
 - a) Thermal history variables are not output to d3plot.
3. The thermal solver includes not only the plastically dissipated energy as a heat source but also wrongly the elastic energy. The latter however is in most cases not of practical importance.

Example source code:

Example source code for thermal user material models is available in thumat11 and thumat12 as well as in umat46. Note that there is space for up to 64 material parameters in r_matp (material parameter array) but only 32 can be read in from the *MAT_THERMAL_USER_DEFINED card. The material parameters in r_matp(i), i = 41-64, which are initially set to 0.0, may be used by the user to store additional data.

Subroutine crvval evaluates load curves. Note that when using crvval the load curves are first re-interpolated to 100 equidistant points. See Appendix A for more information on subroutine crvval.

Following is a short thermal user material model. The card format is in this case, if enabling orthotropic conduction, and with sample input in SI-units:

APPENDIX I: Occupant Simulation Including the Coupling to the CAL3D and MADYMO programs

INTRODUCTION

LS-DYNA is coupled to occupant simulation codes to generate solutions in automotive crashworthiness that include occupants interacting with the automotive structure. In such applications LS-DYNA provides the simulation of the structural and deformable aspects of the model and the OSP (Occupant Simulation Program) simulates the motion of the occupant. There is some overlap between the two programs which provides flexibility in the modeling approach. For example, both the OSP and LS-DYNA have the capability of modeling seat belts and other deformable restraints. The advantage of using the OSP is related to the considerable databases and expertise that have been developed in the past for simulating dummy behavior using these programs.

The development of the interface provided LSTC a number of possible approaches. The approach selected is consistent with the LSTC philosophy of providing the most flexible and useful interface possible. This is important because the field of non-linear mechanics is evolving rapidly and techniques which are used today are frequently rendered obsolete by improved methodologies and lower cost computing which allows more rigorous techniques to be used. This does make the learning somewhat more difficult as there is not any single procedure for performing a coupling.

One characteristic of LS-DYNA is the large number of capabilities, particularly those associated with rigid bodies. This creates both an opportunity and a difficulty: LS-DYNA3D has many ways approximating different aspects of problems, but they are frequently not obvious to users without considerable experience. Therefore, in this Appendix we emphasize modeling methods rather than simply listing capabilities.

THE LS-DYNA/OCCUPANT SIMULATION PROGRAM LINK

Coupling between the OSP and LS-DYNA is performed by combining the programs into a single executable. In the case of CAL3D, LS-DYNA calls CAL3D as a subroutine, but in the case of MADYMO, LS-DYNA is called as a subroutine. The two programs are then integrated in parallel with the results being passed between the two until a user defined termination time is reached.

The OSP and LS-DYNA have different approaches to the time integration schemes. The OSP time integrators are based on accurate implicit integrators which are valid for large time steps which are on the order of a millisecond for the particular applications of

APPENDIX I

interest here. An iterative solution is used to insure that the problem remains in equilibrium. The implicit integrators are extremely good for smoothly varying loads, however, sharp nonlinear pulses can introduce considerable error. An automatic time step size control which decreases the time step size quickly restores the accuracy for such events. The LS-DYNA time integrator is based on an explicit central difference scheme. Stability requires that the time step size be less than the highest frequency in the system. For a coarse airbag mesh, this number is on the order of 100 microseconds while an actual car crash simulation is on the order of 1 microsecond. The smallest LS-DYNA models have at least 1,000 elements. Experience indicates that the cost of a single LS-DYNA time step for a small model is at least as great as the cost of a time step in the OSP. Therefore, in the coupling, the LS-DYNA time step is used to control the entire simulation including the OSP part. This approach has negligible cost penalties and avoids questions of stability and accuracy that would result by using a subcycling scheme between the two programs.

LS-DYNA has a highly developed rigid body capability which is used in different parts of automobile crash simulation. In particular, components such as the engine are routinely modeled with rigid bodies. These rigid bodies have been modified so that they form the basis of the coupling procedure in LS-DYNA to the OSP.

Please contact the LSTC technical support team (support@lstc.com) for instructions to download and run LS-DYNA executables coupled with Madymo.

AIRBAG MODELING

Modeling of airbags is accomplished by use of shell or membrane elements in conjunction with a control volume (see **AIRBAG_OPTION*) and possibly a single surface contact algorithm to eliminate interpenetrations during the inflation phase (see **CONTACT_OPTION*). The contact types showing an “a” in front are most suited for airbag analysis. Current recommended material types for the airbags are:

1. **MAT_ELASTIC* (Type 1, Elastic)
2. **MAT_COMPOSITE_DAMAGE* (Type 22, layered orthotropic elastic for composites)
3. **MAT_FABRIC* (Type 34, fabric model for folded airbags)

Model 34 is a “fabric” model which can be used for flat bags. As a user option this model may or may not support compression.

The elements which can be used are as follows:

1. Belytschko-Tsay quadrilateral with 1 point quadrature. This element behaves rather well for folded and unfolded cases with only a small tendency to hour-

- glass. The element tends to be a little stiff. Stiffness form hourglass control is recommended.
2. Belytschko-Tsay membrane. This model is softer than the normal Belytschko-Tsay element and can hourglass quite badly. Stiffness form hourglass is recommended. As a better option, the fully integrated Belytschko-Tsay membrane element can be chosen.
 3. C0 Triangular element. The C0 triangle is very good for flat bag inflation and has no tendency to hourglass.
 4. The best choice is a specially developed airbag membrane element with quadrilateral shape. This is an automatic choice when the fabric material is used.

As an airbag inflates, a considerable amount of energy is transferred to the surrounding air. This energy transfer decreases the kinetic energy of the bag as it inflates. In the control volume logic, this is simulated either by using either a mass weighted damping option or a back pressure on the bag based on a stagnation pressure. In both cases, the energy that is absorbed is a function of the fabric velocity relative to a rigid body velocity for the bag. For the mass weighted case, the damping force on a node is proportional to the mass times the damping factor times the velocity vector. This is quite effective in maintaining a stable system, but has little physical justification. The latter approach using the stagnation pressure method estimates the pressure needed to accelerate the surrounding air to the speed of the fabric. The formula for this is:

$$P = \text{Area} \times \alpha \times [(\vec{V}_i - \vec{V}_{cg}) \cdot \hat{n}]^2$$

This formula accomplishes a similar function and has a physical justification. Values of the damping factor, α , are limited to the range of 0 to 1, but a value of 0.1 or less is more likely to be a good value.

COMMON ERRORS

1. Improper airbag inflation or no inflation.

The most common problem is inconsistency in the units used for the input constants. An inflation load curve must also be specified. The normals for the airbag segments must all be consistent and facing outwards. If a negative volume results, this can sometimes be quickly cured by using the “flip” flag on the control volume definition to force inward facing normals to face outwards.

2. Excessive airbag distortions.

Check the material constants. Triangular elements should have less distortion problems than quadrilaterals. Overlapped elements at time zero can cause

APPENDIX I

locking to occur in the contact leading to excessive distortions. The considerable energy input to the bag will create numerical noise and some damping is recommended to avoid problems.

3. The dummy passes through the airbag.

A most likely problem is that the contacts are improperly defined. Another possibility is that the models were developed in an incompatible unit system. The extra check for penetration flag if set to 1 on the contact control cards variable PENCHK in the *CONTACT_... definitions may sometimes cause nodes to be prematurely released due to the softness of the penalties. In this case the flag should be turned off.

4. The OSP fails to converge.

This may occur when excessively large forces are passed to the OSP. First, check that unit systems are consistent and then look for improperly defined contacts in the LS-DYNA input.

5. Time step approaches zero.

This is almost always in the airbag. If elastic or orthotropic (*MAT_ELASTIC or *MAT_COMPOSITE material 1 or 22) is being used, then switch to fabric material *MAT_FABRIC which is less time step size sensitive and use the fully integrated membrane element. Increasing the damping in the control volume usually helps considerably. Also, check for "cuts" in the airbag where nodes are not merged. These can allow elements to deform freely and cut the time step to zero.

APPENDIX J: Interactive Graphics Commands

Only the first four or less characters of command are significant. These commands are available in the interactive phase of LS-DYNA. The interactive graphics are available by using the "SW5." command after invoking the Ctrl-C interrupt. The MENU command brings up a push button menu. Only available in Unix and Linux.

| | |
|---------|--|
| ANIMATE | Animate saved sequence, stop with switch 1. |
| BACK | Return to previous display size after zoom, then list display attributes. |
| BGC | Change display background color RGB proportions BGC <red> <green> <blue>. |
| BIP | Select beam integration point for contour; BIP <#>. |
| CENTER | Center model, center on node, or center with mouse, i.e., center cent <value> or cent gin. |
| CL | Classification labels on display; class commercial_in_confidence. |
| CMA | Color materials on limited color displays. |
| COLOR | Set or unset shaded coloring of materials. |
| CONTOUR | View with colored contour lines; contour < component #> < list mat #>; see TAURUS manual. |
| COOR | Get node information with mouse. |
| COP | Hardcopy of display on the PC copy < laserj paintj tekcol coljet or epson>. |
| CR | Restores cutting plane to default position. |
| CUT | Cut away model outside of zoom window; use mouse to set zoom window size. |
| CX | Rotate slice plane at zmin about x axis. |
| CY | Rotate slice plane at zmin about y axis. |
| CZ | Rotate slice plane at zmin about z axis. |

APPENDIX J

| | |
|------------|---|
| DIF | Change diffused light level for material; DIF < mat #, -1 for all > <value>. |
| DISTANCE | Set distance of model from viewer; DIST < value in normalized model dimensions>. |
| DMATERIALS | Delete display of material in subsequent views; DMAT < ALL or list of numbers>. |
| DRAW | Display outside edges of model. |
| DSCALE | Scale current displacement from initial shape. |
| DYN | After using TAURUS command will reset display to read current DYNA3D state data. |
| ELPLT | Set or unset element numbering in subsequent views. |
| END | Delete display and return to execution. |
| ESCAPE | Escapes from menu pad mode. |
| EXECUTE | Return to execution and keep display active. |
| FCL | Fix or unfix current contour levels. |
| FOV | Set display field of view angle; FOV < value in degrees>. |
| FRINGE | View with colored contour fringes; fringe < component #> < list mat #>; see TAURUS manual. |
| GETFRAME | Display a saved frame; GETF < frame #>. |
| HARDWARE | Hardware mode; workstation hardware calls are used to draw, move and color model; repeat command to reset to normal mode. |
| HELP | |
| HZB | Switch on or off hardware zbuffer for a subsequent view, draw or contour command; rotations and translations will be in hardware. |
| LIMIT | Set range of node numbers subsequent views; limit < first node #> < last node #>. |
| MAT | Re-enable display of deleted materials mat < all or list of numbers>. |

| | |
|------------------|--|
| MENU | Button menu pad mode. |
| MOTION | Motion of model through mouse movement or use of a dial box. The left button down enables translation in the plane, middle button rotation about axes in the plane; and with right button down in the out of plane axis; left and middle button down quit this mode. |
| MOV | Drag picked part to new position set with mouse. |
| NDPLT | Set or unset node numbering in subsequent views. |
| NOFRAME | Set and unset drawing of a frame around the picture. |
| PAUSE | Animation display pause in seconds |
| PHS2 or THISTORY | Time history plotting phase. Similar to LS-TAURUS. |
| PICK | Get element information with mouse. |
| POST | Enable or disable postscript mode on the PC and eps file is written as picture is drawn; remove eofs and init-graphics for eps use. |
| QUIT | Same as execute. |
| RANGE | Set fix range for contour levels; range <minvalue> <maxvalue>. |
| RAX | Reflect model about xy plane; restore command will switch-off reflections. |
| RAY | Reflect model about yz plane; restore command will switch-off reflections. |
| RAZ | Reflect model about zx plane, restore command will switch-off reflections. |
| RESTORE | Restores model to original position, also switches off element and node numbers, slice capper, reflections and cut model. |
| RETURN | Exit. |
| RGB | Change color red green blue element < mat #> <red> <green> <blue>. |
| RX | Rotate model about x axis. |

APPENDIX J

| | |
|---------------|---|
| RY | Rotate model about y axis. |
| RZ | Rotate model about z axis. |
| SAVE | Set or unset saving of display for animation. |
| SEQUENCE | Periodic plot during execution; SEQ <# of cycles > <commands> EXE. |
| SHR | Shrink element facets towards centroids in subsequent views, shrink <value>. |
| SIP | Select shell integration point for contour; SIP <#>. |
| SLICE | Slice model a z-minimum plane; slice < value in normalized model dimension > this feature is removed after using restore. Slice enables internal details for brick elements to be used to generate new polygons on the slice plane. |
| SNORMAL | Set or unset display of shell direction normals to indicate topology order. |
| SPOT | Draw node numbers on model spot < first #> < last # for range>. |
| TAURUS | LS-DYNA database, TAU < state #>, or state < state #>, reads LS-TAURUS file to extract previous state data. |
| TRIAD | Set or unset display of axis triad. |
| TSHELL | Set or unset shell element thickness simulation in subsequent views. |
| TV | Change display type. |
| TX | Translates model along x axis. |
| TY | Translates model along y axis. |
| TZ | Translates model along z axis. |
| V | Display model using painters algorithm. |
| VECTOR v or d | View with vector arrows of velocity or displacement; <v> or <d>. |
| ZB | Switch on or off zbuffer algorithm for subsequent view; or draw commands. |
| ZIN | Zoom in using mouse to set display size and position. |

| | |
|------|---|
| ZMA | Set position of zmax plane; ZMAX < value in normalized model dimensions>. |
| ZMI | Set position of zmin plane; ZMIN < value in normalized model dimensions>. |
| ZOUT | Zoom out using mouse to set displays size expansion and position. |

APPENDIX K: Interactive Material Model Driver

INTRODUCTION

The interactive material model driver in LS-DYNA allows calculation of the material constitutive response to a specified strain path. Since the constitutive model subroutines in LS-DYNA are directly called by this driver, the behavior of the constitutive model is precisely that which can be expected in actual applications. In the current implementation the constitutive subroutines for both shell elements and solid elements can be examined.

INPUT DEFINITION

The material model driver is invoked when no *NODE or *ELEMENT commands are present in a standard LS-DYNA input file. The number of material model definitions should be set to one, the number of load curves should be nine, and the termination time to the desired length of the driver run. The complete state dump interval as given in *DATABASE_BINARY_D3PLOT serves as the time step to be used in the material model driver run. Plotting information is saved in core for the interactive plotting phase.

The input deck typically consists only of *KEYWORD, *DATABASE_BINARY_D3PLOT, *CONTROL_TERMINATION, one each of *PART/*MAT/*SECTION, and nine load curves (*DEFINE_CURVE) describing the strain path. These nine curves define the time history of the displacement gradient components shown in [Table 55-1](#).

The velocity gradient matrix, L_{ij} , is approximated by taking the time derivative of the components in [Table 55-1](#). If these components are considered to form a tensor S_{ij} , then

$$L_{ij}(t) = \frac{S_{ij}(t) - S_{ij}(t_{k-1})}{(t - t_k)}$$

and the strain rate tensor is defined as

$$d_{ij} = \frac{L_{ij} + L_{ij}^t}{2}$$

and the spin tensor as

$$\omega_{ij} = \frac{L_{ij} - L_{ij}^t}{2}$$

APPENDIX K

| Load Curve Number | Component Definition |
|-------------------|---------------------------------|
| 1 | $\frac{\partial u}{\partial x}$ |
| 2 | $\frac{\partial v}{\partial y}$ |
| 3 | $\frac{\partial w}{\partial z}$ |
| 4 | $\frac{\partial u}{\partial y}$ |
| 5 | $\frac{\partial v}{\partial x}$ |
| 6 | $\frac{\partial u}{\partial z}$ |
| 7 | $\frac{\partial w}{\partial x}$ |
| 8 | $\frac{\partial v}{\partial z}$ |
| 9 | $\frac{\partial w}{\partial y}$ |

Table 55-1. Load Curve Definitions versus Time

INTERACTIVE DRIVER COMMANDS

After reading the input file and completing the calculations, LS-DYNA gives a command prompt to the terminal. A summary of the available interactive commands is given below. An on-line help package is available by typing HELP. Only available in Unix and Linux.

| | |
|----------------|--|
| ACCL | Scale all abscissa data by f. Default is f = 1. |
| ASET amin omax | Set min and max values on abscissa to amin and amax, respectively. If amin = amax = 0, scaling is automatic. |
| CHGL n | Change label for component n. LS-DYNA prompts for new label. |

| | |
|--------------------|---|
| CONTINUE | Re-analyze material model. |
| CROSS c_1 c_2 | Plot component c_1 versus c_2 . |
| ECOMP | Display component numbers on the graphics display: EQ.1: x-stress, EQ.2: y-stress, EQ.3: z-stress, EQ.4: xy-stress, EQ.5: yz-stress, EQ.6: zx-stress, EQ.7: effective plastic strain, EQ.8: pressure, EQ.9: von Mises (effective) stress, EQ.10: 1st principal deviatoric stress, EQ.11: 2nd principal deviatoric stress, EQ.12: 3rd principal deviatoric stress, EQ.13: maximum shear stress, EQ.14: 1st principal stress, EQ.15: 2nd principal stress, EQ.16: 3rd principal stress, EQ.17: $\ln(v/v_0)$, EQ.18: relative volume, EQ.19: $v_0/v - 1.0$, EQ.20: 1st history variable, EQ.21: 2nd history variable. Adding 100 or 400 to component numbers 1-16 yields strains and strain rates, respectively. |
| FILE name | Change pampers filename to name for printing. |
| GRID | Graphics displays will be overlaid by a grid of orthogonal lines. |
| NOGRID | Graphics displays will not be overlaid by a grid of orthogonal lines. |
| OSCL | Scale all ordinate data by f . Default is $f = 1$. |
| OSET $omin$ $omax$ | Set min and max values on ordinate to $omin$ and $omax$, respectively. If $omin = omax = 0$, scaling is automatic. |

APPENDIX K

| | |
|--|--|
| PRINT | Print plotted time history data into file "pampers." Only data plotted after this command is printed. File name can be changed with the "file" command. |
| QUIT, END, T | Exit the material model driver program. |
| RDLC m n r ₁ z ₁ ... r _n z _n | Redefine load curve m using n coordinate pairs (r ₁ ,z ₁) (r ₂ ,z ₂),...(r _n ,z _n). |
| TIME c | Plot component c versus time. |
| TV n | Use terminal output device type n. LS-DYNA provides a list of available devices. |

Presently, the material model drive is implemented for solid and shell element material models. The driver does not yet support material models for beam elements.

Use the keyword *CONTROL_MPP_MATERIAL_MODEL_DRIVER and run the input deck only on one processor if a distributed memory executable (MPP) is used.

Beginning with Release R11, it is possible to use the material model driver in batch mode. That means if a file called "mmd.bat" exists in the working directory, then the commands contained therein get executed sequentially without opening an interactive command prompt. Supported commands are print, cross, time, and quit. Example for contents of "mmd.bat" to get effective stress versus plastic strain in a file called "sigeps" and effective stress versus time in "sigtim" is given here (read format '(a8,2x,2e10.0)'):

```
print
sigeps
cross          9          7
print
sigtim
time          9
quit
```

APPENDIX L: VDA Database

VDA surfaces describe the surface of geometric entities and are useful for the simulation of sheet forming problems. The German automobile and automotive supplier industry (VDA) has defined the VDA guidelines [VDA 1987] for a proper surface definition used for the exchange of surface data information. In LS-DYNA, this format can be read and used directly. Some files have to be provided for proper linkage to the motion of the correlation parts/materials in LS-DYNA.

Linking is performed via names. To these names surfaces are attached, which in turn can be linked together from many files externally to LS-DYNA. Thus, arbitrary surfaces can be provided by a preprocessor and then can be written to various files. The so-called VDA file given on the LS-DYNA execution line via `V = vda` contains references to all other files. It also contains several other parameters affecting the treatment in the contact subroutines; see below.

The procedure is as follows. If VDA surfaces are to be used, the file specified by `vda` must have the following form. The file is free formatted with blanks as delimiters. Note that the characters `}` and `{` must be separated from the other input by spaces or new lines. The `vda` file may contain any number of input file specifications of the form:

```
file afile bfile {
    alias definitions
}
alias definitions
followed by optional runtime parameters and a final end statement.
```

The file, `afile`, is optional, and if given must be the name of an ASCII input file formatted in accordance with the VDA Surface Interface Definitions as defined by the German automobile and automotive supply industry. `bfile` is required, and is the name of a binary VDA file. In a first run `afile` is given and `bfile` is created. In any further run, if the definitions have not changed, `afile` can be dropped and only `bfile` is needed. The purpose of `bfile` is that it allows for much faster initialization if the same VDA surfaces are to be used in a future LS-DYNA run.

If `afile` is given, `bfile` will always be created or overwritten. The alias definitions are used for linking to LS-DYNA and between the various surface definitions in the files defined by `afile` and `bfile`.

The alias definitions are of the form

```
alias name { e11 e12 ... e1n }
```

where `name` is any string of up to 12 characters, and `e11,...,e1n` are the names of VDA elements as specified in `afile`. The list of elements can be empty, in which case all the SURF and FACE VDA elements in `afile` will be used. Care should be taken to ensure that the alias `name` is unique, not only among the other aliases, but among the VDA

APPENDIX L

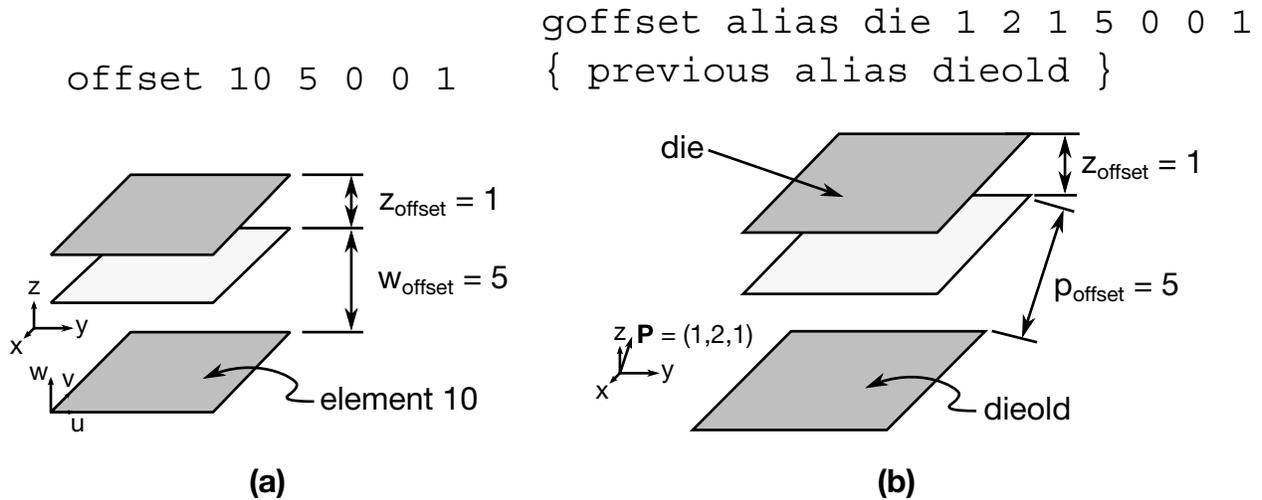

Figure 56-1. (a) a schematic illustration of offset version 1, and (b) is a schematic illustration of offset version 2.

element names in **afile**. This collection of VDA elements can later be indicated by the alias **name**. In particular, **name** may appear in later alias definitions.

Often it is required that a punch or die be created by a simple offset. This can be achieved in the **vda** files in two ways, either on VDA elements directly, or on parts defined by aliases. This feature offers great capability in generating and using surface data information.

Offset Version 1

As an option, the keyword **offset** may appear in the alias list which allows a new surface to be created as a normal offset (plus translation) of a VDA element in the file. The keyword **offset** may be applied to VDA elements only, not aliases. The usage of **offset** follows the form

```
offset elem normal x y z
```

where **normal** is the amount to offset the surface along the normal direction, and **x,y,z** are the translations to be applied. The default normal direction is given by the cross product of the local **u** and **v** directions on the VDA surface, taken in that order. **normal** can be negative.

Offset Version 2

Frequently, it is convenient to create a new alias **name** by offsetting and translating an existing **name**. The keyword **goffset** provides this function:

```
goffset alias name xc yc zc normal x y z { previous alias name }
```

where **normal**, **x**, **y**, and **z** are defined as in the offset keyword. A reference point x_c , y_c , and z_c defines a point in space which determines the normal direction to the VDA surface, which is a vector from the origin to $P(x_c, y_c, z_c)$. See example below.

Finally, several parameters affecting the VDA surface iteration routines can be reset in the file **vda**. These parameters, and their default values in square brackets [], are:

- gap** [5.0] The maximum allowable surface gap to be filled in during the iterations. Points following the surface will effectively extend the edges of surfaces if necessary to keep them from falling through cracks in the surface smaller than this. This number should be set as small as possible while still allowing correct results. In particular, if your VDA surfaces are well formed (having no gaps), this parameter can be set to 0.0. The default value is 5.0.
- track** [2.0] A point must be within this distance of contact to be continually tracked. When a point not being tracked comes close to a surface, a global search is performed to find the near surface point. While a point is being tracked, iterations are performed every cycle. These iterations are much faster, but if the point is far away it is faster to occasionally do the global search. The default value is 2.0.
- track2** [5.0] Every VDA surface is surrounded by a bounding box. When a global search needs to be performed but the distance from a point to this box is $>$ **track2**, the actual global search is not performed. This will require another global search to be performed sooner than if the actual distance to the surface were known, but also allows many global searches to be skipped. The default value is 5.0.
- ntrack** [4] The number of VDA surfaces for which each point maintains actual distance information. A global lower bound on distance is maintained for all remaining surfaces. Whenever the point moves far enough to violate this global lower bound, all VDA surfaces must have the global search performed for them. Hence, this parameter should be set to the maximum number of surfaces that any point can be expected to be near at one time (the largest number of surfaces that come together at one point). Setting **ntrack** higher will require more memory but result in faster execution. If **ntrack** is too low, performance may be unacceptably slow. The default value is 4.0.

APPENDIX L

toroid [.01] Any surface with opposing edges which are within distance [t] of each other is assumed to be cylindrical. Contacts occurring on one edge can pass to the adjacent edge. The default value is 0.01.

converge [.01] When surface iterations are performed to locate the near point, iteration is continued until convergence is detected to within this distance (all VDA coordinates are in mm). The default value is 0.01.

iterate [8] Maximum number of surface iterations allowed. Since points being tracked are checked every cycle, if convergence fails it will be tried again next cycle, so setting this parameter high does not necessarily help much. On the other hand, a point converging to a crease in the VDA surface (a crease between patches with discontinuous derivative, for example) may bounce back and forth between patches up to this many times, without actually moving. Hence, this value should not be too large. The default value is 8.

el_size [t mx mn]

Controls the generation of elements where:

t = surface tolerance for mesh generation,
mx = maximum element size to generate,
mn = minimum element size to generate.

The default values are [0.25 100. 1.0]

aspect [s1 s2] Controls the generation of elements where:

s1 = maximum difference in aspect ratio between elements
generated in neighboring VDA patches,
s2 = maximum aspect ratio for any generated element.

The default values are [1.5 4.0]

cp_space [10] Determines the spacing around the boundaries of parts at which the size of elements is controlled. In the interior of the part, the element size is a weighted function of these control points as well as additional control points in the interior of the region. If there are too few control points around the boundary, elements generated along or near straight boundaries, but between control points, may be too small. The default value is 10.

meshonly The existence of this keyword causes LS-DYNA to generate a file containing the mesh for the VDA surfaces and then terminate.

onepatch The existence of this keyword causes LS-DYNA to generate a single element on each VDA patch.

somepatch [n] Like onepatch, but generates an element for 1 out of every [n] patches.

Example for file V = **vda**. It contains the following data:

```
file vda1 vda1.bin {
    alias die {
        sur0001
        sur0003
        offset fce0006 1.5 0 0 120
    }
    alias holder1 { sur008 }
}
file vda2 vda2.bin {
    alias holder2 { sur003 }
}
alias holder { holder1 holder2 }
ntrack 6
gap 0.5
end
```

Explanation:

| | |
|-----------------------|---|
| vda1 | This file contains the surfaces/face elements sur0001,sur0003, fce0006, and sur0008. |
| alias die face | Combines the surface/face elements sur0001, sur0003, and the offsetted fce0006 to a global surface. |
| alias holder1 | Defines the surface/face element sur0008 as holder1. |
| vda2 | This file contains the surface/face element sur0003. |
| alias holder2 | Defines the surface/face element sur0003 as holder2. |
| alias holder | Combines the surfaces holder1 and holder2 into a combined surface holder. |
| ntrack 6 | For each point the actual distances to 6 VDA surfaces are maintained. |
| gap 0.5 | Surface gaps of 0.5mm or less are filled. |
| end | Closes reading of this file. |

APPENDIX M: Commands for Two-Dimensional Rezoning

The rezoner in LS-DYNA contains many commands that can be broken down into the following categories:

- general,
- termination of interactive rezoning,
- redefinition of output intervals for data,
- graphics window controls,
- graphics window controls for x versus y plots,
- mesh display options,
- mesh modifications,
- boundary modifications,
- MAZE line definitions,
- calculation graphics display control parameters,
- calculation graphics display,
- cursor commands.

The use of the rezoner is quite simple. Commands for rezoning material number *n* can be invoked after the material is specified by the “M *n*” command. To view material *n*, the command “V” is available. The interior mesh can be smoothed with the “S” command and the boundary nodes can be adjusted after the “B” command is used to display the part side and boundary node numbers. Commands that are available for adjusting boundary nodes following the “B” command include:

ER, EZ, ES, VS, BD, ERS, EZS, ESS, VSS, BDS, SLN, SLNS

Rezoning is performed material by material. An example is shown.

Do not include the graphics display type number (see the “TV” command below) when setting up a command file for periodic noninteractive rezoning. No plotting is done when the rezoner is used in this mode.

REZONING COMMANDS BY FUNCTION:

Interactive Real Time Graphics

SEQ *n* commands EXE Every *n* time steps execute the graphics commands which follow. For example the line seq 100 g exe would

APPENDIX M

cause the grid to be updated on the graphics display device every 100 cycles. The real time graphics can be terminated by using ctrl-c and typing "sw7."

General

| | |
|------------------|--|
| C | Comment - proceed to next line. |
| FRAME | Frame plots with a reference grid (default). |
| HELP | Enter HELP package and display all available commands. Description of each command is available in the HELP package. |
| HELP/commandname | Do not enter HELP package but print out the description on the terminal of the command following the slash. |
| LOGO | Put LLNL logo on all plots (default). Retyping this command removes the logo. |
| NOFRAME | Do not plot a reference grid. |
| PHP ans | Print help package - If answer equals 'y' the package is printed in the high speed printer file. |
| RESO $n_x n_y$ | Set the x and y resolutions of plots to n_x and n_y , respectively. We default both n_x and n_y to 1024. |
| TV n | Use graphics output device type n. The types are installation dependent and a list will be provided after this command is invoked. |
| TR t | At time t, LS-DYNA will stop and enter interactive rezoning phase. |

Termination of Interactive Rezoning

| | |
|----------|--|
| F | Terminate interactive phase, remap, continue in execution phase. |
| FR | Terminate interactive phase, remap, write restart dump, and call exit. |
| T or END | Terminate. |

Redefinition of Output Intervals for Data

| | |
|--------|--|
| PLTI t | Reset the node and element data dump interval t. |
| PRTI t | Reset the node and element printout interval t. |
| TERM t | Reset the termination to t. |

Graphics Window Controls

| | |
|--------------|---|
| ESET n | Center picture at element n with a r by z window. This window is set until it is released by the unfix command or reset with another window. |
| FF | Encircle picture with reference grid with tickmarks. Default grid is plotted along bottom and left side of picture. |
| FIX | Set the display to its current window. This window is set until it is reset by the "GSET", "FSET", or "SETF" commands or released by the "UNFIX" command. |
| FSET n r z | Center display at node n with a rectangular $\Delta r \times \Delta z$ window. This window is set until it is reset with or the "UNFIX" command is typed. |
| GSET r z l | Center display picture at point (r,z) with square window of width l. This window is set until it is reset or the "UNFIX" command is typed. |
| GRID | Overlay graphics displays with a grid of orthogonal lines. |
| NOGRID | Do not overlay graphics displays with a grid of orthogonal lines (default). |
| SETF r z r z | Center display at point (r,z) with a rectangular $\Delta r \times \Delta z$ window. This window is set until it is reset or the "UNFIX" command is typed. |
| UNFIX | Release current display window set by the "FIX", "GSET", "FSET" or "SETF" commands. |
| UZ a b l | Zoom in at point (a,b) with window l where a, b, and l are numbers between 0 and 1. The picture is assumed to lie in a unit square. |

APPENDIX M

| | |
|-------------------|--|
| UZG | Cover currently displayed picture with a 10 by 10 square grid to aid in zooming with the unity zoom, "UZ", command. |
| UZOU a b l | Zoom out at point (a,b) with window l where a, b, and l are numbers between 0 and 1. The current window is scaled by the factor $1/\Delta$. The picture is assumed to lie in a unit square. |
| Z r z Δ | Zoom in at point (r,z) with window Δ . |
| ZOUT r z Δ | Zoom out at point (r,z) with window Δ . The window is enlarged by the ratio of the current window and Δ . The cursor may be used to zoom out via the cursor command DZOU and entering two points with the cursor to define the window. The ratio of the current window with the specified window determines the picture size reduction. An alternative cursor command, DZZO, may be used and only needs one point to be entered at the location where the reduction (2 \times) is expected. |

Graphics Window Controls for x versus y plots

The following commands apply to line plots, interface plots, etc.

| | |
|----------------|--|
| ASCL f_a | Scale all abscissa data by f_a . The default is $f_a = 1$. |
| ASET amin amax | Set minimum and maximum values on abscissa to amin and amax, respectively. If amin = amax = 0.0 (default) LS-DYNA determines the minimum and maximum values. |
| OSCL f_o | Scale all ordinate data by f_o . The default is $f_o = 1$. |
| OSET omin omx | Set minimum and maximum values on ordinate to omin and omx, respectively. If omin = omx = 0.0 (default) LS-DYNA determines the minimum and maximum values. |
| SMOOTH n | Smooth a data curve by replacing each data point by the average of the 2n adjacent points. The default is n = 0. |

Mesh Display Options

| | |
|-------|---|
| ELPLT | Plot element numbers on mesh of material n. |
|-------|---|

| | |
|----------|--|
| FSOFF | Turn off the “FSON” command. |
| FSON | Plot only free surfaces and slideline interfaces with “O” command. (Must be used before “O” command.) |
| G | View mesh. |
| GO | View mesh right of centerline and outline left of centerline. |
| GS | View mesh and solid fill elements to identify materials by color. |
| M n | Material n is to be rezoned. |
| MNOFF | Do not plot material numbers with the “O”, “G”, and “GO” commands (default). |
| MNON | Plot material numbers with “O”, “G”, and “GO” commands. |
| NDPLT | Plot node numbers on mesh of material n. |
| O | Plot outlines of all material. |
| RPHA | Reflect mesh, contour, fringe, etc., plots about horizontal axis. Retyping “RPHA” turns this option off. |
| RPVA | Reflect mesh, contour, fringe, etc., plots about vertical axis. Retyping “RPVA” turns this option off. |
| TN r z l | Type node numbers and coordinates of all nodes within window ($r \pm \Delta 2$, $z \pm \Delta 2$). |
| UG | Display undeformed mesh. |
| V | Display material n on graphics display. See command M. |
| VSF | Display material n on graphics display and solid fill elements. |

Mesh Modifications

| | |
|--------|---|
| BACKUP | Restore mesh to its previous state. This command undoes the result of the last command. |
|--------|---|

APPENDIX M

| | |
|---|--|
| BLEN s | Smooth option where $s=0$ and $s=1$ correspond to equipotential and isoparametric smoothing, respectively. By letting $0 \leq s \leq 1$ a combined blending is obtained. |
| CN m r z | Node m has new coordinate (r,z). |
| DEB n f ₁ l ₁ ... f _n l _n | Delete n element blocks consisting of element numbers f ₁ to l ₁ , f ₂ to l ₂ ... , and f _n to l _n inclusive. These elements will be inactive when the calculation resume. |
| DE e ₁ e ₂ | Delete elements e ₁ to e ₂ . |
| DMB n m ₁ m ₂ ... m _n | Delete n material blocks consisting of all elements with material numbers m ₁ , m ₂ ,..., and m _n . These materials will be inactive when the calculations resume. |
| DM n m ₁ m ₂ ... m _n | Delete n materials including m ₁ , m ₂ ,..., and m _n . |
| DZER k d incr nrow | Delete element row where k is the kept element, d is the deleted element, incr is the increment, and nrow is the number of elements in the row. |
| DZLN number n ₁ n ₂ n ₃ ...n _{last} | Delete nodal row where number is the number of nodes in the row and n ₁ , n ₂ , ... n _{last} are the ordered list of deleted nodes. |
| DZNR l j incr | Delete nodal row where l is the first node in the row, j is the last node in the row, and incr is the increment. |
| R | Restore original mesh. |
| S | Smooth mesh of material n. To smooth a subset of elements, a window can be set via the "GSET", "FSET", OR "SETF" commands. Only the elements lying within the window are smoothed. |

Boundary Modifications

| | |
|--------|--|
| A | Display all slidelines. Slave sides are plotted as dashed lines. |
| B | Determine boundary nodes and sides of material n and display boundary with nodes and side numbers. |
| BD m n | Dekink boundary from boundary node m to boundary node n (counterclockwise). |

| | |
|---|--|
| BDS s | Dekink side s. |
| DSL n l ₁ l ₂ ...l _n | Delete n slidelines including slideline numbers l ₁ l ₂ ..., and l _n . |
| ER m n | Equal space in r-direction boundary nodes m to n (counterclockwise). |
| ERS s | Equal space in the r-direction boundary nodes on side s. |
| ES m n | Equal space along boundary, boundary nodes m to n (counterclockwise). |
| ESS s | Equal space along boundary, boundary nodes on side s. |
| EZ m n | Equal space in z-direction boundary nodes m to n (counterclockwise). |
| EZS s | Equal space in the z-direction boundary nodes on side s. |
| MC n | Check master nodes of slideline n and put any nodes that have penetrated through the slave surface back on the slave surface. |
| MD n | Dekink master side of slideline n. After using this command, the SC or MC command is sometimes advisable. |
| MN n | Display slideline n with master node numbers. |
| SC n | Check slave nodes of slideline n and put any nodes that have penetrated through the master surface back on the master surface. |
| SD n | Dekink slave side of slideline n; after using this command, the SC or MC command is sometimes advisable. |
| SLN m n | Equal space boundary nodes between nodes m to n on a straight line connecting node m to n. |
| SLNS n | Equal space boundary nodes along side n on a straight line connecting the corner nodes. |
| SN n | Display slideline n with slave node numbers. |

APPENDIX M

| | |
|----------|---|
| VS m n r | Vary the spacing of boundary nodes m to n such that r is the ratio of the first segment length to the last segment length. |
| VSS s r | Vary the spacing of boundary nodes on side s such that r is the ratio of the first segment length to the last segment length. |

MAZE Line Definitions

| | |
|----------|---|
| B | Determine boundary nodes and sides of material n and display boundary with nodes and side numbers. See command "M". |
| LD n k l | Line definition n for MAZE includes boundary nodes k to l |
| LDS n l | Line definition n for MAZE consists of side number l. |
| M n | Material n is active for the boundary command B. |

Calculation Graphics Display Control Parameters

| | |
|-------------------------------------|--|
| MOLP | Overlay the mesh on the contour, fringe, principal stress, and principal strain plots. Retyping "MOLP" turns this option off. |
| NLOC | Do not plot letters on contour lines. |
| NUMCON n | Plot n contour levels. The default is 9. |
| PLOC | Plot letters on contour lines to identify their levels (default). |
| RANGE r ₁ r ₂ | Set the range of levels to be between r ₁ and r ₂ instead of in the range chosen automatically by LS-DYNA. To deactivate this command, type RANGE 0 0. |

Calculation Graphics Display

| | |
|---|---|
| CONTOUR c n m ₁ m ₂ ...m _n | Contour component number c on n materials including materials m ₁ , m ₂ , ..., m _n . If n is zero, only the outline of material m ₁ with contours is plotted. Component numbers are given in Table 57-1 . |
|---|---|

| | |
|--|--|
| FRINGE c n m ₁ m ₂ ...m _n | Fringe component number c on n materials including m ₁ , m ₂ ,...,m _n . If n is zero, only the outline of material m ₁ with contours is plotted. Component numbers are given in Table 57-1 . |
| IFD n | Begin definition of interface n. If interface n has been previously defined, this command has the effect of destroying the old definition. |
| IFN l m | Include boundary nodes l to m (counterclockwise) in the interface definition. This command must follow the "B" command. |
| IFP c m | Plot component c of interface m. Component numbers are given in Table 57-2 . |
| IFS m | Include side m in the interface definition. Side m is defined for material n by the "B" command. |
| IFVA r _c z _c | Plot the angular location of the interface based on the center point (r _c ,z _c) along the abscissa. Positive angles are measured counterclockwise from the y-axis. |
| IFVS | Plot the distance along the interface from the first interface node along the abscissa (default). |
| LINE c n m ₁ m ₂ ...m _n | Plot variation of component c along line defined with the "NLDF", "PLDF", "NSDF", or the "NSSDF" commands given below. In determining variation, consider n materials including material number m ₁ , m ₂ ,...,m _n . |
| NCOL n | Number of colors in fringe plots is n. The default value for n is 6 which includes colors magenta, blue, cyan, green, yellow, and red. An alternative value for n is 5 which eliminates the minimum value magenta. |
| NLDF n n ₁ n ₂ ...n ₃ | Define line for "LINE" command using n nodes including node numbers n ₁ , n ₂ ,...,n _n . This line moves with the nodes. |
| NSDF m | Define line for "LINE" command as side m. Side m is defined for material n by the "B" command. |
| NSSDF l m | Define line for "LINE" command and that includes boundary nodes l to m (counterclockwise) in the interface |

APPENDIX M

| | |
|---|---|
| | definitions. This command must follow the “B” command. |
| PLDF n r ₁ z ₁ ...r _n z _n | Define line for “LINE” command using n coordinate pairs (r ₁ ,z ₁), (r ₂ ,z ₂), ... (r _n ,z _n). This line is fixed in space. |
| PRIN c n m ₁ m ₂ ...m _n | Plot lines of principal stress and strain in the yz plane on n materials including materials m ₁ , m ₂ ,...,m _n . If n is zero, only the outline of material m ₁ is plotted. The lines are plotted in the principal stress and strain directions. Permissible component numbers in Table M.1 include 0, 5, 6, 100, 105, 106,...,etc. Orthogonal lines of both maximum and minimum stress are plotted if components 0, 100, 200, etc. are specified. |
| PROFILE c n m ₁ m ₂ ...m _n | Plot component c versus element number for n materials including materials m ₁ , m ₂ ,...,m _n . If n is ∅ then component c is plotted for all elements. Component numbers are given in Table M.1. |
| VECTOR c n m ₁ m ₂ ...m _n | Make a vector plot of component c on n materials including materials m ₁ , m ₂ ,...,m _n . If n is zero, only the outline of material m ₁ with vectors is plotted. Component c may be set to “D” and “V” for vector plots of displacement and velocity, respectively. |

| No. | Component | No. | Component |
|---------|---------------------------------------|-----|---|
| 1 | y | 21* | ln (V/Vo) (volumetric strain) |
| 2 | z | 22* | y-displacement |
| 3 | hoop | 23* | z-displacement |
| 4 | yz | 24* | maximum displacement |
| 5 | maximum principal | 25* | y-velocity, y-heat flux |
| 6 | minimum principal | 26* | z-velocity, y-heat flux |
| 7 | von Mises (Appendix A) | 27* | maximum velocity, maximum heat flux |
| 8 | pressure or average strain | 28 | ij normal |
| 9 | maximum principal - minimum principal | 29 | jk normal |
| 10 | y minus hoop | 30 | kl normal |
| 11 | maximum shear | 31 | li normal |
| 12 | ij and kl normal (see appendix D) | 32 | ij shear |
| 13 | jk and li normal | 33 | jk shear |
| 14 | ij and kl shear | 34 | kl shear |
| 15 | jk and li shear | 35 | li shear |
| 16 | y-deviatoric | 36* | relative volume V/Vo |
| 17 | z-deviatoric | 37* | Vo/V-1 |
| 18 | hoop-deviatoric | 38* | bulk viscosity, Q |
| 19* | effective plastic strain | 39* | P + Q |
| 20* | temperature/internal energy density | 40* | density |
| 41*-70* | element history variables | | |
| 71* | r-peak acceleration | 76* | peak value of min in plane prin. stress |
| 72* | z-peak acceleration | 77* | peak value of maximum hoop stress |
| 73* | r-peak velocity | 78* | peak value of minimum hoopstress |
| 74* | z-peak velocity | 79* | peak value of pressure |
| 75* | peak value of max. in plane | | prin. stress |

Table 57-1. Component numbers for element variables. By adding 100, 200 300, 400, 500 and 600 to the component numbers not followed by an asterisk, component numbers for infinitesimal strains, lagrange strains, almansi strains, strain rates, extensions, and residual strain are obtained. Maximum and minimum principal stresses and strains are in the rz plane. The corresponding hoop quantities must be examined to determine the overall extremum. ij, jk, etc. normal components are normal to the ij, jk, etc side. The peak value database must be flagged on Control Card 4 in columns 6-10 or components 71-79 will not be available for plotting.

APPENDIX M

| No. | Component |
|-----|------------------|
| 1 | pressure |
| 2 | shear stress |
| 3 | normal force |
| 4 | tangential force |
| 5 | y-force |
| 6 | z-force |

Table 57-2. Component numbers for interface variables. In axisymmetric geometries the force is per radian.

Cursor Commands

| | |
|----------|--|
| DBD a b | Use cursor to define points a and b on boundary. Dekink boundary starting at a, moving counterclockwise, and ending at b. |
| DCN a b | Use cursor to define points a and b. The node closest to point a will be moved to point b. |
| DCSN n a | Move nodal point n to point a defined by the cursor. |
| DCNM a b | Use cursor to define points a and b. The node at point a is given the coordinate at point b. |
| DER a b | Use cursor to define points a and b on boundary. Equal space nodes in r-direction along boundary starting at a, moving counterclockwise, and ending at b. |
| DES a b | Use cursor to define points a and b on boundary. Equal space nodes along boundary starting at a, moving counterclockwise, and ending at b. |
| DEZ a b | Use cursor to define points a and b on boundary. Equal space nodes in z-direction along boundary starting at a, moving counterclockwise, and ending at b. |
| DTE a b | Use cursor to define points a and b on the diagonal of a window. The element numbers and coordinates of elements lying within the window are typed on the terminal. |
| DTN a b | Use cursor to define points a and b on the diagonal of a window. The node numbers and coordinates of nodal points lying within the window are typed on the terminal. |

| | |
|-----------|---|
| DTNC a | Use cursor to define point a. The nodal point number and nodal coordinates of the node lying closest to point a will be printed. |
| DVS a b r | Use cursor to define points a and b on boundary. Variable space nodes along boundary starting at a, moving counter-wise, and ending at b. The ratio of the first segment length to the last segment length is give by r (via terminal). |
| DZ a b | Use cursor to define points a and b on the diagonal of a window for zooming. |
| DZOUT a b | Enter two points with the cursor to define the window. The ratio of the current window with the specified window determines the picture size reduction. |
| DZZ a | Use cursor to define point a and zoom in at this point. The new window is .15 as large as the previous window. The zoom factor can be reset by the crzf command for the .15 default. |
| DZZO a | Zoom out at point a by enlarging the picture two times. |

APPENDIX N: Rigid-Body Dummies

The two varieties of rigid body dummies available in LS-DYNA are described in this appendix. These are generated internally by including the appropriate *COMPONENT keyword. A description of the GEBOD dummies begins on this page and the HYBRID III family on page N.7.

GEBOD Dummies

Rigid body dummies can be generated and simulated within LS-DYNA using the keyword *COMPONENT_GEBOD. Physical properties of these dummies draw upon the GEBOD database [Cheng et al. 1994] which represents an extensive measurement program conducted by Wright-Patterson AFB and other agencies. The differential equations governing motion of the dummy are integrated within LS-DYNA separate from the finite element model. Interaction between the dummy and finite element structure is achieved using contact interfaces (see *CONTACT_GEBOD).

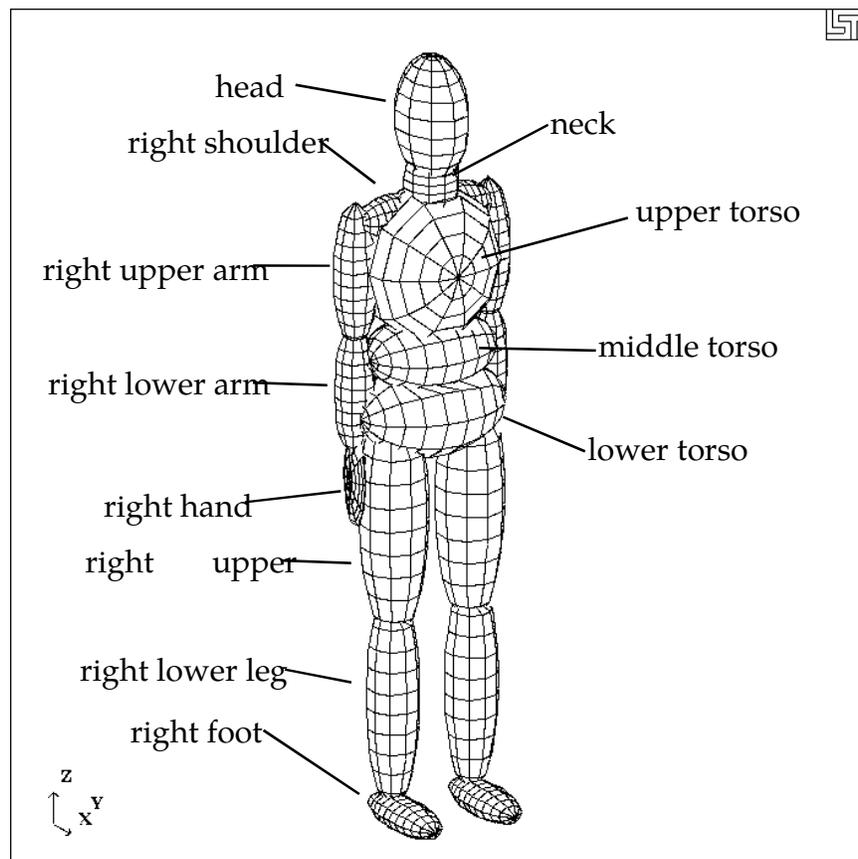

Figure 58-1. 50th percentile male dummy in the nominal position.

APPENDIX N

The dynamical system representing a dummy is comprised of fifteen rigid bodies (segments) and include: lower torso, middle torso, upper torso, neck, head, upper arms, forearms/hands, upper legs, lower legs, and feet. Ellipsoids are used for visualization and contact purposes. Shown in [Figure 58-1](#) is a 50th percentile male dummy generated using the keyword command *COMPONENT_GEBOD_MALE. Note that the ellipsoids representing the shoulders are considered to be part of the upper torso segment and the hands are rigidly attached to the forearms.

Each of the rigid segments which make up the dummy is connected to its neighbor with a joint which permits various relative motions of the segments. Listed in the [Table 58-2](#) are the joints and their applicable degrees of freedom.

| Joint Name | Degree(s) of Freedom | | |
|------------|-------------------------|--------------------------------|-----------------------------|
| | 1 st | 2 nd | 3 rd |
| pelvis | lateral flexion (x) | forward flexion (y) | torsion (z) |
| waist | lateral flexion (x) | forward flexion (y) | torsion (z) |
| lower neck | lateral flexion (x) | forward flexion (y) | torsion (z) |
| upper neck | lateral flexion (x) | forward flexion (y) | torsion (z) |
| shoulders | abduction-adduction (x) | internal-external rotation (z) | flexion-extension (y) |
| elbows | flexion-extension (y) | n/a | n/a |
| hips | abduction-adduction (x) | medial-lateral rotation (z) | flexion-extension (y) |
| knees | flexion-extension (y) | n/a | n/a |
| ankles | inversion-eversion (x) | dorsi-plantar flexion (y) | medial-lateral rotation (z) |

Table 58-2. Joints and associated degrees of freedom. Local axes are in parentheses.

Orientation of a segment is effected by performing successive right-handed rotations of that segment relative to its parent segment - each rotation corresponds to a joint degree of freedom. These rotations are performed about the local segment axes and the sequence is given in [Table 58-2](#). For example, the left upper leg is connected to the lower torso by the left hip joint; the limb is first abducted relative to lower torso, it then undergoes lateral rotation, followed by extension. The remainder of the lower extremity (lower leg and foot) moves with the upper leg during this orientation process.

By default all joints are assigned stiffnesses, viscous characteristics, and stop angles which should give reasonable results in a crash simulation. One or all default values of a joint may be altered by applying the *COMPONENT_GEBOD_JOINT_OPTION command to the joint of interest. The default shape of the resistive torque load curve used by all joints is shown in [Figure 58-6](#). A scale factor is applied to this curve to obtain the proper stiffness relationship. Listed in [Table 58-3](#) are the default values of joint characteristics for dummies of all types and sizes. These values are given in the

APPENDIX N

English system of units; the appropriate units are used if a different system is specified in card 1 of *COMPONENT_GEBOD_OPTION.

| joint degrees of freedom | load curve scale factor (in·lbf) | damping coef. (in·lbf·s/rad) | low stop angle (degrees) | high stop angle (degrees) | neutral angle (degrees) |
|--------------------------|----------------------------------|------------------------------|--------------------------|---------------------------|-------------------------|
| pelvis - 1 | 65000 | 5.77 | -20 | 20 | 0 |
| pelvis - 2 | 65000 | 5.77 | -20 | 20 | 0 |
| pelvis - 3 | 65000 | 5.77 | -5 | 5 | 0 |
| waist - 1 | 65000 | 5.77 | -20 | 20 | 0 |
| waist - 2 | 65000 | 5.77 | -20 | 20 | 0 |
| waist - 3 | 65000 | 5.77 | -35 | 35 | 0 |
| lower neck - 1 | 10000 | 5.77 | -25 | 25 | 0 |
| lower neck - 2 | 10000 | 5.77 | -25 | 25 | 0 |
| lower neck - 3 | 10000 | 5.77 | -35 | 35 | 0 |
| upper neck - 1 | 10000 | 5.77 | -25 | 25 | 0 |
| upper neck - 2 | 10000 | 5.77 | -25 | 25 | 0 |
| upper neck - 3 | 10000 | 5.77 | -35 | 35 | 0 |
| l. shoulder - 1 | 100 | 5.77 | -30 | 175 | 0 |
| r. shoulder - 1 | 100 | 5.77 | -175 | 30 | 0 |
| shoulder - 2 | 100 | 5.77 | -65 | 65 | 0 |
| shoulder - 3 | 100 | 5.77 | -175 | 60 | 0 |
| elbow - 1 | 100 | 5.77 | 1 | -140 | 0 |
| l. hip - 1 | 10000 | 5.77 | -25 | 70 | 0 |
| r. hip - 1 | 10000 | 5.77 | -70 | 25 | 0 |
| hip - 2 | 10000 | 5.77 | -70 | 70 | 0 |
| hip - 3 | 10000 | 5.77 | -140 | 40 | 0 |
| knee - 1 | 100 | 5.77 | -1 | 120 | 0 |
| l. ankle - 1 | 100 | 5.77 | -30 | 20 | 0 |
| l. ankle - 1 | 100 | 5.77 | -20 | 30 | 0 |
| ankle - 2 | 100 | 5.77 | -20 | 45 | 0 |
| ankle - 3 | 100 | 5.77 | -30 | 30 | 0 |

Table 58-3. Default joint characteristics for all dummies.

APPENDIX N

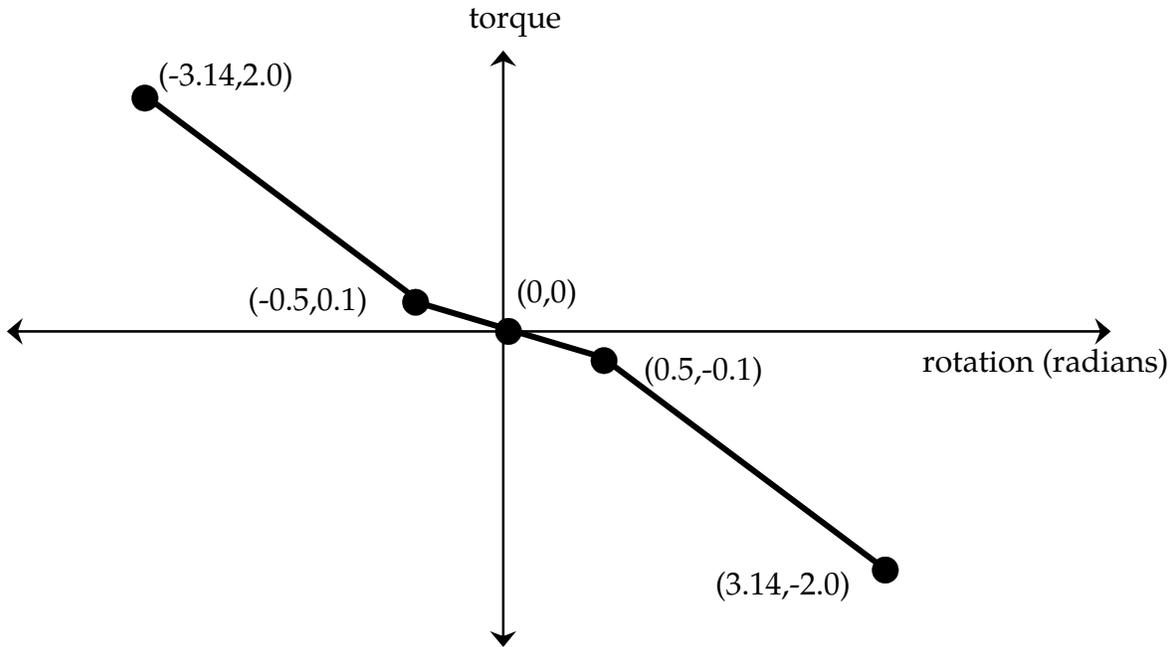

Figure 58-4 Characteristic torque curve shape used by all joints.

The dummy depicted in [Figure 58-1](#) appears in what is referred to as its "nominal" position. In this position the dummy is standing upright facing in the positive x direction and the toe-to-head direction points in positive z. Additionally, the dummy's hands are at the sides with palms facing inward and the centroid of the lower torso is positioned at the origin of the global coordinate system. Each of the dummy's segments has a local coordinate system attached to it and in the nominal position all of the local axes are aligned with the global axes.

When performing a simulation involving a *COMPONENT_GEBOD dummy, a positioning file named "gebod.did" must reside in the directory with the LS-DYNA input file; here the extension *did* is the dummy ID number, see card 1 of *COMPONENT_GEBOD_OPTION. The contents of a typical positioning file is shown in [Table 58-5](#); it consists of 40 lines formatted as (59a1,e30.0). All of the angular measures are input as degrees, while the lower torso global positions depend on the choice of units in card 1 of *COMPONENT_GEBOD_OPTION. Setting all of the values in this file to zero yields the so-called "nominal" position.

Table 58-5. Typical contents of a dummy positioning file.

| | | |
|-------------|----------------------------|-------|
| lower torso | centroid global x position | 0.0 |
| lower torso | centroid global y position | 0.0 |
| lower torso | centroid global z position | 0.0 |
| total body | global x rotation | 0.0 |
| total body | global y rotation | -20.0 |
| total body | global z rotation | 180.0 |

| | | | |
|----------------|----------------------------|----------------|-------|
| pelvis | lateral flexion | + = tilt right | 0.0 |
| pelvis | forward flexion | + = lean fwd | 0.0 |
| pelvis | torsion | + = twist left | 0.0 |
| waist | lateral flexion | + = tilt right | 0.0 |
| waist | forward flexion | + = lean fwd | 0.0 |
| waist | torsion | + = twist left | 0.0 |
| lower neck | lateral flexion | + = tilt right | 0.0 |
| lower neck | forward flexion | + = nod fwd | 0.0 |
| lower neck | torsion | + = twist left | 0.0 |
| upper neck | lateral flexion | + = tilt right | 0.0 |
| upper neck | forward flexion | + = nod fwd | 0.0 |
| upper neck | torsion | + = twist left | 0.0 |
| left shoulder | abduction-adduction | + = abduction | 30.0 |
| left shoulder | internal-external rotation | + = external | -10.0 |
| left shoulder | flexion-extension | - = fwd raise | -40.0 |
| right shoulder | abduction-adduction | - = abduction | -30.0 |
| right shoulder | internal-external rotation | - = external | 10.0 |
| right shoulder | flexion-extension | - = fwd raise | -40.0 |
| left elbow | flexion-extension | + = extension | -60.0 |
| right elbow | flexion-extension | + = extension | -60.0 |
| left hip | abduction-adduction | + = abduction | 0.0 |
| left hip | medial-lateral rotation | + = lateral | 0.0 |
| left hip | flexion-extension | + = extension | -80.0 |
| right hip | abduction-adduction | - = abduction | 0.0 |
| right hip | medial-lateral rotation | - = lateral | 0.0 |
| right hip | flexion-extension | + = extension | -80.0 |
| left knee | flexion-extension | + = flexion | 50.0 |
| right knee | flexion-extension | + = flexion | 50.0 |
| left ankle | inversion-eversion | + = eversion | 0.0 |
| left ankle | dorsi-plantar flexion | + = plantar | 0.0 |
| left ankle | medial-lateral rotation | + = lateral | 0.0 |
| right ankle | inversion-eversion | - = eversion | 0.0 |
| right ankle | dorsi-plantar flexion | + = plantar | 0.0 |
| right ankle | medial-lateral rotation | - = lateral | 0.0 |

In [Figure 58-6](#) the 50th percentile male dummy is shown in a seated position and some of its joints are labeled. The file listed in [Table 58-5](#) was used to put the dummy into the position shown. Note that the dummy was first brought into general orientation by setting nonzero values for two of the lower torso local rotations. This is accomplished by performing right-handed rotations successively about local axes fixed in the lower torso, the sequence of which follows: the first about local x, next about local y, and the last about local z. The dummy in [Figure 58-6](#) was made to pitch backward by setting

APPENDIX N

"total body global y rotation" equal to -20. Setting the "total body global z rotation" equal to 180 caused the dummy to rotate about the global z-axis and face in the -x direction.

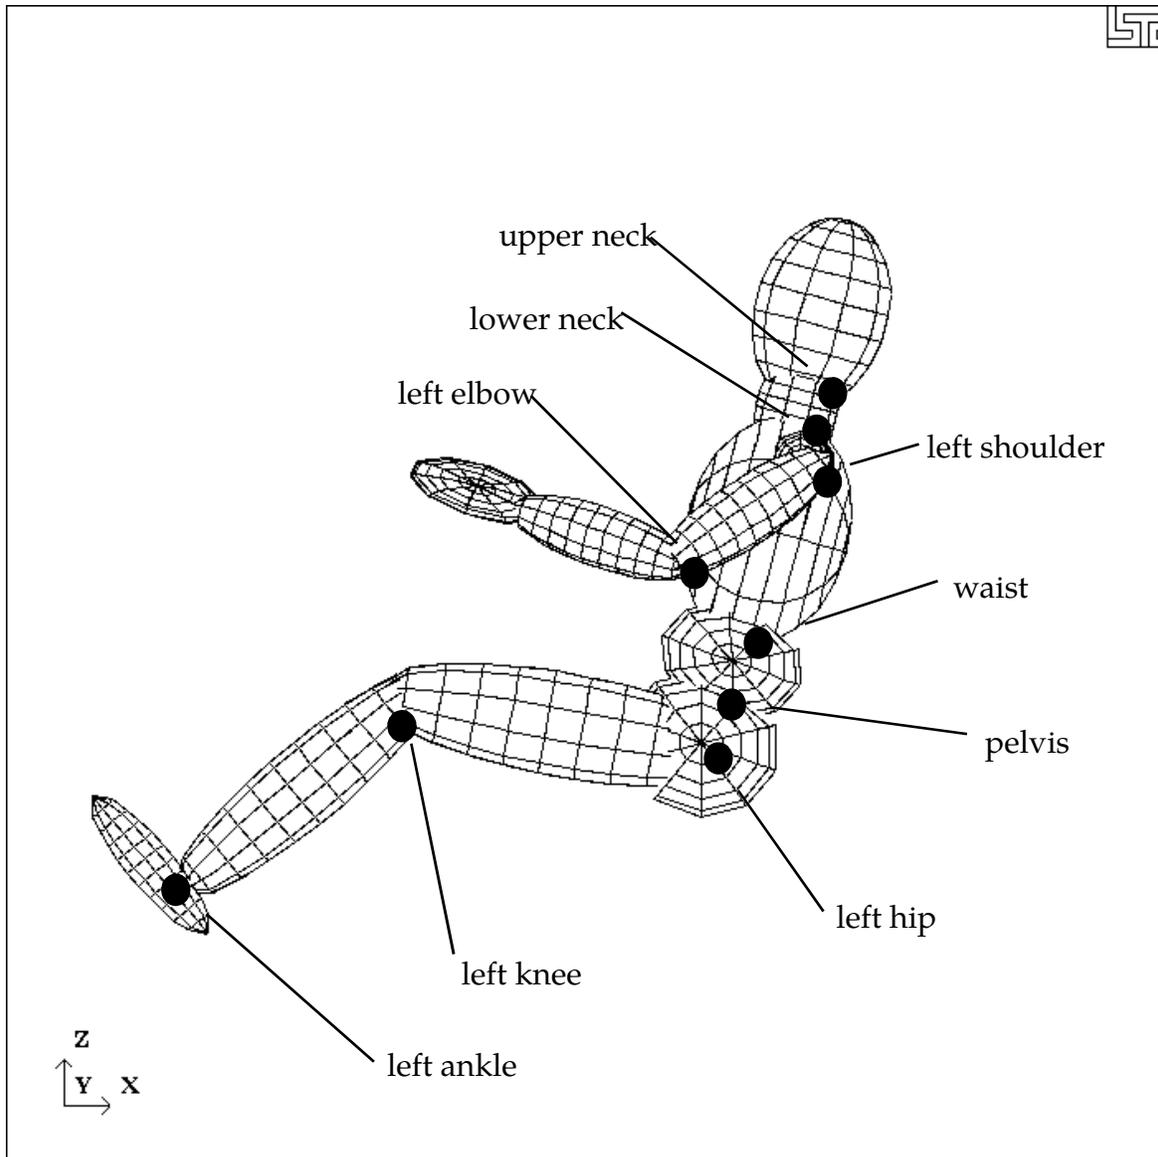

Figure 58-6. Dummy seated using the file listed in [Table 58-5](#).

HYBRID III Dummies

A listing of applicable joint degrees of freedom of the Hybrid III dummy is given below.

| Joint Name | Degree(s) of Freedom | | |
|--------------|-------------------------|-----------------------------|---------------------------|
| | 1st | 2nd | 3rd |
| lumbar | flexion (y) | torsion (z) | |
| lower neck | flexion (y) | torsion (z) | |
| upper neck | flexion (y) | torsion (z) | |
| shoulders | flexion-extension (y) | abduction-adduction (x) | n/a |
| elbows | flexion-extension (y) | n/a | n/a |
| wrists | flexion-extension (x) | n/a | n/a |
| hips | abduction-adduction (x) | medial-lateral rotation (z) | flexion-extension (y) |
| knees | flexion-extension (y) | n/a | n/a |
| ankles | inversion-eversion (x) | medial-lateral rotation (z) | dorsi-plantar flexion (y) |
| sternum | translation (x) | rotation (y) | rotation (z) |
| knee sliders | translation (z) | | |

Table 58-7. Joints and associated degrees of freedom. Local axes are in parentheses.

Joint springs of the *COMPONENT_HYBRIDIII dummies are formulated in the following manner.

$$\begin{aligned}
 T &= a_{lo}(q - q_{lo}) + b_{lo}(q - q_{lo})^3, & q \leq q_{lo} \\
 T &= a_{hi}(q - q_{hi}) + b_{hi}(q - q_{hi})^3, & q \geq q_{hi} \\
 T &= 0, & q_{lo} < q < q_{hi}
 \end{aligned}$$

Where,

T is the joint torque

q is the joint generalized coordinate

a_{lo} and b_{lo} are the linear and cubic coefficients, respectively, for the low regime

a_{hi} and b_{hi} are the linear and cubic coefficients, respectively, for the high regime

q_{lo} and q_{hi} are the activation values for the low and high regimes, respectively

APPENDIX O: LS-DYNA MPP User Guide

This is a short user's guide for the MPP version of LS-DYNA. For a general guide to the capabilities of LS-DYNA and a detailed description of the input, consult the LS-DYNA User's Manual. If you have questions about this guide, find errors or omissions in it, please email manual@lstc.com.

SUPPORTED FEATURES

The only input formats currently supported are 920 and later, including keyword input. Models in any of the older formats will need to be converted to one of these input formats before they can be run with the current version of LS-DYNA for massively parallel processors, mpp.

The large majority of LS-DYNA options are available on MPP computers. Those that are not supported are being systematically added. Unless otherwise noted here, all the options of LS-DYNA version 93x are supported by MPP/LS-DYNA.

Here is the list of **unsupported** features:

- *BOUNDARY_THERMAL_WELD
- *BOUNDARY_USA_SURFACE
- *CONTACT_1D
- *DATABASE_AVS
- *DATABASE_MOVIE
- *DATABASE_MPGS
- *LOAD_SUPERPLASTIC_OPTION
- *USER
- *TERMINATION_NODE

CONTACT INTERFACES

MPP/LS-DYNA uses a completely redesigned, highly parallel contact algorithm. The contact options currently **unsupported** include:

APPENDIX O

*CONTACT_FORCE_TRANSDUCER_CONSTRAINT

Because these options are all supported via the new, parallel contact algorithms, slight differences in results may be observed as compared to the serial and SMP versions of LS-DYNA. Work has been done to minimize these differences, but they may still be evident in some models.

For each of the supported CONTACT_control cards, there is an optional string_MPP which can be appended to the end. Adding these characters triggers the reading of a new control card immediately following (but after the TITLE card, if any). See the section on *CONTACT for details of the parameters and their meanings.

OUTPUT FILES AND POST-PROCESSING

For performance reasons, many of the ASCII output files normally created by LS-DYNA have been combined into a new binary format used by MPP/LS-DYNA. There is a post-processing program l2a, which reads this binary database of files and produces as output the corresponding ASCII files. The new binary files will be created in the directory specified as the global directory in the pfile (See section pfile). The files (up to one per processor) are named binout*nnnn*, where *nnnn* is replaced by the four-digit processor number. To convert these files to ASCII simply feed them to the l2a program like this:

l2a binout*

LS-PREPOST is able to read the binout files directly, so conversion is not required, it is provided for backward compatibility.

The supported ASCII files are:

- *DATABASE_SECFORC
- *DATABASE_RWFORC
- *DATABASE_NODOUT
- *DATABASE_NODOUTHF
- *DATABASE_ELOUT
- *DATABASE_GLSTAT
- *DATABASE_DEFORC
- *DATABASE_MATSUM
- *DATABASE_NCFORC

*DATABASE_RCFORC
*DATABASE_SPCFORC
*DATABASE_SWFORC
*DATABASE_DEFGEO
*DATABASE_ABSTAT
*DATABASE_NODOFR
*DATABASE_BNDOUT
*DATABASE_GCEOUT
*DATABASE_RBDOUT
*DATABASE_SLEOUT
*DATABASE_JNTFORC
*DATABASE_SBTOUT
*DATABASE_SPHOUT
*DATABASE_TPRINT

Some of the normal LS-DYNA files will have corresponding collections of files produced by MPP/LS-DYNA, with one per processor. These include the d3dump files (new names = d3dump.nnnn), the messag files (now mesnnnn) and others. Most of these will be found in the local directory specified in the pfile.

The format of the d3plot file has not been changed. It will be created in the global directory, and can be directly handled with your current graphics post-processor.

PARALLEL SPECIFIC OPTIONS

There are a few new command line options that are specific to the MPP version of LS-DYNA.

In the serial and SMP versions of LS-DYNA, the amount of memory required to run the problem can be specified on the command line by adding “memory=XXX”, where XXX is the number of words of memory to be allocated. For the MPP code, this will result in each processor allocating XXX words of memory. If pre-decomposition has not been performed, one processor must perform the decomposition of the problem. This can require substantially more memory than will be required once execution has started. For this reason, there is a second memory command line option, “memory2=YYY”. If

APPENDIX O

used together with adding “memory=XXX”, the decomposing processor will allocate XXX words of memory, and all other processors will allocate YYY words of memory.

For example, in order to run a 250,000 element crash problem on 4 processors, you might need memory=80m and memory2=20m. To run the same problem on 16 processors, you still need memory=80m, but can set memory2=6m. The value for *memory2* drops nearly linearly with the number of processors used to run the program, which works well for shared-memory systems.

Execution of the implicit solver in MPP requires a balance of memory across all of the processes. The user should not use memory2= specification for runs involving the implicit solver. If the model decomposition cannot be performed for the given memory= specification, one can try a pre-decomposition but the user would be advised to use a compute cluster with more real memory. It is suggested that the memory= specification be such to use no more than 75% of the real memory available to that process. On a compute cluster with each compute node having 48 Gbytes of memory and using 8 MPI processes, there is only 6 Gbytes of real memory per process. Converting to 8 byte words and using only the suggested 75% would have memory=560M as the maximum specification.

The full deck restart capability is supported by the MPP version of LS-DYNA, but in a manner slightly different than the SMP code. Each time a restart dump file is written, a separate restart file is also written with the base name D3FULL. For example, when the third restart file d3dump03 is written (one for each processor, d3dump03.0000, d3dump03.0001, etc), there is also a single file written named d3full03. This file is required in order to do a full deck restart and the d3dump files are not used in this case by the MPP code. In order to perform a full deck restart with the MPP code, you first must prepare a full deck restart input file as for the serial/SMP version. Then, instead of giving the command line option r=d3dump03 you would use the special option n=d3full03. The presence of this command line option tells the MPP code that this is a restart, not a new problem, and that the file d3full03 contains the geometry and stress data carried over from the previous run.

PFILE

There is a new command line option: p = pfile. pfile contains MPP specific parameters that affect the execution of the program. The file is split into sections, with several options in each section. Currently, these sections: **directory**, **decomposition**, **contact**, and **general** are available. First, here is a sample pfile:

```
directory {
    global rundir
    local /tmp/rundir
}
contact {
```

```
        inititer 3
    }
```

The file is case insensitive and free format input. The sections and options currently supported are:

directory: Holds directory specific options

transfer_files

If this option is given, then processor 0 will write all output and restart files to the **global** directory (see “global” below), and scratch files to the **local** directory. All other processors will write all data to their **local** directory. At normal termination, all restart and output files will be copied from the processor specific **local** directories to the **global** directory. Also, if this is a restart from a dump file, the dump files will be distributed to the processors from the **global** directory. With this option enabled, there is no need for the processors to have shared access to a single disk for output – all files will be transferred as needed to and from the **global** directory.

Default = disabled.

global_path

Path to a directory where program output should be written. If **transfer_files** is not given, this directory needs to be accessible to all processors – otherwise it is only accessed by processor 0. This directory will be created if necessary.

Default = current working directory

global_message_files

If this option appears, the message files are written in the global directory rather than the local directory

Default = disabled (message files go in the local directory)

local_path

Path to a processor specific local directory for scratch files. This directory will be created if necessary. This should be a local disk on each processor, for performance reasons.

Default = global_path

rmlocal

If this option is given and **transfer_files** is active, the program attempts to clean up the **local** directories on each processor. In particular, it deletes files that are successfully transferred back to the **global** directory, and removes the **local** directory if it was created. It will not delete any files if there is a failure during file copying, nor will it delete directories it did not create.

Default = disabled

repository_path

APPENDIX O

Path to a safe directory accessible from processor 0. This directory will be created if necessary. This is intended to be used as a safekeeping/backup of files during execution and should only be used if **transfer_files** is also given. If this directory is specified then the following actions occur:

- At program start up, any required files (d3dump, binout, etc) that cannot be located in the **global** directory are looked for in the **repository** for copying to the **local** processor directories.
- Important output files (d3dump, runrsf, d3plot, binout and others) are synchronized to the repository regularly. That is, every time one of these files is updated on the node local or the global directories, a synchronized copy is updated in the repository.

The intention is that the repository be on a redundant disk, such as NAS, to allow restarting the problem if a hardware failure should occur on the machine running the problem. It must be noted that some performance penalty must be paid for the extra communication and I/O. Effort has been made to minimize this overhead, but this option is not recommended for general use.

Default = unspecified

decomposition: Holds decomposition specific options

file *filename*

The name of the file that holds the decomposition information. This file will be created in the current working directory if it does not exist. If this option is not specified, MPP/LS-DYNA will perform the decomposition.

Default = None

numproc *n*

The problem will be decomposed for n processors. If $n > 1$ and you are running on 1 processor, or if the number of processors you are running on does not evenly divide n , then execution terminates immediately after decomposition. Otherwise, the decomposition file is written and execution continues. For a decomposition only run, both **numproc** and **file** should be specified.

Default = the number of processors you are running on.

method *name*

Currently, there are two decomposition methods supported, namely *rcb* and *greedy*. Method *rcb* is Recursive Coordinate Bisection. Method *greedy* is a simple neighborhood expansion algorithm. The impact on overall runtime is problem dependent, but *rcb* generally gives the best performance.

Default = rcb

region *rx ry rz sx sy sz c2r s2r 3vec mat*

See the section below on Special Decompositions for details about these decomposition options.

show

If this option appears in the decomposition section, the d3plot file is doctored so that the decomposition can be viewed with the post processor. Displaying material 1 will show that portion of the problem assigned to processor 0, and so on. The problem will not actually be run, but the code will terminate once the initial d3plot state has been written.

rcblog filename

This option is ignored unless the decomposition method is RCB. A record is written to the indicated file recording the steps taken during decomposition. This is an ascii file giving each decomposition **region** (see the section on Special Decompositions) and the location of each subdivision for that **region**. Except for the addition of this decomposition information, the file is otherwise equivalent to the current pfile. Thus it can be used directly as the pfile for a subsequent problem, which will result in a decomposition as similar as possible between the two runs. For example, suppose a simulation is run twice, but the second time with a slightly different mesh. Because of the different meshes the problems will be distributed differently between the processors, resulting in slightly different answers due to roundoff errors. If an rcblog is used, then the resulting decompositions would be as similar as possible.

vspeed

If this option is specified a brief measurement is taken of the performance of each processor by timing a short floating point calculation. The resulting information is used during the decomposition to distribute the problem according to the relative speed of the processors. This might be of some use if the cluster has machines of significantly different speed.

automatic

If this option is given, an attempt is made to automatically determine a reasonable decomposition, primarily based on the initial velocity of nodes in the model. Use of the **show** option is recommended to verify a reasonable decomposition.

aledist

Distribute ALE elements to all processors.

dcmem n

It may be in some cases that the memory requirements during the first phase of decomposition are too high. If that is found to be the case (if you get out of memory errors during decomposition phase 1), then this may provide a work around. Specifying a value n here will cause some routines to process the model in blocks of n items, when normal processing would read the whole set (of nodes, elements, whatever) all at once. This will reduce memory requirements at the cost of greater communication overhead. Most users will not need this option. Values in the range of 10,000 to 50,000 would be reasonable.

APPENDIX O

dunreflc

Time dependent load curves are usually applied to the following boundary or loading conditions on each node. By default, those curves are copied to all MPP subdomain without checking for the presence of that node in the domain or not. The curves are evaluated every cycle and may consume substantial CPU time. This command will remove curves which are not referenced in the MPP subdomain for the following keywords.

*BOUNDARY_PRESCRIBED_MOTION_NODE

*LOAD_NODE

*LOAD_SHELL_ELEMENT

*LOAD_THERMAL_VARIABLE_NODE

timing_start n

Begin timing of element calculations on cycle *n*. The appearance of this option will trigger the generation of a file named DECOMP_TIMINGS.OUT during normal termination. This file will contain information about the actual time spent doing element calculations, broken down by part.

timing_end n

End timing of element calculations on cycle *n*. A reasonable value is probably `timing_start + 50` or `100`.

timing_file filename

The file filename is assumed to be the output file DECOMP_TIMINGS.OUT from a previous run of this or a similar model. The computational cost of each part that appears in this file is then used during the decomposition instead of the built in internal value for that part. Matching is based strictly on the user part ID. The first two lines of the file are skipped, and only the first two entries on each of the remaining lines are relevant (the part ID and the cost per element).

contact:

This section has been largely replaced by the `_MPP` option on the normal contact card. The only remaining useful option here is:

alebkt n

Sets the bucket sort frequency for FSI (fluid structure interaction) to once every *n* cycles.

default = 50

general: Holds general options

lstc_reduce

If this option appears, LSTC's own reduce routine is used to get consistent summation of floating point data among processors. See also, *CONTROL_MPP_IO_LSTC_REDUCE which has the same effect..

nodump

If this option appears, all restart dump file writing will be suppressed: d3dump, runrsf, and d3full files will not be written

nofull

If this option appears, writing of d3full (full deck restart) files will be suppressed.

nod3dump

If this option appears, writing of d3dump and runrsf files will be suppressed.

runrsfonly

If this option appears, writing of d3dump files will not occur – runrsf files will be written instead. Any time a d3dump OR runrsf file would normally be written, a runrsf file will be written.

swapbytes

If this option appears, the d3plot and interface component analysis files are written in swapped byte ordering.

nobeamout

Generally, whenever a beam, shell, or solid element fails, and element failure report is written to the d3hsp and message files. This can generate a lot of output. If this option appears, the element failure report is suppressed.

Special Decompositions:

These options appear in the “decomposition” section of the pfile and are only valid if the decomposition method is **rcb**. The rcb decomposition method works by recursively dividing the model in half, each time slicing the current piece of the model perpendicularly to one of the three coordinate axes. It chooses the axis along which the current piece of the model is longest. The result is that it tends to generate cube shaped domains aligned along the coordinate axes. This is inherent in the algorithm, but is often not the behavior desired.

This situation is addressed by providing a set of coordinate transformation functions which are applied to the model before it is decomposed. The resulting deformed geometry is then passed to the decomposition algorithm, and the resulting domains are mapped back to the undeformed model. As a simple example, suppose you wanted rectangular domains aligned along a line in the xy plane, 30 degrees from the x axis,

APPENDIX O

and twice as long along this line as in the other two dimensions. If you applied these transformations:

```
sx 0.5
rz -30
```

then you would achieve the desired effect.

Furthermore, it may be desirable for different portions of the model to be decomposed differently. It is now possible to specify different regions of the model to be decomposed with different transformations. The general form for a special decomposition would look like this:

```
decomposition {
    region { <region specifiers> <transformation> <grouping> }
    region { <region specifiers> <transformation> <grouping> }
    <transformation>
}
```

Where the region specifiers are logical combinations of **box**, **sphere**, **cylinder**, **parts**, and **silist**.

The transformation is a series of **sx**, **sy**, **sz**, **rx**, **ry**, **rz**, **c2r**, **s2r**, **3vec**, and **mat**. The grouping is either **lumped** or empty. The portion of the model falling in the first region will be decomposed according to the given transformation. Any remaining part of the model in the second region will then be treated, and finally anything left over will be decomposed according to the final transformation. Any number of regions may be given, including 0. Any number of transformations may be specified. They are applied to the region in the order given.

The region specifiers are:

box xmin xmax ymin ymax zmin zmax

A box with the given extents.

sphere xc yc zc r

The sphere centered at (xc,yc,zc) and having radius r. If r is negative it is treated as infinite.

cylinder xc yc zc ax ay az r d

A cylinder with center at (xc,yc,zc) and radius r, extending out in the direction of (ax,ay,az) for a distance of d. If d is 0, the cylinder is infinite in both directions.

parts n1 n2 n3 n4....

All parts whose user id matches one of the given values are included in the region. Any number of values may be given.

partsets n1 n2 n3 n4....

All partsets whose user id matches one of the given values will have all of their parts included in the region. Any number of values may be given.

silist n1 n2 n3 n4....

All elements involved in a contact interface whose user id matches one of the given values are included in the region.

The transformations available are:

local

This is only useful in conjunction with the *CONTROL_MPP_PFILE keyword option, when used inside a file included via *INCLUDE_TRANSFORM. At this point in the region processing, a transformation is inserted to invert the transformation used by *INCLUDE_TRANSFORM. The effect is that if this option appears before any other transformation options, all those options (and the subsequent decomposition) are performed in the coordinate system of the include file itself, not the global coordinate system..

sx t

scale the current x coordinates by t .

sy t

scale the current y coordinates by t .

sz t

scale the current z coordinates by t .

rx t

rotate around the current x axis by t degrees.

ry t

rotate around the current y axis by t degrees.

rz t

rotate around the current z axis by t degrees.

txyz x y z

translate by (x,y,z) .

mat m11 m12 m13 m21 m22 m23 m31 m32 m33

transform the coordinates by matrix multiplication:

$$\text{Transformed Coordinates} = \begin{bmatrix} x' \\ y' \\ z' \end{bmatrix} = \begin{bmatrix} m_{11} & m_{12} & m_{13} \\ m_{21} & m_{22} & m_{23} \\ m_{31} & m_{32} & m_{33} \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix}$$

APPENDIX O

3vec v11 v12 v13 v21 v22 v23 v31 v32 v33

Transform the coordinates by the inverse of the transpose matrix:

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} v_{11} & v_{21} & v_{31} \\ v_{12} & v_{22} & v_{32} \\ v_{13} & v_{23} & v_{33} \end{bmatrix} \begin{bmatrix} x' \\ y' \\ z' \end{bmatrix} \\ = \mathbf{V}^T \times \text{transformed coordinates}$$

This appears complicated, but in practice is very intuitive: instead of decomposing into cubes aligned along the coordinate axes, rcb will decompose into parallelepipeds whose edges are aligned with the three vectors (v11, v12, v13), (v21, v22, v23), and (v31, v32, v33). Furthermore, the relative lengths of the edges of the decomposition domains will correspond to the relative lengths of these vectors.

C2R x0 y0 z0 vx1 vy1 vz1 vx2 vy2 vz2

The part is converted into a cylindrical coordinate system with origin at (x0, y0, z0), cylinder axis (vx1, vy1, vz1) and theta = 0 along the vector (vx2, vy2, vz2). You can think of this as tearing the model along the (vx2, vy2, vz2) vector and unwrapping it around the (vx1, vy1, vz1) axis. The effect is to create decomposition domains that are “cubes” in cylindrical coordinates: they are portions of cylindrical shells. The actual transformation is:

$$\text{new}(x, y, z) = \text{cylindrical coordinates}(r, \theta, z)$$

Knowing the order of the coordinates is important if combining transformations, as in the example below.

S2R x0 y0 z0 vx1 vy1 vz1 vx2 vy2 vz2

Just like the above, but for spherical coordinates. The (vx1,vy1,vz1) vector is the phi = 0 axis.

$$\text{new}(x, y, z) = \text{spherical coordinates}(\rho, \theta, \phi)$$

The grouping qualifier is:

lumped

Group all elements in the region on a single processor. If this qualifier is not given, the elements in the region are distributed across all processors.

together

Group all elements in the region as one “super” element and join decomposition together with other remaining parts. This qualifier works like “lumped” to keep all elements in the region on a single processor. It also assigns them on the same processor with their neighboring elements with load balanced. In general, this qualifier is recommended over “lumped”.

nproc n frstp

This region will be distributed to *n* processors which usually is a subset of *numproc* and starting from rank *frstp*. If *frstp* is not given, the code will select the *n* less cost processors from *numproc* automatically.

Examples:

rz 45

will generate domains rotated -45 degrees around the z axis.

C2R 0 0 0 0 0 1 1 0 0

will generate cylindrical shells of domains. They will have their axis along the vector (0,0,1), and will start at the vector (1,0,0) Note that the part will be cut at (1,0,0), so no domains will cross this boundary. If there is a natural boundary or opening in your part, the "theta = 0" vector should point through this opening. Note also that if the part is, say, a cylinder 100 units tall and 50 units in radius, after the C2R transformation the part will fit inside the box $x=[0,50]$, $y=[0, 2\text{PI}]$, $z=[0,100]$. In particular, the new y coordinates (theta) will be very small compared to the other coordinate directions. It is therefore likely that every decomposition domain will extend through the complete transformed y direction. This means that each domain will be a shell completely around the original cylinder. If you want to split the domains along radial lines, try this pair of transformations:

C2R 0 0 0 0 0 1 1 0 0

SY 5000

This will do the above C2R, but then scale y by 5000. This will result in the part appearing to be about 30,000 long in the y direction -- long enough that every decomposition domain will divide the part in this (transformed) y direction. The result will be decomposition domains that are radial "wedges" in the original part.

General combinations of transformations can be specified, and they are applied in order:

SX 5 SY .2 RZ 30

will scale x, then y, then rotate.

A more general decomposition might look like:

```
decomposition { rx 45 sz 10
  region { parts 1 2 3 4 5 and sphere 0 0 0 200 lumped }
  region { box 0 100 -1.e+8 1.e+8 0 500 or sphere 100 0 200 200 rx 20 }
}
```

This would take elements that have user ID 1, 2, 3, 4, or 5 for their part, AND that lie in the sphere of radius 200 centered at (0,0,0), and place them all on one processor.

Then, any remaining elements that lie in the given box OR the sphere of radius 200 centered at (100,0,200) would be rotated 20 degrees in x then decomposed across all processors. Finally, anything remaining would be rotated 45 degrees in x, scaled 10 in

APPENDIX O

z, and distributed to all processors. In general, region qualifiers can be combined using the logical operations **and**, **or**, and **not**. Grouping using parentheses is also supported.

EXECUTION OF MPP/LS-DYNA

MPP/LS-DYNA runs under a parallel environment which provided by the hardware vendor. The execution of the program therefore varies from machine to machine. On some platforms, command line parameters can be passed directly on the command line. For others, the use of the names file is required. The names file is supported on all systems.

The serial/SMP code supports the use of the SIGINT signal (usually Ctrl-C) to interrupt the execution and prompt for user input, generally referred to as “sense switches.” The MPP code also supports this capability. However, on many systems a shell script or front end program (generally “mpirun”) is required to start MPI applications. Pressing Ctrl-C on some systems will kill this process, and thus kill the running MPP-DYNA executable. As a workaround, when the MPP code begins execution it creates a file “bg_switch” in the current working directory. This file contains the following single line:

```
rsh <machine name> kill -INT <PID>
```

where < machine name > is the hostname of the machine on which the root MPP-DYNA process is running, and <PID> is its process id. (on HP systems, “rsh” is replaced by “remsh”). Thus, simply executing this file will send the appropriate signal.

Here is a simple table to show how to run the program on various platforms. Of course, scripts are often written to mask these differences.

| Platform | Execution Command |
|-----------|---|
| DEC Alpha | dmpirun -np n mpp-dyna |
| Fujitsu | jobexec -vp n -mem m mpp-dyna |
| Hitachi | mpirun -np n mpp-dyna |
| HP | mpp-dyna -np n |
| IBM | #!/bin./ksh export MP_PROC=n export MP_LABELIO=no export MP_EUILIB=us export MPI_EUIDEVICE=css0 poe mpp-dyna |
| NEC | mpirun -np n mpp-dyna |
| SGI | mpirun -np n mpp-dyna |
| Sun | tmrn -np n mpp-dyna |

Where n is the number of processors, *mpp-dyna* is the name of the MPP/LS-DYNA executable, and m is the MB of real memory.

APPENDIX P: Implicit Solver

INTRODUCTION

The terms implicit and explicit refer to time integration algorithms. In the explicit approach, internal and external forces are summed at each node point, and a nodal acceleration is computed by dividing by nodal mass. The solution is advanced by integrating this acceleration in time. The maximum time step size is limited by the Courant condition, producing an algorithm which typically requires many relatively inexpensive time steps.

While explicit analysis is well suited to dynamic simulations such as impact and crash, it can become prohibitively expensive to conduct long duration or static analyses. Static problems such as sheet metal springback after forming are one application area for implicit methods. In the implicit method, a global stiffness matrix is computed, inverted, and applied to the nodal out-of-balance force to obtain a displacement increment. The advantage of this approach is that time step size may be selected by the user. The disadvantage is the large numerical effort required to form, store, and factorize the stiffness matrix. Implicit simulations therefore typically involve a relatively small number of expensive time steps.

In a dynamic implicit simulation these steps are termed *time steps*, and in a static simulation they are *load steps*. Multiple steps are used to divide the nonlinear behavior into manageable pieces, to obtain results at intermediate stages during the simulation, or perhaps to resolve a particular frequency of motion in dynamic simulations. In each step, an equilibrium geometry is sought which balances dynamic, internal and external forces in the model. The *nonlinear equation solver* performs an iterative search using one of several Newton based methods. *Convergence* of this iterative process is obtained when norms of displacement and/or energy fall below user-prescribed tolerances. Within each implicit iteration there is a *line search* performed for enhancing robustness of the procedure.

The implicit analysis capability was first released in Version 950. Initially targeted at metal forming springback simulation, this new capability allowed static stress analysis. Version 970 added many additional implicit features, including new element formulations for linear and modal analysis. A milestone in implicit was the advent of Version 971 in which implicit analysis was carried over to MPP and thus allowed much larger problems to be solved, and from there it has evolved extensively to presently contend well among competitive softwares. Still, it can be a gruesome task to set up an implicit input problem that runs all the way to completion with acceptable results, especially when contacts are involved. The purpose of this text is to explain keywords of interest and suggest values of important parameters in order to give users tools for developing own solution strategies to these kinds of problems.

APPENDIX P

A prerequisite for running implicit is to use a double precision version of LS-DYNA, and a machine with a significant amount of memory. A theoretical overview of implicit can be found in the LS-DYNA Theory Manual [implicittheorychapter](#).

NONLINEAR IMPLICIT ANALYSIS

Activating Implicit Analysis

The keyword `*CONTROL_IMPLICIT_GENERAL` is used to activate the implicit method, and in principle it is sufficient to set

```
IMFLAG = 1
DT0 = some reasonable initial time step.
```

The initial time step should be chosen small enough to resolve the frequency spectrum of interest and/or provide decent convergence properties, but large enough to benefit from an implicit analysis. With no other implicit options, this converts an explicit input deck to a static implicit input deck with a constant time step throughout the simulation and the problem will terminate upon convergence failure. Time stepping strategies to prevent this are discussed [Time Stepping Strategies](#)

Singularities and Eigenvalue Analysis

The first concern in implicit analysis is to prevent singularities in the stiffness matrix, otherwise the chance of succeeding is close to none. The major source to a singular stiffness matrix is the presence of rigid body modes in a static problem, and these can be revealed in an eigenvalue analysis. This is done by using `*CONTROL_IMPLICIT_EIGENVALUE` and putting

```
NEIG = number of modes to extract.
```

Run an eigenvalue analysis and extract (if practically possible) enough modes to see all the rigid body modes just to get an impression of the properties of the model. The frequencies are in the output text file "eigout" and the mode shapes can be animated in the binary output file "d3eigv" using LS-PrePost. Some rigid body modes may come as a surprise and should be constrained, a typical example of this are beams that are free to rotate around its own axis. Other rigid body modes are a consequence of the nature of the problem and cannot be constrained without destroying the connection to reality, an example of this could be components that are to be constrained with contacts but are initially free to move. There are several strategies to deal with these latter rigid body modes, some are discussed in the context of contacts but here dynamics is used.

Dynamics and Intermittent Eigenvalue Analysis

Dynamics alleviates singular rigid body modes and is activated on `*CONTROL_IMPLICIT_DYNAMICS` by putting

IMASS = 1 or a negative number.

If the purpose is to solve a dynamic problem in the first place, then just use IMASS = 1 and don't bother about the other parameters, otherwise some other strategy is necessary. The idea is to get off to a start using dynamic analysis, and as the simulation gets to a point where rigid modes have been constrained by contacts, dynamics is turned off. The simplest way of doing this is to put

TDYBIR = 0

TDYDTH = time when contacts have been established and rigid body modes are constrained

TDYBUR = time after TDYDTH for fading out dynamics between TDYDTH and TDYBUR.

If the dynamic results are of no interest but just a way to proceed to the static solution, then it is recommended to use numerical damping to prevent unnecessary oscillations, i.e., put

GAMMA = 0.6

BETA = 0.38.

This should be enough to start up most problems of interest. A restriction with this is that when dynamics has been turned off it cannot be turned on again. If this is necessary for some reason, then a negative number of IMASS should be used to control dynamics through a load curve.

If it is hard to deduce how to choose the time when to turn off dynamics, the use of intermittent eigenvalues may be of great help. By putting

NEIG = a negative number

on *CONTROL_IMPLICIT_EIGENVALUE the user may extract eigenvalues at given time points during a nonlinear simulation and deduce from that if all rigid body modes have been eliminated.

The Geometric Stiffness Contribution

Stiffness singularities may also occur during simulation due to a complex global phenomenon involving the stress state and geometry. For instance could slender components with compressive stresses give rise to zero eigenvalues, commonly known as buckling. The mathematical explanation to these kinds of singularities is that the material and geometric stiffness contributions cancel out, and for this reason the geometric contribution to the stiffness matrix is in LS-DYNA optional. It is activated by putting

APPENDIX P

IGS = 1

on *CONTROL_IMPLICIT_GENERAL. Most often singularities due to this contribution have a negative effect on convergence although it sometimes helps. It is recommended to leave this as default and turn it on if other strategies fail. A controlled way of getting past singular points of this type is to use so called arc length methods for which the geometric stiffness should be turned on, this way of dealing with the problem is discussed in the Theory Manual [arclengthchapter](#).

BFGS or Full Newton

The nonlinear solver parameters are set on *CONTROL_IMPLICIT_SOLUTION where the solver type is specified as

NSOLVR = nonlinear or linear implicit analysis option

By default, a nonlinear BFGS solution strategy is used where the stiffness matrix is reformed every 11th iteration and a maximum of 15 reformations is allowed (for a linear solution set NSOLVR = 1). These parameters are set by

ILIMIT = iterations between reforming stiffness matrix

MAXREF = maximum number of stiffness reformations

on *CONTROL_IMPLICIT_SOLUTION. Reforming the stiffness matrix is computationally expensive but stabilizes the solution procedure, and the best strategy in this context is very much problem dependent. The recommendation is to start with the default strategy and if necessary change them. For hard problems decrease ILIMIT and for problems that converge well increase ILIMIT. For really bad problems switch to full Newton (the safe bet) by for instance putting

ILIMIT = 1

MAXREF = 30.

Keep the maximum number of reformations reasonably low or otherwise it may take an unnecessary amount of time just to reach convergence failure.

Convergence

Tolerances

Convergence is based on changes in displacements, energies and optionally residual forces, and the tolerance levels are set by

DCTOL = Relative displacement tolerance

DMTOL = Maximum displacement tolerance

ECTOL = Relative energy tolerance

EMTOL = Maximum energy tolerance

RCTOL = Relative residual tolerance RMTOL = Maximum residual tolerance
 ABSTOL = Absolute tolerance

on *CONTROL_IMPLICIT_SOLUTION. The tolerances on the left are based on Euclidian norms of the involved vectors, whereas the ones on the right are based on maximum norms. The maximum norm tolerances are optional and should be activated if increased accuracy is desired at the price of more implicit iterations. To keep things simple, the discussion that follows pertains only to the Euclidian norm tolerances. By default, the progress of the equilibrium search is not shown to the screen but can be activated using

NLPRINT = nonlinear output diagnostics

input parameter. The box below shows a typical iteration sequence, where the norms of displacement and energy are displayed. When these norms are reduced below user prescribed tolerances (default 0.001 and 0.01, respectively), the iteration process is said to have *converged*, and the solution proceeds to the next time step. The message files, messag in SMP and mesXXXX in MPP, typically contain a whole lot more information that will be dealt with further in [Output](#) and [Stretching for Convergence](#).

```

BEGIN static time step      3
=====
                time =  1.50000E-01
      current step size =  5.00000E-02
Iteration:   1      *|du|/|u| =  3.4483847E-01      *Ei/E0 =  1.0000000E+00
Iteration:   2      *|du|/|u| =  1.7706435E-01      *Ei/E0 =  2.9395439E-01
Iteration:   3      *|du|/|u| =  1.6631174E-03      *Ei/E0 =  3.7030904E-02
Iteration:   4      *|du|/|u| =  9.7088516E-05      *Ei/E0 =  9.6749731E-08
  
```

Premature Convergence

The last of these parameters (ABSTOL) overrides the other three (DCTOL, ECTOL, RCTOL) in the sense that if the residual force is small enough, convergence is detected regardless if the other three criteria are fulfilled or not. It has been seen that this sometimes give rise to so called *premature convergence*, converged states are not *really* converged in the sense that the residual norm is small enough. This gives bad results and it is usually recommended to tighten this tolerance to 10^{-20} to prevent this. On the other hand, if the problem is very hard this may prevent convergence to the extent that going back to the default is more or less necessary. It is difficult to give a general recommendation that holds for every problem.

As for the other three parameters, the one that usually comes into practice is the displacement criterion DCTOL. The energy criterion ECTOL is often easy to fulfill and the residual criterion is disabled by default and there may be no reason to activate this (that is unless a completely [Using Residual Tolerance](#) is used, or if [Stretching for Convergence](#) arise). Using the default values on all three is usually good enough to give acceptable results in decent time. For problems with poor convergence, the question of tightening or relaxing these parameters (that is the displacement convergence criterion)

APPENDIX P

is up for debate. It is tempting to believe that relaxing the constraints will give better convergence which may or may not be true. Sloppy convergence criteria may once again result in premature convergence, and this will have a negative effect on the subsequent steps. The general recommendation would have to be to leave these unchanged, and be aware that relaxing them may not result in getting further in the implicit simulation.

Using Residual Tolerance

A novel strategy that seems to make sense and works well for some problems is to only use tolerances on residual forces RCTOL. This relies much on that the degree of nonlinearity of the simulation model is moderate, but it could be well worth trying. The first thing to do would be to put DCTOL and ECTOL to large numbers to disable them and put RCTOL to a relatively small number, start with 0.01 and see how that works out. This must be complemented with an absolute tolerance on the residual forces to get past the initial stages where the residual forces are small enough to not fulfill the relative tolerance. This is done by putting ABSTOL to a negative number, which is a different absolute criterion compared to putting it to a positive number. Now, this number is very problem dependent as this says that convergence is attained as soon as the Euclidian norm of the residual force vector is smaller than the absolute value of ABSTOL. It goes without saying that this require running the problem for a few steps to monitor the residual norm in the message files as described below, this should give an indication on how to determine the ABSTOL value.

Convergence Norms

The degrees of freedom encountered in an LS-DYNA simulation are either *translational* or *rotational*, where the latter comes from the presence of beams and shells. Historically, convergence check is on norms of the translational degrees of freedom only, which is unsettling from the fact that rotational residual forces (moments) are equally important in an implicit simulation. It is therefore recommended to use

NLNORM = choice of convergence norms

on *CONTROL_IMPLICIT_SOLUTION to change this default (which is = 2). While NLNORM = 3 will incorporate residual degrees of freedom separately and is a more satisfying approach, the recommended option is to use NLNORM = 4 or NLNORM a negative number. NLNORM = 4 will treat the entire force and displacement vector, respectively, as one complete mathematical vector and the convergence norms and scalar products used for checks are simply the Euclidian norms of these vectors. To make the displacement and residual norms unit consistent a scale factor l , corresponding to a characteristic element size in the model, is introduced and accounted for when computing the norms. This means for instance that displacements are summed to l length unit times angular increments, and moments are summed to l length unit times forces. For NLNORM = 4 the scale factor is echoed to the output files and screen, and if the internally calculated value is inappropriate for some reason, it may be convenient to use NLNORM = -(length scale) to supersede this scale factor.

Time Stepping Strategies

By default, LS-DYNA will terminate when a step fails to converge. This is unfortunate since it may just be that the step is too large to achieve convergence and taking smaller steps would solve this problem. Instead of starting all over with a smaller step size, set

IAUTO = 1 to activate automatic time stepping

on *CONTROL_IMPLICIT_AUTO. When the problem fails to converge LS-DYNA will with this option go back to the previously converged state and retry with a smaller step size. If the problem converges well, the step size is increased for subsequent steps. This process of backing up and retrying difficult steps lends much persistence to the analysis, and is often the only procedure for solving highly nonlinear problems short of adjusting the step size manually and the recommendation is to always turn automatic time stepping on.

Another parameter worth mentioning in this context is

DTMAX = Max time step allowed, or a negative number

on the same card. This is the maximum step size possible and should be chosen so as to not lose necessary information in the results, i.e., be sure to resolve frequencies, contacts and nonlinear material response to a satisfactory degree. A negative value of this parameter will give the maximum step size as a function of the simulation time and also allows for hitting key points that are of interest. The user may for instance look for the peak stress for a certain external load and hitting the point in time when this happens is crucial. It also allows for taking smaller steps during critical stages in the simulation without wasting resources away from these stages.

Line Search

A good line search strategy is crucial in solving nonlinear implicit problems, without it only simple problems would be solvable. There are a few line search options available and these are activated by

LSMTD = Line search method

on *CONTROL_IMPLICIT_SOLUTION. The default method is based on minimizing a potential energy along the search direction and at the same time keeping track of the residual force magnitude. It also detects when a BFGS step results in negative initial energy and the stiffness matrix is reformed for robustness (this can only happen when the stiffness matrix has negative eigenvalues), and even suppresses the occurrence of negative volumes. Line search type 2 is based on residual forces and is more robust than the others, the drawback is that it typically results in too small steps and is not practically useful. Line search type 3 is very similar to type 4, but is not tracking the residual force or avoids negative volumes to the same extent, and in sum there is no

APPENDIX P

practical reason for choosing methods 1 through 3. Worth mentioning is however line search type 5 which combines the energy and residual method in a stricter sense. That is, it minimizes the potential energy just like type 4 but it only allows the residual norm to double at each implicit iteration. This has shown to be robust but on the other hand slow in convergence and is to be used for problems that have difficulties to converge with the default line search strategy. This has had a huge impact on the treatment of rubber models for instance. An interesting combination is to use line search method 5 together with the strategy of converging based on [Using Residual Tolerance](#).

Finally, the line search tolerance

LSTOL = Line search tolerance

on *CONTROL_IMPLICIT_SOLUTION is fine as it is, don't change it.

Output

As previously mentioned, the output to the message file is more extensive than that to the screen/stdout. To novice or average implicit users this information may be more than can be digested at first and this section may be [LINEAR EQUATION SOLVER](#), but with experience the output can become really useful when running into convergence issues. For this discussion it is important to distinguish between different *types* of iterations, and we use the term *time/load step* to mean the actual advance in simulation time, *implicit iteration* to indicate points in the iterative solution procedure where a new search direction is obtained (corresponding to either Newton or BFGS) and *line search iteration* to indicate the search for an optimal step size along a given search direction. We begin by showing a typical iteration output for when NLPRINT = 3 following by a bulletin list explaining the content.

```

Referring to the superscripts at the beginning of the lines in the excerpt above, and taking them in order of appearance, we have at

1. Beginning a *dynamic* implicit time/load step, the goal is to get to a given time point (in this case 2.5849E-01 using a step size of 1.58489E-01). Implicit time/load steps are either *dynamic*, *static* or *semidnmc*, where the last one indicates a transition phase between dynamics and statics.
2. A *Newton* implicit iteration is performed, meaning that a full reformation of the stiffness matrix has just been made. Other implicit iterations can be either a *linear* if at the first iteration of a time/load step, or *BFGS* if the implicit iteration corresponds to a quasi-Newton step.
3. Initial norms are displayed at the beginning of each implicit iteration, these numbers are used as reference for the line search algorithm when checking line search convergence.
4. Detailed initial norms are displayed, separating out translational/rotational as well as nodal/rigid body Euclidian/max norms. The node number and rigid body attaining the global maximum norms are displayed and can be used to spot critical points in the model, in this particular case node 440984 and part 4000024 would be the likely candidates to trouble.
5. A full step along the search direction is taken, as a candidate for the next implicit iteration.
6. Norms for the full step is displayed, the line search algorithm compares these with the ones from 3 to deduce if line search convergence criterion is fulfilled.
7. Line search is in this case needed, and information for further iterates along the search direction is displayed in analogy to previous line search iterates. If no line search had been needed, the string *Line search is skipped* would have been displayed.
8. The way line search is performed, each line search iteration narrows in on the optimal step and the bounds within which the optimal step is sought is continuously displayed. The size of this interval becomes smaller and smaller with increasing number of line search iterations, but convergence should preferably be attained before it tends to zero.
9. Line search converged here in 2 iterations; as a rule of thumb the number of iterations for line search should be about 10 or less. For critical steps one might

accept 20 iterations but that should be among the exceptions. If the string *Line search did not converge* is displayed, that is an indication of something being terribly wrong.

10. After each implicit iteration, *Max relative step* indicates how large steps have been taken during line search so far. It also indicates how well prescribed motion is approximated where a value of 1 is perfect. For values below 1 and in the presence of non-zero prescribed motion, convergence will not be accepted even though all norms are within prescribed tolerances. This will instead issue the warning *Convergence prevented due to unfulfilled boundary conditions* and iterations continue.
11. Diagnostics for iteration 5 is displayed, similar numbers as shown during line search but in another format. Furthermore, the initial norms here refer to the initial norms from the beginning of the implicit time/load step and not from the beginning of the implicit iteration. This table can be used to deduce how close the implicit time/load step is at converging. The single important number for comfortably assessing the accuracy of an implicit iterate is the residual norm, currently displayed as 1.258E+00 (bold-faced in the table), since this should be small for good results.

At equilibrium, the output ends with a summary on how convergence was achieved. It may look like

```

Convergence detected as a combination of
  1. Ratio of euclidian displacement
      Value = 2.3417E-03 vs Tolerance = 2.5000E-3
  2. Ratio of euclidian energy
      Value = 3.2269E-08 vs Tolerance = 1.0000E-2
    
```

which tells us that the ratio of displacement was below $DCTOL = 2.5E-3$ and the ratio of energy was below $ECTOL = 1E-2$. If other criteria are satisfied, these will be listed too.

So, with $NLPRINT = 3$ information from every force evaluation is given, including type of step taken, the line search step size, the potential energy value used in line search and the magnitude of the residual force. A point is made here, already [Premature Convergence](#) and will be repeated, and it is the following. The nonlinear implicit solver is solving for zero residual force, so basically the number observed for the magnitude of the residual force should be small upon convergence (bold-faced in the table). If it is not, then the convergence is premature and the results may not be correct and subsequent steps are in danger. What “small” means in this context is hard to say since this depends on units as well as loads and geometry of the problem, but a good sign is that the residual force does not grow by more than the external loads in the problem do. Another thing to observe is how the [Line Search](#) is doing, if the line search starts needing many iterations and very large variations in the residual force along the search direction is observed, then it is likely that something in the model is causing this behavior. A safe bet is that contact states are changed along the line search direction

APPENDIX P

causing discontinuities in the residual force and indicates that some remodeling has to be done.

We will come back to this section when discussion [Taking Advantage of ASCII Information](#) and strategies to prevent them.

LINEAR EQUATION SOLVER

General

Within each equilibrium iteration, a linear system of equations of the form $K\Delta u = R$ must be solved. To do this, the stiffness matrix K is factorized and applied to the out-of-balance load or residual R , yielding a displacement increment Δu . Storing and solving this linear system represents a large portion of the memory and CPU costs of an implicit analysis. LS-DYNA uses a multi-frontal sparse direct solver and nested dissection, and for a problem with N number of nodes, the number of operations and memory storage is asymptotically proportional to $N^{3/2}$ and $N\log N$, respectively. This should give a ballpark indication on the growth when increasing the size of a given model. It must be stressed however that it is *a priori* difficult to predict the actual value of these numbers as they are highly dependent on the problem solved, in particular on the nodal connectivity through elements and contacts. In the end we are left at qualitative guessing how to set memory flags or determining model size in order to push the limits for a given computer architecture.

We here focus on the memory, and the purpose is twofold. First it is a documentation of the memory diagnostics that is written to the output message files (messag in SMP and mesXXXX in MPP) of LS-DYNA for the linear solvers. The level of information is regulated by the

LPRINT = Linear solver diagnostics level

input parameter on *CONTROL_IMPLICIT_SOLVER, and this text will cover LPRINT = 2 as the information for higher values is of no particular interest to others than developers. Second it should help understanding the interrelationship between the size of a model and the memory required to obtain a solution. We emphasize however that different classes of problems most likely require different guidelines (shell and solid structures typically result in different matrix topologies for instance) and to this end the user is left at earning this experience on his own.

Memory

The memory is specified and reported in terms of *words*, where 1 word is equivalent to 4 bytes in single precision and 8 bytes in double precision arithmetic. To simplify things, a word can in this context be seen as the equivalent of a real number or an integer. For implicit calculations the executable used is typically double precision, so to convert from words to bytes one needs to multiply by 8.

In starting a simulation the user typically specifies the *static* memory, for instance in SMP

```
ls-dyna i = in.k memory = 200m
```

meaning that LS-DYNA tries to allocate 200 Mwords for storing most of the data. In MPP, the physical memory is distributed among processes and this option applies to each individual process. In MPP there is also an option to add a second memory flag, for instance

```
mpp-dyna i = in.k memory = 1000m memory2 = 200m
```

and this means that 200 Mwords are allocated for each process while 1000 Mwords is allocated on the first process to handle everything up to the point when the model data has been distributed among all the involved processes. The memory size may also be specified on *KEYWORD. *For implicit it is recommended to avoid memory2 in order to keep the memory balance between processors.*

When a certain feature requires a slot in the memory, this is reported in the output text files, for instance as

```
contracting memory to    2306940 implicit friction
expanding  memory to    2306955 joints
```

In the example above, the memory pointer after having allocated for implicit friction is at 2306940 and joints reserves 15 words and increment the memory pointer accordingly. So the memory used up to this point is roughly 2.3 Mwords for this particular process. At the end of the initialization a memory report is written and can look like

```
S t o r a g e   a l l o c a t i o n
Memory required to begin solution      :    2680153
Linear Alg dynamically allocated memory:    880685
Additional dynamically allocated memory:   1553130
Total:                                5113968
```

The total amount of memory used up to this point is roughly 5.1 Mwords, which is partitioned in the static memory specified and *dynamic* memory that is allocated on the fly so to speak, typically if a certain amount of memory needed cannot be estimated in due time to adequately include it in the static chunk of memory. Whenever a memory violation occurs, for instance when trying to allocate more memory than physically available or if more memory needs to be specified, LS-DYNA terminates with appropriate error information. The static memory for the linear solver is allocated thereafter, which is the topic for the next section.

Linear Solver Memory Consumption

For LPRINT = 2, some memory information is given in the output files, and this is here presented in order of execution, thus as they appear in the files. We repeat that this is

APPENDIX P

the information obtained in the message files and is thus referring to the memory consumption for this particular process if MPP is considered. For the sake of completeness we also cover the diagnostics related to the CPU time for the involved stages in the linear solution.

First the memory required for handling constraints is reserved and is reported as

```
expanding memory to 2893375 implicit lsolvr allocation 1
```

After this memory is reserved for symbolic factorization, which is performed prior to the actual solve to predict the storage requirement for the factorized system matrix. This allocation is reported as

```
expanding memory to 7639758 implicit matrix storage
```

Also, some memory is reserved for the sparse matrix, including index pointers to non-zero elements, and is reported as

```
expanding memory to 15077248 linear eqn. solver allocation 2d
```

Here the last information (2d) is referring to the solver used and may change depending on user options.

Before the symbolic factorization takes place, current information on the system matrix and workspace reserved for implicit is reported

```
local number of rows      =          68490
local size of matrix      =         2338945
local len of workspace    =         15077248
ptr to start of wrkspc    =          2893375
```

The first number refers to the number of independent degrees of freedom in the model, i.e., the number of rows in the system matrix, and the second to the number of nonzero entries before factorization takes place, i.e., after assembly. The third row of information is somewhat misleading as this is actually the total amount of memory reserved and not the size of the workspace itself. The workspace here means the memory reserved for the linear solution, and its size is obtained by subtracting the pointer to start of workspace and the local length of workspace.

The symbolic factorization is now performed and information on the CPU time for doing this together with the estimated size of the factorized matrix is reported

```
CPU: symbolic factor      =          0.200
WCT: symbolic factor      =          0.203
storage currently in use  =         1038915
storage needed           =         12913838
factor speedup           =         1.9197E+00
solve speedup           =         1.9378E+00
est. factor non zeroes   =         5.1432E+07
```

```
est. factor operations = 1.2099E+11
est. total factor nz. = 9.9666E+07
est. max. factor op. = 1.2099E+11
est. total factor op. = 2.3293E+11
est. max. factor nz. = 5.1432E+07
```

The first two rows reports the CPU and wall clock time for doing the symbolic factorization in terms of seconds. The next two are storage requirements for the symbolic factorization, of which the latter is the memory reserved for this. After this we have estimations of the speedup in the factorization and subsequent solve of the linear system of equations, this is a report from an MPP run on 2 processors. The last lines refer to the estimated requirement for storing and factorizing the system matrix, and distinguish between the local, total and maximum number of each of these two entries. This allows for determining the memory scaling in the case of an MPP run.

Now LS-DYNA is in the position of reserving space for the factorization of the system matrix, and a report on the storage needed for this is given.

```
symbolic storage      1 =          1038915
in-core numeric storg 1 =          62762269
out-of-core num. storg 1 =          13168676
symbolic storg 1 =              1.04 Mw
in-core numericl storg 1 =          69.06 Mw
out-of-core num. storg 1 =          14.51 Mw
```

Here basically the same information is repeated, except for a slight increment in order to account for potential penalty when doing the actual factorization. The first is again the memory reserved for the symbolic factorization and the other two are the memory required to perform an in-core and out-of-core factorization, respectively. If the memory available is not sufficient for doing an in-core factorization, LS-DYNA warns about this and attempts to do an out-of-core factorization, which means that the hard disk is used to store information during factorization. If this warning appears it is recommended to restart the simulation and using more memory since out-of-core significantly (writing to disk is more expensive than accessing memory) adds to the wall clock time for solving the problem. If the memory for doing an out-of-core factorization is insufficient, LS-DYNA will terminate with an error message. Otherwise, memory is reserved and reported

```
expanding memory to 77737167 linear eqn. solver numerical phase 1
```

meaning that the total amount of memory reserved at this point is roughly 78 Mwords. At this point a redistribution of the system matrix is performed and a short report is given on this

```
symbolic storage      2 =          1038915
in-core numeric storg 2 =          68238926
out-of-core num. storg 2 =          11553502
```

APPENDIX P

Now the actual factorization takes place and a report from this is given where the information of interest is

```
CPU: factorization      =          59.025
WCT: factorization      =          50.151
act. factor nonzeros    =       5.1236E+07
act. factor operations   =       1.2092E+11
act. max. factor nz.    =       5.1236E+07
act. max. factor op.    =       1.2092E+11
act. total factor nz.   =       9.9666E+07
act. total factor op.   =       2.3293E+11
```

which basically is the same information as from the symbolic factorization except that now it is the actual instead of the estimated values that is reported.

Finally, the forward and backward substitutions are allocated for and performed. The information given is

```
symbolic storage        3 =          1038915
in-core numeric storg   3 =          68299122
out-of-core num. storg 3 =          16476693
CPU: numeric solve      =           0.191
WCT: numeric solve      =           0.194
```

Concluding, the wall clock time for solving the system of linear equations is reported

```
WCT: total imfslv_mf2   =          75.079
```

ELEMENTS AND MATERIALS

Implicit Accuracy

Implicit and explicit analysis differ in many respects, an important one is that the deformation during a single step is much larger in implicit than a typical one in explicit. In the context of elements and materials, the demand for stronger objectivity and higher accuracy in implicit is obvious. The notion of implicit executing the same algorithms as a corresponding explicit analysis is whence not adopted in general. This can optionally be further extended, using

IACC = 1 to increase implicit accuracy

on *CONTROL_ACCURACY will make selected elements strongly objective and enhance the accuracy for selected materials. For instance will finite rotations be represented exactly and fully iterative plasticity adopted. In addition, the flag applies to tied contacts as will be elaborated on below. Currently the following elements are supported for this option

Solid elements -2,-1,1,2
Shell elements 4,-16,16,23,24
Beam elements 1,2,9

and materials 24 and 123 use fully iterative plasticity.

CONTACTS

Contacts are probably among the hardest features to treat in a nonlinear implicit simulation. They are divided into the categories *tied* (bilateral) and *sliding* (unilateral) contact, and the characteristics of the two are quite different. Tied contacts are most often applied as constraints, only sometimes using a penalty formulation, and are fairly easy to deal with as they are only moderately nonlinear. In contrast, sliding contacts are exclusively implemented as penalty contacts and hard to deal with because of the unilateral condition. While the number of contacts, see *CONTACT, in LS-DYNA is abundant, we will here only present the few contacts that make most sense to use in implicit.

Tied Contacts

Tied contacts in implicit analysis should be accompanied with the [Implicit Accuracy](#) option, as this essentially reduces the number of relevant contacts to use to only six. These six contacts are

- *CONTACT_TIED_NODES_TO_SURFACE
- *CONTACT_TIED_NODES_TO_SURFACE_CONSTRAINED_OFFSET
- *CONTACT_TIED_NODES_TO_SURFACE_OFFSET
- *CONTACT_TIED_SHELL_EDGE_TO_SURFACE
- *CONTACT_TIED_SHELL_EDGE_TO_SURFACE_CONSTRAINED_OFFSET
- *CONTACT_TIED_SHELL_EDGE_TO_SURFACE_BEAM_OFFSET

The first and fourth of these project the nodes on the slave side to the master surface, while the rest are offset contacts for which nodes will remain in place. The fourth, fifth and sixth constrain rotations while the others do not. The third and sixth are penalty based, while the others are constraint based. In sum, these six contacts cover most reasonable scenarios.

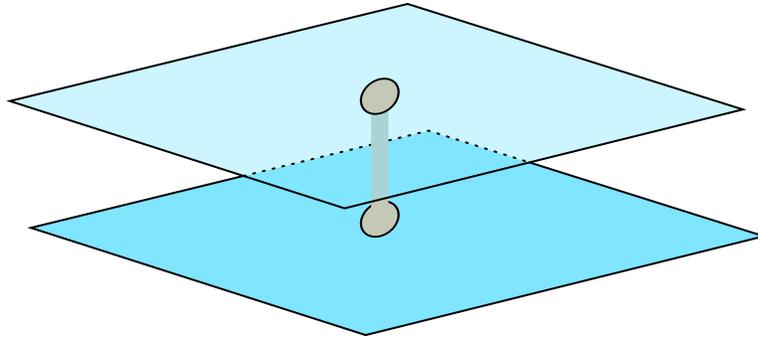

Figure 60-1. Modeling spotwelds by connecting a beam element to two shell elements.

The implicit accuracy option will in this context make these six tied contact [strongly objective](#), and built-in intelligence will detect whether nodes contain rotations to constrain or not. A nice feature with the latter is that torsion is automatically applied with physical consistency, so it is for instance no problem to use single beams to model spotwelds between solid elements, and when using the same connection technique between shells the beam axial rotational degrees of freedom will be constrained to the translational degrees of the shells and thus avoiding the relatively weak (and non-physical) drilling degree of freedom. This situation is depicted in [Figure 60-1](#).

The choice of contact depends on the situation, but from a conceptual point of view it should be ok to use `*CONTACT_TIED_SHELL_EDGE_TO_SURFACE_CONSTRAINED_OFFSET` for most cases. The only problem then would be if complicated geometry results in termination due to overconstraining, for which a switch to the corresponding penalty version `*CONTACT_TIED_SHELL_EDGE_TO_SURFACE_BEAM_OFFSET` is motivated. See [remarks](#) in the LS-DYNA keyword manual for more information.

Sliding Contact

The choice of contact in this section is the [Mortar contact](#) as this seems to be best implicit contact algorithm when considering a combination of speed, accuracy and robustness. The Mortar contact features smoothness and continuity that is highly appreciated in implicit analysis, but is on the other hand expensive enough to not be recommended for explicit analysis. Many other contact algorithms are supported for implicit analysis and execute faster than the Mortar contact, but this is often seen when the infamous IGAP flag is set to default. This flag manipulates the stiffness matrix to the extent that accuracy may be deteriorated, and if used the results should be thoroughly checked. For Mortar contact IGAP has a different meaning as will be described [IGAP](#). See [remarks](#) in the LS-DYNA keyword manual for more information.

Basics

The Mortar contact is activated by typically appending the suffix MORTAR to the automatic single surface, automatic surface to surface or forming surface to surface keywords. It can also be run as tied and tiebreak contacts. All Mortar contacts are

segment to segment and penalty based and the tied and tiebreak contacts are always offset, i.e., the tie occurs on the outer surfaces of shells and not on the mid surfaces. For automatic contacts, edge contact with flat edges is always active. At this point, it possesses features that are of particular interest to implicit and that are not available for other contacts. It is supported in both SMP and MPP but the option MPP does not apply, and the SMP ignore flag applies. The SOFT flag does not apply, to summarize it is a contact algorithm especially intended for implicit analysis.

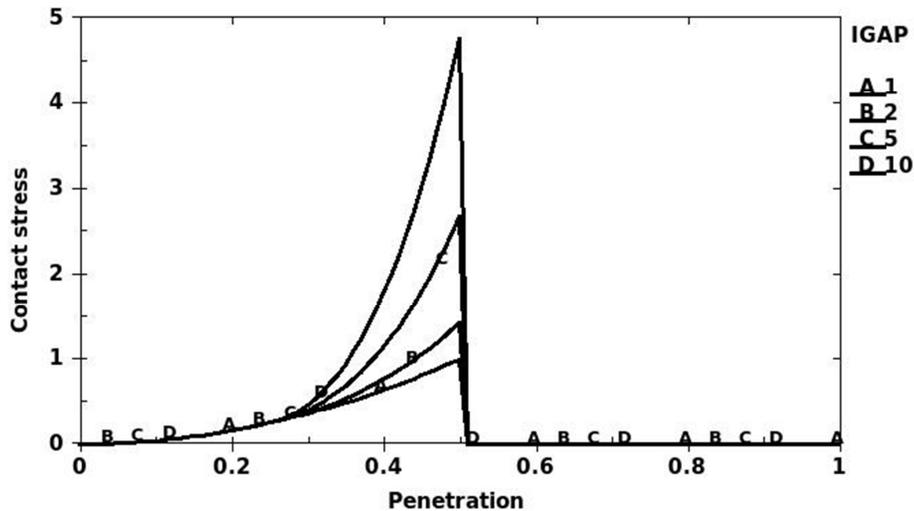

Recommendations

For the forming contact the rigid tools must be meshed so that the normals are directed towards the blank, and contacts from above and below must be separated into two or more interfaces because contact can only occur from one side of the blank for a given contact interface. For the forming contact, rigid shells on the master side have no contact thickness. This is not the case for automatic contacts, here there are no restrictions on the mesh and even rigid shells have contact thickness. For all Mortar contacts, part or part set based slave and master sides are recommended although not mandatory. If the two sides in the contact interface have different stiffness, use the weak part as slave in order to get the best possible implicit convergence behavior. This is automatically taken care of in a single surface contact.

Characteristics

The contact pressure in the Mortar contact is a parabolic function of the penetration in combination with a cubic stiffening phase. In short, the contact stiffness depends on the slave side material and a characteristic length of the slave side segment. The characteristic length is for shells the shell thickness and for solids it is a median of the edges in the slave side of the contact interface, and the maximum penetration allowed is given as 95% of the average characteristic lengths on master and slave sides. For solids the definition of the characteristic length may have the consequence that the stiffness becomes unnecessarily high if some elements are much smaller than most, and stiffness adjustments may be necessary. Furthermore, the characteristic length also determines the maximum penetration as well as the search radius for finding contact pairs, for this reason the characteristic length can optionally be increased by assigning it on PENMAX on optional card B. In most cases it is expected that default value (=0.0) for this parameter will suffice.

APPENDIX P

IGAP

The contact stiffness is parabolic with respect to penetration up to a penetration depth corresponding to half of the maximum penetration. For $IGAP = 1$ it will remain parabolic for even larger penetrations but the user may increase $IGAP$ which means that the contact will stiffen for larger penetrations, in fact it will become cubic according to the picture above. The purpose of increasing $IGAP$ could be to prevent the penetration from becoming larger than the maximum allowed penetration, because if convergence is attained with penetrations larger than this value this contact will be released in subsequent steps and the simulation is likely destroyed. Penetrations of this depth are likely to cause discontinuities along line searches and other discouraging phenomena. The user may of course scale the stiffness by increasing SFS but this also scales the stiffness for small penetrations and probably has a negative effect on convergence.

Output for debugging

Just as for implicit in general, [Output](#) is always a good thing to have when convergence starts deteriorating and considering the release of contact in the previous section, it would be interesting to know if penetrations are large enough for this to be a potential danger. First, initial penetrations are always reported in the message file(s), including the maximum penetration and how initial penetrations are to be handled. The latter depends on the value of the `IGNORE` flag and this is dealt with [Initial Penetrations](#). In addition, by putting

```
MINFO = 1
```

on `*CONTROL_OUTPUT`, LS-DYNA will report the absolute maximum penetration as well as the maximum penetration in percentage after each equilibrium. If the relative maximum penetration reaches above 99% a warning message is printed as this particular contact is close to being released. The output is exemplified in the following.

```

Contact sliding interface          1
Number of contact pairs          527

Maximum penetration is 0.2447797E+00 between
elements      306774 and      306672

Maximum relative penetration is 0.2266694E+02 % between
elements      306742 and      306733

Contact sliding interface          2
Number of contact pairs          16209

Maximum penetration is 0.5027643E+00 between
elements      219492 and      94935

Maximum relative penetration is 1.0366694E+02 % between
elements      219492 and      94935
*** Warning Penetration is close to maximum before release

```

This percentage value should ideally be kept below some 90 % to have some sort of comfort margin. There are three ways to reduce maximum relative penetrations, and these are (i) to increase **IGAP**, (ii) to increase **PENMAX** for solids or (iii) to increase **SFS**.

Initial Penetrations

As mentioned above, initial penetrations are always reported in the message file(s), including the maximum penetration and how initial penetrations are to be handled. The **IGNORE** flag governs the latter and the options are

- IGNORE < 0 Same functionality as the corresponding absolute value, but contact between segments belonging to the same part is ignored completely
- IGNORE = 0 Initial penetrations will give rise to initial contact stresses, i.e., the slave contact surface is not modified, *this is not available for Mortar but listed for the sake of completeness*
- IGNORE = 1 Initial penetrations will be tracked, i.e., the slave contact surface is translated to the level of the initial penetrations and subsequently follow the master contact surface on separation until the unmodified level is reached
- IGNORE = 2 Initial penetrations will be ignored, i.e., the slave contact surface is translated to the level of the initial penetrations, optionally with an initial contact stress governed by **MPAR1**, *this is default*
- IGNORE = 3 Initial penetrations will be removed over time, i.e., the slave contact surface is translated to the level of the initial penetrations and pushed back to its unmodified level over a time determined by **MPAR1**
- IGNORE = 4 Same as **IGNORE = 3** but it allows for large penetrations by also setting **MPAR2** to at least the maximum initial penetration

The use of **IGNORE** depends on the problem, if no initial penetrations are present there is no need to use this parameter at all. If penetrations are relatively small in relation to

APPENDIX P

the maximum allowed penetration, then $IGNORE = 1$ or $IGNORE = 2$ seems to be the appropriate choice. For $IGNORE = 2$ the user may specify an initial contact stress small enough to not significantly affect the physics but large enough to eliminate rigid body modes and thus singularities in the stiffness matrix. The intention with this is to constrain loose parts that are initially close but not in contact by pushing out the contact surface using SFST and applying the $IGNORE = 2$ option. It is at least good for debugging problems with many singular rigid body modes. $IGNORE = 3$ is the Mortar interference counterpart, used for instance if there is a desire to fit a rubber component in a structure. With this option the contact surfaces are restored linearly in time from the beginning of the simulation to the time specified by MPAR1. A drawback with $IGNORE = 3$ is that initial penetration must be smaller than half the characteristic length of the contact or otherwise they will not be detected in the first place. For this reason $IGNORE = 4$ was introduced where initial penetrations may be of arbitrary size, but it requires that the user provides crude information on the level of penetration of the contact interface. This is done in MPAR2 which must be larger than the maximum penetration or otherwise and error termination will occur. $IGNORE = 4$ only applies to solid elements at the moment.

When eliminating penetrations by simulation for models with many parts, some parts may contain thin members that cause spurious self-contacts. These may be difficult to work around by only adjusting contact parameters, but fortunately there is rarely any loss of generality in ignoring contact within parts completely since those are usually not of interest in such a context. The option $IGNORE < 0$ was implemented for this purpose and is a way to approach this problem.

Damping

Damping can be activated in dynamic implicit analysis using VDC. A problem with contact damping in implicit is that the time step is usually large enough to not resolve the time in contact to get the desired damping effect. Often the situation becomes even worse, it is therefore not recommended to use damping.

TROUBLESHOOTING CONVERGENCE PROBLEMS

Convergence of the nonlinear equilibrium iteration process presents one of the greatest challenges to using the implicit mode of LS-DYNA. At risk of repeating what has already been mentioned, below are some useful troubleshooting approaches.

Eigenvalue Analysis

Many convergence problems in static implicit analysis are caused by unconstrained rigid body modes. These are created when an insufficient number of constraints are applied to the model, or when individual model parts are left disconnected. Eigenvalue analysis is an excellent diagnostic tool to check for these problems, both initially and at critical points in the simulation. The procedure for performing an eigenvalue analysis was discussed [Singularities and Eigenvalue Analysis](#).

D3iter Plot Database

To diagnose convergence trouble which develops in the middle of a simulation, get a picture of the deformed mesh. Adjust the d3plot output interval to produce an output state after every step leading up to the problematic time. An additional binary plot database named “d3iter” is available which shows the deformed mesh during each equilibrium iteration. This output is activated by

D3ITCTL = 1 to activate d3iter plot database

on *CONTROL_IMPLICIT_SOLUTION. View this database using LS-PrePost to detect abnormal displacements. The problem may become obvious, especially as deformation is magnified. If not, there is yet another flag to activate to get the residual forces into both this database as well as d3plot for fringing. Setting

RESPLT = 1 to get residual data to binary databases

on *DATABASE_EXTENT_BINARY will do just that. With this option the residual forces are output to the d3plot and d3iter databases for fringing under the “NdV” menu. This is a great tool for locating areas in the model where the residual forces are not being reduced to a satisfactory level and take appropriate actions.

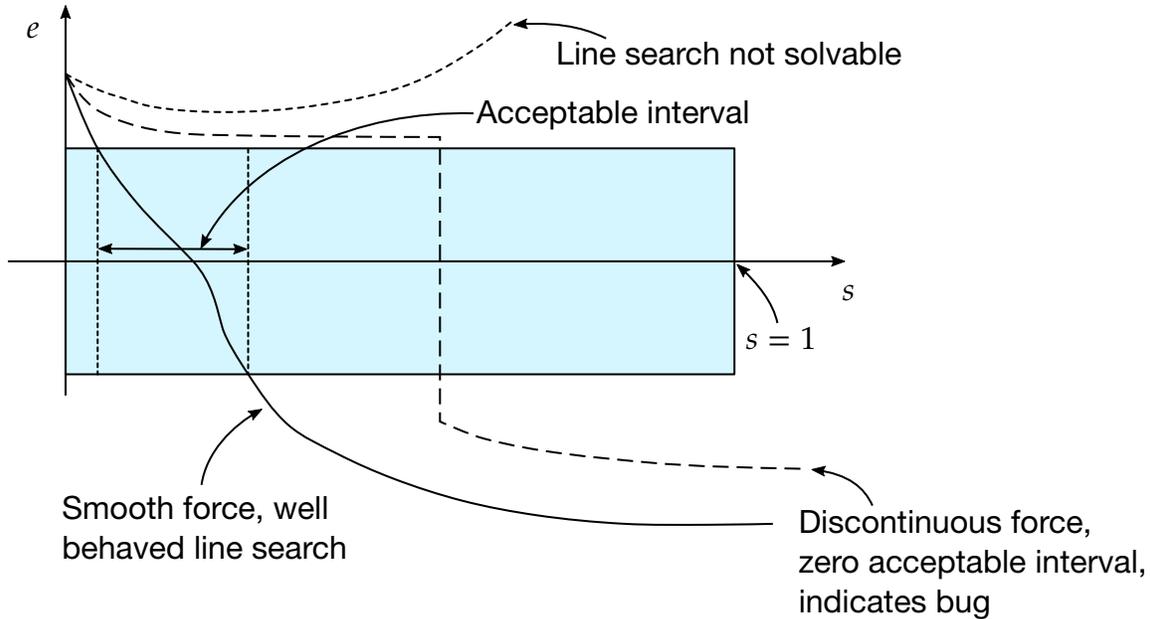

Taking Advantage of ASCII Information

If requested through [Output](#) on *CONTROL_IMPLICIT_SOLUTION and [Output for debugging](#) on *CONTROL_OUTPUT, a lot can be drawn from the information in the message file(s). This may be considered as a piece of advanced topic but may become useful in due time.

Residual Norm

Starting with the nonlinear output diagnostics, the following basic principle should be held in mind; *if the residual norm is zero, the problem is solved*. So it all comes down to make this number (11) small enough to trust the results. Therefore we suggest to monitor the residual norm and interpret it as an indicator of whether the convergence characteristics is good. Hopefully you would see this number decrease with implicit iterations and finally reach a relatively small number at convergence. Although it may (and will) increase on occasion, the trend should be a decreasing one. If this is a problem from the get-go, and you checked the model integrity through [Singularities and Eigenvalue Analysis](#) and common practice, it may be that a feature is not properly supported in implicit.

APPENDIX P

Line Search

Another thing to look at is the line search convergence (9), as the relatively loose line search convergence tolerance should render a reasonably small number of line search iterations. A rule of thumb would be less than 10, at most 20. If more is used, or if the line search does not converge, there may be something in the model causing a jump in the residual forces. This is not supposed to happen in implicit, and may suggest a bug. Either of the two following scenarios for a feature discontinuity (and many line search iterations) is possible

- The line search step size becomes ridiculously small, and the current residual norm (7) is not approaching the initial one (3).
- The interval in which the optimal step is to be found (8) becomes ridiculously small, and the residual norm on the left and right interval points are not approaching each other. This situation is depicted in the figure above (dashed line).

Many line search iterations can of course be due to high nonlinearities but if the above is observed it should probably be investigated, for instance by trying to identify model features that may be causing the bad behavior. If it is obvious that a discontinuity exist, like if the step size goes down to $\sim 1^{-100}$ or the interval size becomes zero, and it is not due to a model error, please send a bug report.

Stretching for Convergence

If the problem runs fine for a significant number of load/time steps with subsequent convergence issues, then the information received up to this point may be used intelligently and suggest a different (unorthodox) implicit strategy. To justify the approach, we begin by recalling that the convergence is detected by the following numbers becoming small; $d = \|\Delta u\|$ (displacement norm), $r = \|\mathbf{R}\|$ (residual norm) and

$e = |\mathbf{R}^T \Delta \mathbf{u}|$ (energy norm). But all these numbers are linked through the [General](#), $\mathbf{K} \Delta \mathbf{u} = \mathbf{R}$, so if \mathbf{K} reasonably “nice” at all times it doesn’t matter which numbers we use for detecting convergence. A mathematical way to state this is; if the condition number of \mathbf{K} is “good”, then all the norms are equivalent throughout the solution process. An intuitive statement would be to say that the problem is only moderately nonlinear, and convergence is usually never a problem. *But*, what happens if the properties of \mathbf{K} are not that nice, or if \mathbf{K} shifts character every time it is reformed? This is sort of saying that the problem is highly nonlinear, for instance due to frequent change of contact state or onsets/offsets of plasticity. In those cases the equivalence between d and r is lost, and typically an oscillatory behavior of the displacement norm is observed *even though the residual norm is reducing*, which in turn may lead to potential convergence problems just because the displacement criterion cannot be satisfied. Or equally bad, it could lead to [Premature Convergence](#) just by the coincidence that the displacement norm happens to become small. In those cases we essentially want to come up with a strategy where the displacement criterion is taken out of the convergence check and instead detect convergence based on residual only.

So assume we have say 10 converged states, after which the convergence problems begin. Then we can look at what the residual norm is for each of these converged states (11), for instance we may see the sequence

Step 1, residual norm 2859
Step 2, residual norm 1581
Step 3, residual norm 2119
Step 4, residual norm 2511
Step 5, residual norm 11570
Step 6, residual norm 4904
Step 7, residual norm 3586
Step 8, residual norm 3157
Step 9, residual norm 3315
Step 10, residual norm 2825.

For each of these steps we may validate the results, by post-processing contact force curves, checking force/moment balance etc., in LS-PrePost, and usually there is a correlation between “good results” and small residual norms. Step 5 above is for instance an outlier and may be associated with a prematurely converged step, something that can be confirmed or rejected from looking at the result. The goal with these observations is to establish a reasonable residual norm for which we can safely say that the results are good, and the numbers above indicates that 3000 may be a good candidate. The strategy is then to simply put $DCTOL = 1.e-16$ to ignore the displacement and set $ABSTOL = -3000$, which means we can be assured that convergence will not be detected until the residual norm is below 3000, and we “know” from having learned about the problem that this will yield good results. It should be

APPENDIX P

mentioned that this may not work if the character (force level) changes significantly later on in the simulation, as 3000 then may not be the number we would trust.

Contacts

Continuing with the [Output for debugging](#), a general rule is that there should be *no* warnings of large penetrations and preferably the maximum relative penetration should be below 90%. These numbers can be monitored after each load/time step. If large penetrations occur, either increase [IGAP](#) or contact stiffness, whatever makes most sense, but first make sure that the converged step is *really* converged (no [Premature Convergence](#)) by monitoring the residual forces and checking results as indicated above.

CHECKLIST

So, to summarize

- ✓ Activate implicit by setting `IMFLAG = 1` on `*CONTROL_IMPLICIT_GENERAL`
 - Set `DT0` to a reasonable initial time step
- ✓ Check possible singularities in an eigenvalue analysis by requesting `NEIG` eigenvalues on `*CONTROL_IMPLICIT_EIGENVALUE`
 - Find a way to constrain spurious modes
- ✓ Initially use dynamic analysis if rigid body modes are present in a static problem by setting `IMASS = 1` on `*CONTROL_IMPLICIT_DYNAMICS`
 - Use `TDYBIR`, `TDYDTH` and `TDYBUR`
 - Use numerical damping by putting `GAMMA = 0.6` and `BETA = 0.38`
- ✓ Only activate geometric stiffness contribution as a last resort, except for arc length methods
- ✓ Use default BFGS parameters `ILIMIT` and `MAXREF` on `*CONTROL_IMPLICIT_SOLUTION`
 - Increase or decrease `ILIMIT` based on convergence characteristics
 - Use full Newton (`ILIMIT = 1`) for hard problems
 - Keep `MAXREF` to a reasonably low number
- ✓ Use default convergence tolerances `DCTOL`, `ECTOL` and `RCTOL` on `*CONTROL_IMPLICIT_SOLUTION`
 - `ABSTOL` may be set to `1.e-20` to prevent premature convergence
 - Relaxing `DCTOL` may not necessarily result in better convergence
 - Future strategy may be to focus on residual
- ✓ Activate automatic time stepping on `*CONTROL_IMPLICIT_AUTO`
 - Set `DTMAX` to a number that resolves features of interest
 - Contacts
 - Material nonlinearities

- Frequencies
- ✓Use default line search method on *CONTROL_IMPLICIT_SOLUTION
 - Switch to LSMTD = 5 if hard problem (typically rubbers)
 - Don't change LSTOL
- ✓Use at least NLPRINT = 2 on *CONTROL_IMPLICIT_SOLUTION to get convergence diagnostics into log files
 - Use NLPRINT = 3 to thoroughly track the residual norm and monitor line search behavior if debugging model is necessary
- ✓Use *CONTROL_IMPLICIT_SOLVER only in special occasions
- ✓Set D3ITCTL = 1 on *CONTROL_IMPLICIT_SOLUTION to get a database with Newton iterates when debugging a model
 - Complement this with RESPLOT = 1 on *DATABASE_EXTENT_BINARY to get the possibility to fringe the residual force vector
- ✓For forming Mortar contact, make sure
 - Tools are oriented towards the blank
 - Contact on top and bottom of blank are separated among contact interfaces
- ✓Use part (set) definitions of slave and master in Mortar contact
- ✓Always use weak part as slave in a Mortar contact definition to get best possible convergence
- ✓Set SST to a reasonable characteristic length for slave side consisting of solid elements
 - With this option, separate solids and shells into different contact interfaces in order to not manipulate the contact thickness for shells
- ✓ If penetrations are large, activate penetration diagnostics on *CONTROL_CONTACT
- ✓To avoid release of contact pairs, either
 - Increase stiffness scaling factor SFS
 - Increase IGAP for progressive stiffness increase
 - Increase SST for solids while at the same time increasing SFS
- ✓Use IGNORE appropriately to deal with initial penetrations
 - Check initial penetrations in message file
- ✓Don't use contact damping

APPENDIX Q: User Defined Weld Failure

The addition of a user weld failure subroutine into LS-DYNA is relatively simple. The UWELDFAIL subroutine is called every time step when OPT = 2 is specified in MAT_SPOTWELD. As data, the identification number for the spotweld material, six constants specified in the input by thfe locations NRR through MTT, the radius of the cross section of the spotwelds, the current time, and the current values of the resultants for the spotwelds, which are stored in array STRR, are passed to the subroutine. The subroutine loops over the welds from LFT through LLT, and sets the values of the failure flag array FLAG.

APPENDIX R: User Defined Cohesive Model

The addition of a user cohesive material subroutine into LS-DYNA is relatively simple. The UMATiC subroutine is called every time step where *i* ranges from 41 to 50. Input for the material model follows the *MAT_USER_DEFINED_MATERIAL definition. The user has the option of providing either a scalar or vectorized subroutine. As discussed in the Remarks for the user-defined material, the first two material parameters are reserved to specify how the density is treated and the number of integration points required for the failure of the element.

The cohesive model calculates the tractions on the mid-surface of the element as a function of the differences of the displacements and velocities of the upper (defined by nodes 5-6-7-8) and lower surfaces (defined by nodes 1-2-3-4). The displacements, velocities, and the calculated tractions are in the local coordinate system of the element, where the first two components of the vectors are in the plane of the mid-surface and the third component is normal to the mid-surface.

A stiffness must also be calculated by the user for the explicit time step calculation in LS-DYNA. This stiffness must provide an upper bound on the stiffness in all three directions.

The material fails at an integration point when *ifail*=.true. For an element to be deleted from the calculation, the number of integration points specified by the second material parameter must fail. If the second parameter is zero, elements cannot fail regardless of the specification of IFAIL in the user-defined material input. For example, the user may choose to reject an implicit step if the displacement increment is too

For implicit analysis, the subroutine is called with *maketan*=.true. and the user must provide the elastic moduli in the three local directions in the respective diagonal terms of the *dsave* array. The parameter *reject*, if set to .true. by the user, will signal to LS-DYNA that the current implicit iteration is unacceptable. For example, the user may choose to reject an implicit step if the traction changes too much from the last time step. In this situation, LS-DYNA will print a warning message 'Material model rejected current iterate' and retry the step with a smaller time step. If chosen carefully (by way of experimenting), this may result in a good trade-off between the number of implicit iterations per step and the step size for overall speed.

The following example is a vectorized model with two elastic constants and failure:

```

subroutine umat41c(idpart,cm,lft,llt,fc,dx,dxdt,aux,ek,
& ifail,dtlsiz,crv,nnpcrv,nhxbwp,cma,maketan,dsave,ctmp,elsiz,
& reject,ip,nip)
include 'nlqparm'

```

APPENDIX S: User Defined Boundary Flux

A user defined boundary flux interface is provided in LS-DYNA where it is possible to define the thermal heat flux (power per surface area) in or out of a surface segment as an arbitrary function of temperature and history. The user may associate history variables with each individual flux interface and also use load curves.

The user flux interface is invoked using the keyword `*BOUNDARY_FLUX_OPTION`. This is accomplished with the parameter `NHISV`. When it is defined with a value greater than 0, the user subroutine

```
subroutine usrflux(f1,flp,...)
```

is called to compute the flux (`f1`) defined as heat (energy) per time and per surface area.

Other parameters that are passed to the user flux subroutine include the segment nodal temperatures at the previous (T_0) and current time (T_1), the segment nodal coordinates and the time integration parameter α . Also, the current thermal simulation time t , the time step Δt and average segment temperature (T_α) at time $t+\alpha\Delta t$ is provided together with the curve array for accessing defined load curves in the keyword input file. For computing load curve values, note that load curve IDs need to be transformed to internal numbers or the subroutine `crvval` should be used, see the appendix on user defined materials for details.

The segment coordinates available in the subroutine are such that the outward normal vector follows the well-known right-hand rule, thus segments corresponding to the lower surface of thick thermal shells are reversed before passed to the subroutine. For shells in general, the segment connectivity should follow the connectivity of the actual shell element to avoid problems.

Optionally, the user may define the derivative of the flux `f1` with respect to the average segment temperature (T_α) at time $t+\alpha\Delta t$, `flp`. This value is used in the nonlinear thermal solver for assembling the correct stiffness matrix and must be set by the user. If possible, it is recommended to use a value that reflects the nonlinearity of the flux model, otherwise the value 0 should be used.

An array of history variables, identical with the input parameters defined in the keyword input file, are passed to the subroutine that can be updated with time or kept constant throughout the simulation. An example of usage would be to integrate the flux with time to keep track of the dissipated energy per surface area in order to simulate the effects of spray cooling in hot-stamping.

APPENDIX T: Metal Forming Glossary

A TYPICAL DRAW DIE ENGINEERING PROCESS

Clay models of a new vehicle are scanned and the outer shell surfaces are created in a design studio. Body-in-white engineers and designers are responsible to create all the inner parts and various structure and underbody parts. Flanges are created on outer surface parts to be joined with the inner panels. These parts are typically created in the car axis; with global X-axis runs from the front to the back along the car's center line, global Y-axis from the driver side to the passenger side and Z-axis going straight up.

During the clay design and shaping, simultaneous and multidisciplinary engineering may be practiced involving divisions/departments from design, engineering and manufacturing. Material suppliers may also be involved in this stage for consultation if advanced materials are to be applied. Multidisciplinary involvement in this early stage of a vehicle development allows manufacturing engineers to capture any part designs with "no make" conditions that would be costly if they were allowed to proceed to a later stage; while design envelopes can be pushed to their maximum potential within the state-of-art manufacturing capabilities.

During the advance feasibility phase, parts from the design studio are processed quickly to go through an engineering process involving mainly the process engineer and FEA simulation engineer. Addendum and binder are roughly built in order to conduct a reliable draw die simulation. The exact process eventually would be used to build the die may not yet be established, therefore similar processes from knowledge base are used as references. Rarely are secondary dies (all dies except draw die) simulated. The main task here is to provide some quick assessment of the part's manufacturability through fast design/engineering iterations.

During the hard die design and construction phase, stamping manufacturing processes (some in three dimensional) are established, by referring to existing knowledge base, with necessary modifications needed for the current part design, and with the limits of manufacturing equipment such as press type, shut height, maximum tonnage and automation, etc. The stamping process includes the number of dies (to make a complete part of the final shape), part tipping, draw height, trimming (direct or aerial), flanging, springback compensation requirements, etc. Not all areas of the part may be formed to its final shape in one draw die. Some involve redraw die if one area of the part is especially deep compared to the rest of the part, which may otherwise cause uncontrollable wrinkles, splits, or exceed the draw height limit without the redrawing. Some areas of the part (which may have "undercut" or "die locked" conditions) may be unfolded to the addendum, then trimmed and flanged in a flanging die later. A typical example of such can be found along the hood line of a fender outer. There may be multiple trimming and flanging dies, since not all areas of the drawn panel may be feasible for trimming or flanging all in one trim or flanging die.

*APPENDIX T

Referring to [Figure 64-1](#), a typical draw die development process flow for an outer part is illustrated. The part is tipped from the global car axis to a 'draw die' axis, which takes into account of balancing the internal draw angles over the entire part, and minimizing the overall draw height, etc. Hem flanges are unfolded off the part breakline ([Figure 64-1](#)) in one of the following ways:

- 1)Tangent extension of the part surface,
- 2)Horizontal surface,
- 3)Vertical down-standing surface,
- 4)Any angled surface between horizontal and vertical surface,
- 5)To the addendum surfaces to be designed; in this case, the unfolding will happen after the addendum design is complete.

Flange unfold must take into account the trimming condition later in the trim dies. Direct trim represents the trim steel going down in a draw direction (vertical); while aerial (cam) trim steel covers all other directions, driven by a 'cam driver' driven further by the vertical downward motion of the trim die. There are specific trim angle requirements for direct and aerial trim operations. Next, the part boundary is smoothed, filling up any gaps, holes and sharp features. The boundary will likely be modified later during the addendum build. Binder is created, based on the unfolded part boundary and overall part curvature. A developable binder surface, which consists of planes, cylindrical surfaces or a combination of both, is preferred; however, in some cases a doubly curved binder surface (undevelopable surface) must be designed for the purpose of reducing the draw depth at critical locations for material utilization, alleviating thinning, or both. Theoretical punch opening line (P.O. line, Detail #2 in [Figure 64-1](#)) can be offset from the smoothed part boundary in the plane normal to the draw axis, projected to the binder surface in the draw direction; some smoothing of the P.O. lines may be required. Generally, the finished P.O. lines should be consisted of mostly straight lines and radii, with generous transition among corners. P.O. lines do not follow tight corners, avoiding formation of wrinkles during the draw. In addition, design of P.O. lines must take into consideration the material utilization issue, especially in the blank sizing critical locations. Once P.O. lines design is complete, binder surfaces inside of the P.O. are trimmed and the remaining binder surface design is sent for binder closing simulation. Given a blank initial shape, simulation of the binder closing action can determine the quality of the binder design. Typically, for exterior outer panels, no buckles or wrinkles are allowed during the closing; for inner panels, some wrinkles are acceptable, or even desirable, depending on the part shape. Lower punch/post support may be introduced to reduce the draw height, alleviate thinning, or remove the initial blank drape into the binder cavity. Based on the binder closing simulation results, unacceptable binder design is sent back for rework, and the satisfactory binder design proceeds into the next step of addendum build, which is used to fill the space between the part boundary and binder surface. It is noted that the P.O. lines may need to be adjusted during the addendum design. The trimming condition may also be affected and modified during the addendum design. Next, draw simulation ensues, assessing the overall formability of the draw design. If

quality targets are not achieved in the simulation, the process may go all the way back to the tipping for redesign/reprocess; otherwise successful simulation will direct the draw surface design to the next stage of draw die structure design.

TYPES OF DRAW DIES

There are many different types of draw dies used to punch the part to their intended shape, as shown in [Figure 64-2](#). They basically can be divided into either single action or double action dies. Specifically (names may vary among different companies),

- 1) Air draw – Single action. It is a 3-piece die system with 1 piece upper (cavity) and 2-piece (binder and punch/post) lowers. The upper cavity (driven by press ram) moves down in one action to close with the lower binder, and then closes with the lower punch to draw the part to the home position. The lower binder is either sitting on an air cushion through pins that go through the press bed, or directly on nitrogen cylinders arranged uniformly between the bottom of the binder structure and the press bed; the punch is fixed onto the press bed. This is the most popular draw type, mainly because of its speed and efficiency. Its limitation includes a maximum draw height of 10”.
- 2) Toggle draw – Double action. It is a 3-piece die system with 2-piece upper (binder and punch) and 1 piece (cavity) lower. Upper binder, driven by the outer ram of the press, moves down to clamp the blank with the lower cavity; then the upper punch, driven down by the inner ram, closes with the lower cavity to complete the draw. Since this adds another action, it is slower than the air draw; however, this type of draw die is well suited to control the wrinkles created during the forming of difficult part, such as liftgate and door inner. Furthermore, this type of draw has a relatively large draw height, which is limited only by the press.
- 3) Air draw with pressure pad – Single action. This is very similar to 1), except an additional pressure pad, driven by nitrogen cylinders mounted on the upper die structure, closes first with the lower punch, then the entire upper comes down to finish the draw. This is similar to 1) in efficiency.
- 4) Stretch Draw (four piece) – Double action. It is a 4-piece die system with 2-piece uppers (upper binder and punch) and 2-piece lowers (lower binder and cavity). Upper binder moves down to close with lower binder, moving together for a certain distance (up to 2”), then upper punch comes down to completely close with lower cavity. Finally the binders move down together to their home position. This process is not used as often as 1), 2) and 3), however, it is very capable in forming difficult inner parts, especially those prone for wrinkles, such as liftgate inner, door inner and floor pan. Since there is a ‘pre-stretch’ action with the binders clamping the blank and moving down together, strain path change in the part during the forming is expected. This is the slowest draw type.
- 5) Crash Form Die – Single action. It is a 2-piece die system with no upper or binders. Upper and lower tool takes the same shape, with upper moving down to close with the lower tool. This is obviously a very simple die, which can

*APPENDIX T

handle simple parts, with not too much draw depth variation (near constant draw depth all around).

TYPES OF FLANGING DIES

There are three types of flanging dies, as shown in [Figure 64-3](#). All three types have a fixed lower (trim) post upon which the drawn (or partially trimmed part) is sitting, and a pressure pad (or multiple pads) which holds the part (which is loaded onto the post in a vertical direction) in place against the post. In a direct flanging process, the flanging steel ([Figure 64-3](#)) moves vertically down to 'wipe' or 'bend' the part to its flanged position. In an aerial flanging process, the flanging steel moves to form the flanges in an angle rather than the vertical direction. The steel is held by the cam slide, driven by a cam driver which in turn is driven by the trim die's downward movement. Since the finished flange forms a 'die lock' condition, meaning the flanged part will not be able to be lifted (retract) out of the trim die into the next die (or station), the filler cam ([Figure](#)) is moved horizontally out of the way so the part can be lifted up and out. Once the part is removed, the filler cam moves back into its home position ready for the next drawn panel to be loaded. In the rotary cam flanging process, the filler cam is called a 'rotor', which rotates out of the way for the flanged part to be lifted up and out. Some parts of the rotary cam flanging design are a patented process. In comparison to the conventional cam flanging, rotary flanging has the advantage of being very compact.

TYPES OF HEMMING DIES

There are two types of hemming dies, as shown in [Figure 64-4](#). Both processes have a fixed hemming bed, on which the flanged outer part is loaded; the inner panel is then loaded onto the outer panel; proper clamps are applied to hold tight the panels together and in place. In press (or table top) hemming, a pre-hemming tool is moved to form the flange into a halfway position, followed by the final hemming tool pressing down on the flange against the inner and outer panels to its final position. Many different shapes of hem tips can be achieved, as shown in the figure. In roller hemming, a pre-roller moves in a three dimensional curvilinear path following the hem tip, to form the flange partially. This is followed by a final roller, moving in another three dimensional path, to finish the hem shape. In the hemming of complex or high-end parts, many passes (rollers) are needed to achieve high quality hem surfaces. Similarly, with the design of different roller shapes, many shapes of hem tips can be achieved.
